1.—Howard A. Kelly goes very carefully into the history of antiseptics, dividing the honor of its introduction among several investigators, giving a large portion of the credit to Jules Lemaire, who in 1863 published a very comprehensive work on the use of carbolic acid. Coal-tar had been used for many years in a powder or paste as a disinfectant for hygienic purposes, and was first put up in an emulsion by Le Beuf in 1850 and experimented with by Lemaire, who showed that "In surgery he established the great principle of a living septic agent in putrifying and suppurating wounds, and he laid the foundation stone of successful treatment." Lister's first publication on the use of carbolic acid was published in 1867. [J. H. G.]

2.—Henry P. Neuman prefers to call the operation of amputation of the cervix uteri *tracheloplasty*. He thinks this operation much to be preferred over the curette, the cautery and other methods which are always more or less unsatisfactory. The author then describes his own particular method of amputating the cervix, which is illustrated by a number of cuts showing the steps of the operation. [J. H. G.]

3.—Shepards maintains the view that colds are due to an inactive condition of the excretory organs, resulting in imperfect elimination through the normal passages and causing a discharge of some of the impurities of the system, through the respiratory mucous membrane, particularly of the head. In the treatment of a cold, he recommends abstinence from food for 24 hours, flushing of the bowels with warm water, exercise in the open air, and a Turkish bath. A simple "cold in the head" may be treated by drawing hot water in the nostrils several times, and then blowing it out. This measure is simple and effective. Cold bathing in the morning is recommended for those in fair health as a measure to avoid colds. [F. J. K.]

4.—Ward in an article on atrophy of the gastric mucous membrane, states that he does not believe the condition is essentially associated with pernicious anemia, as most authors do. He holds that we can only diagnose achylia gastrica, when there is complete absence of all the normal

constituents of the gastric juice, and only after this condition has been found, after repeated examinations, at various times. He lays particular stress upon the fact that the disappearance of free HCl does not necessarily point to gastric carcinoma, for in cancer of the stomach it may be present in the gastric juice and may be absent in some cases of acute and chronic gastritis. A report of 5 cases of atrophy of the gastric mucous membrane is given. He emphasizes that diarrhea, as a rule, exists with achylia gastrica. The important indication in the treatment, in addition to general hygienic measures, will be found in regulating the diet; the patient should be urged to take large quantities of farinaceous food; a mild astringent, such as tannigen or tannalbin, will be found serviceable, and for the anemia iron is indicated. When there is much mucous in the stomach he recommends lavage. [F. J. K.]

5.—Makuen reports 2 cases of **voluntary laryngeal whistling**, and he states that the subject is of interest as showing the possibility of development of voluntary laryngeal muscle action. [F. J. K.]

8.—W. H. Earles urges upon the surgeon the more careful study of methods of making accurate **diagnosis of intra-abdominal lesions**, maintaining that "Surgeons too often take things for granted and develop conclusions without first having established the proper premises." He particularly recommends the careful consideration of the history of the patient and the development by constant practice of the sense of touch. He thinks that although in some cases an anesthetic is of assistance that in many others it really obscures the condition by removing the evidences of sensitiveness and pain of the diseased organ. [J. H. G.]

9.—Reed, in an article on the **study of mountain fever**, draws the following conclusions: In the majority of cases of mountain fever, the Widal test is negative; the duration of mountain fever is shorter than that of enteric fever; the exciting cause does not seem to be Eberth's bacillus; the exacerbations and remissions of temperature in mountain fever are more abrupt than in typhoid fever; the eruption of mountain fever has a peculiar "spotty feeling;" it is raised, does not disappear upon pressure, and covers the entire body. [F. J. K.]

10.—Waxham states that the **oxygen-carrying-capacity of the erythrocytes is lowered in neurasthenia**, and that there is poor vaso-motor control of the vascular system, giving rise to variation in the peripheral blood. [F. J. K.]

11.—F. E. Waxham rehearses a number of interesting and amusing experiences in the early practice of **intubation**, showing the great popular prejudice against this operation when it was first introduced. He calls attention to the wonderful change in the **mortality of diphtheria** since this operation has come into vogue and since the antitoxin treatment has become thoroughly established. [J. H. G.]

12.—Herrick, in an article entitled **some points in the diagnosis of gall-stones**, gives an analysis of some of the important symptoms of gall-stone colic. The pain may be referred to the back, or it may be located to the left of the median line of the abdomen, or the pain may radiate upwards or shoot downwards toward the genitalia. Jaundice follows in great a number of the cases of biliary colic, but in some the icterus is slight, so that it may be overlooked, and there are cases in which no evidence of jaundice is to be discovered. There is a large class of cases in which inflammation follows the passage of gall-stones through the duct. Vomiting and nausea, pain and tenderness over the gall-bladder are present, and upon examination the gall-bladder is found distended. The author states that the exact nature as to the causation of Charcot's hepatic intermittent fever has not been determined. Intermittent hepatic fever, accompanied by chill and sweating, does not only occur in association with the passage of stones through the biliary duct, but has also been observed in cases of carcinoma, which produce pressure upon the common bile duct. The association of gall-stones with carcinoma can hardly be looked upon as a mere coincidence, as gall-stones precede the development of carcinoma in many cases. Reference is made to Riedel's tongue-shaped process—a pericyclic thickening of the gall-bladder extending from the anterior border of the liver as indicating a gall-bladder stone in many cases. The author states that the occurrence of enteric fever seems to predispose to the formation of gall-stones in many instances. Reference is made to the differential diagnosis between gall-stone colic when the

pain is referred to the left side and angina pectoris. Arteriosclerosis, hypertrophy of the heart, violent, distinct precordial pain, which radiates to the neck and left arm, with a sense of impending death, points to angina pectoris. The differential diagnosis between biliary colic and senile pneumonia is often difficult, especially when the right lower lobe is affected and the cough is slight with little expectation. The author also refers to the difficulty in differentiating certain case of localized peritonitis, appendicitis, intestinal obstruction, hemorrhagic pancreatitis, Dietl's crisis in floating kidney, hysteria, and malaria with neuralgic pain and jaundice, from gall-stone colic. [F. J. K.]

13.—Samuel Lloyd, continuing the **present status of spinal surgery** discusses the question of tumors. The surgical treatment of tumors of the spine dates back to '87, and owes its origin to Gowers and Horsley. Lloyd reports briefly a collection of 51 cases. He reports a case of hydatids which produced compression of the cord and in which he operated with complete recovery, the patient being able to return to his ordinary occupation. Many of the deaths following operations for tumors of the spinal cord are really due not to the operation but to the nature of the growth. Only 8 per cent. of the cases operated upon have died as a direct result of the operation itself. **Fractures of the spine** are next discussed. Recoveries from operative interference in the cervical region of the spine have been very few, the prognosis in the lumbar and dorsal regions is much better. The nature of the fracture itself will also influence the prognosis; for instance, where there is complete severance of the cord, as evidenced by the rapid appearance of bedsores, paresis of the bladder and rectum, and obliteration of the deep reflexes, operative interference would hold out little hope of benefit. The author, however, does not agree with Keen that where deep reflexes are absent operative interference is contra-indicated, because a number of cases are on record where the reflexes have been absent and yet there has not been complete severance of the cord, and improvement has followed laminectomy. Statistics show that most of the deaths following fracture-dislocation of the spine occur within a few days, and hence, the number of deaths which are attributed to the operation would undoubtedly have taken place even though no operation had been performed. As to the best time at which to operate Lloyd thinks that it is best to wait until the patient recovers from the shock and until it is evidenced that there will be no spontaneous recovery complete enough to make life bearable. If the patient shows a tendency to gradually improve after the injury, operation should not be done, but where the symptoms show progression or seem to have reached the end of improvement operation should be undertaken. [J. H. G.]

7. The Prevalence of Streptococci in Cow's Milk. D. H. BERGEY.
8. Case of Congenital Form of Hernia of the Appendix Vermiformis in Connection with a Cyst of the Canal. G. CHILDS MacDONALD.

1.—Howard A. Kelly deals with those cases of **appendicitis** in which the appendix is found to be densely adherent, or when it opens into an abscess, or when there exists a more or less general peritonitis. In all such cases the operator dreads all avoidable contamination of the surrounding tissues with any part of the appendiceal abscess, and all avoidable injury to the coats of the adherent intestine. Kelly has found that when the appendix is diseased and densely adherent at its tip, that the best plan often is first to seek out and expose its base, which

is detached and divided so as to free the appendix from the cecum. The distal portion is now wrapped for protection in gauze, while the opening into the bowel is closed. Then the severed appendix is dissected out of its bed with much greater facility than was possible with both ends anchored, one to the cecum and one to the adhesions. This plan of procedure is especially useful in the gynecological field. In cases in which the vermiform appendix is attached to a pyosalpinx, or an ovarian, or fibroid tumor, after it is severed from the bowel, it can then be enucleated with the pelvic abscess or with the tumor. When the end of the appendix enters the abscess cavity surrounded by the adherent intestine, which cannot be stripped off with safety, Kelly, after freeing the base of the appendix from cecum traced it up until it entered an abscess cavity under the ascending colon. It could not be separated from the adhesions without injuring the bowel so the appendix was grasped with a pair of forceps, on either side, close to the abscess and split open and followed to its lumen, as a guide, by using a groove director and a pair of open scissors, with one blade in the appendix. The operator was thus enabled with certainty to enter the very middle of the abscess cavity, to lay it open and cleanse it out without doing any damage to the colon. [T. L. C.]

2.—(Will be abstracted when concluded).

3.—DeForest Willard presents skiagraphs of a case of congenital deformity of the wrist in which osteotomy of the radius was performed. The patient was a girl of 14, whose carpus was thrown by the arched condition of the radius so far out of the normal line anteriorly that it entirely failed to articulate with the ulna, and was joined very faultily with the radius. The resulting disability was so great, and continued to grow greater every year, that the simplest exertion could not be performed with comfort. The mother had the same deformity in both wrists but in a less degree. The arch in the radius caused its articulating surface to look almost at right angles to its normal position, while the semilunar and scaphoid lay with their sides against the joint surface instead of upon their normal faces. An osteotomy of the radius $1\frac{1}{2}$ inches above the wrist joint, with forcible straightening and fixation for 5 weeks in a corrected position with plaster of Paris gave a greatly improved result both as to appearance and strength. [T. L. C.]

4.—J. C. Hemmeter discusses the logic of hydrochloric acid therapy, and restoration of lost gastric HCl secretion by medical and surgical methods. The purposes for which HCl are given are: the absence, or the diminution of, normal secretion; to supplement gastric proteolysis; to act as an antiseptic; to act as a tonic and stomachic. He reports a case of immense atonic dilatation of the stomach in which the greater curvature extended into the pelvis. Every morning before breakfast stagnating food masses could be washed out of the stomach. Analysis of the stomach contents could never detect free or combined HCl. The ferments pepsin and chymosin were still active in their precursory stages. After 6 months of medical treatment no lasting improvement was effected. The operation of gastroplication was then advised and performed, and nephrorrhaphy, which was indicated, was also performed 5 months after this operation free HCl was detected after the test meals. This was an evidence that the glandular layer had not been destroyed by disease but that the peptic cells had simply been exhausted by the presence of food in a dilated stomach which could at no time empty itself entirely. [T. L. C.]

5.—Carl Beck contributes a paper on metatarsal fracture. Before we had resource to the X-rays, as a method of diagnosis, metatarsal fracture must have been frequently overlooked. If only one or two metatarsal bones are broken but little tendency to displacement is present, which explains why the symptoms are not pronounced. After discussing the diagnosis of the condition Beck takes up the question of treatment. If there is no displacement present in fracture of any of the second, third or fourth metatarsal bones, a simple and short plaster of Paris dressing meets the requirements. The patient should be kept in bed the first week and during the next two weeks should be encouraged to walk, protected by the proper ambulatory dressings. If the first, or fifth, metatarsus is broken, and no displacement is noticeable, a small strip of moss-board slightly moistened is placed alongside the outer, or inner margin, of the foot before the plaster of Paris dressing is applied. If there is displacement of the second, third

or fourth metatarsal bone pressure will then reduce the fragments, which are then kept in place as indicated in the other condition. If the displacement is sideways (instead of in the dorsal or planter direction) reduction is best accomplished by grasping the fragments as firmly as possible near their epiphyseal end and alternately turning and shifting them until the reposition is perfect. [T. L. C.]

6.—In this contribution on inguinal colostomy William J. Mayo concludes as follows: Colostomy is not now a rival or excision of the rectum for malignant disease, and should only be employed in hopeless cases presenting obstructive phenomena. For a permanent colostomy the combination of Wyeth's and Bailey's methods gives a satisfactory result. Colostomy, preliminary to excision of the rectum, should be located high on the colon to give sufficient length to the sigmoid to permit restoration of the continuity of the bowel. For ulceration, and other conditions in which the upper limit of the disease is not definitely known, the interior of the bowels should be explored through the inguinal incision in order to determine the proper site of the opening. Right-sided colostomy has an increasing field of usefulness in amebic dysentery, chronic colitis and allied conditions. [T. L. C.]

7.—D. H. Bergey reports on the prevalence of streptococci in cow's milk. During the past summer in 40 samples of market milk examined, 90% were found to contain micrococci, and in 50% of the samples, streptococci were found. Of 16 samples of milk collected from a well conducted dairy, only 12.5% contained micrococci, and only 6.25% contained streptococci. Of 28 samples collected from another of the best dairies only 17.8% contained micrococci, and no streptococci were found. In another first-class dairy in which 7 samples of mixed milk were examined 65.71% contained micrococci and 28.57% contained streptococci. In still another of 8 samples examined 62.5% contained micrococci, while none contained streptococci. These bacteriological examinations illustrate that extreme cleanliness is necessary in order to produce milk containing less than ten thousand bacteria per cubic ccm. This care will also tend to the exclusion of the extraneous bacteria from milk. [T. L. C.]

VRATCH.

February 24 (Vol. XXII, No. 8).

1. On the Etiology of Large Infants. B. N. AGAPHONOW
2. On the Treatment of Tetanus. M. I. ROSTOWTSEV.
3. The Primary Stages of Cardiac Affections in Military Men. D. I. VIERUSHSKY.

1.—Agaphonow gives an exhaustive review of the literature on the subject, citing observations of various authors as to the normal and excessively large weights of infants at birth. One of these infant-giants observed by Blach weighed 12,000 grms. The case reported by the author is that of a woman, 34 years old, in her fifth labor, who, after considerable difficulty, was relieved of a female child weighing 5950 grms. and measuring 58 cm. The difficulty experienced in this case was due to the fact that while the comparatively small head was delivered without any trouble, the shoulders remained impacted within the vagina, the left shoulder pressing firmly against the pubis. The cord was wrapped around the child's neck, the child having died of asphyxia. After considerable effort the shoulder was finally released by downward traction, and delivery accomplished. The placenta, delivered by Shultze's method, weighed 1190 grms.; the cord was very thick and measured 86 cm. The mother of this child was a large woman with quite a roomy pelvis. The father was also a large man. From this and similar cases, the author concludes that large children are born of large parents, and that the difficulty in these cases is not in the delivery of the head, as is usually the case, but the shoulders. [A. R.]

2.—Rostowtsev points out that the frequent disappointments following the administration of antitetanic serum are to be attributed to the fact that the tetanus-toxins combine chemically with the nerve cells, and the antitoxin neutralizes only those toxins which are circulating freely in the blood. By the time the patient comes for treatment a considerable amount of toxin has already entered into combination with the nerve-cells, and is therefore beyond

reach. Antitetanic serum, therefore, is really a prophylactic, and not a curative agent. He reports the following two interesting cases: In one, a factory woman, 38 years old, received a severe injury of the right thumb. Two weeks later she developed tetanus, which at first was localized in her right upper extremity, but soon became generalized. She received 50 c. c. of tetanus-antitoxin on each of three days. She made a slow recovery, still showing some rigidity of the facial muscles on the 65th day of the disease. The peculiar feature in this case is that the tetanus developed at first locally, which is rarely the case in man. That the antitoxine as responsible for the cure is proved by the fact that on the days when no injections were made, the symptoms were considerably aggravated, while on the other hand marked improvement followed each injection. The second case was in a peasant girl, who developed what turned out to be a very severe attack of tetanus, but gave no history of trauma. However, her body was found covered with scratches, some of which may have served as the point of infection. Not having any antitoxin on hand, and hampered by the expense, the author decided to try normal brain tissue. On the second day after her admission, 10 grms. of pigs' brain rubbed up in 30 c. c. of normal salt solution were injected subcutaneously, the brain emulsion as well as the skin being in a thoroughly aseptic condition. Some improvement followed. The injection was repeated on each of two following days, and again on the ninth day, calf's brain being used on one occasion. Like in the first case, the symptoms were aggravated considerably at the intervals between the injections, thus proving that the latter were exerting a beneficial effect. The patient finally recovered. It is noticeable that in this case Kernig's sign, considered pathognomonic of meningitis, was observed. The author concludes by advising urgently the use of normal brain-emulsion in cases in which the serum cannot be obtained. The injections, if carried out under strict asepsis, are perfectly harmless. [A. R.]

3.—Vierushsky has observed a number of cases of cardiac diseases in recruits and soldiers, which could not be detected by the usual signs, and were, in many instances, discovered accidentally. The 45 cases studied by him can be divided into three groups: 1. Those in which the typical manifestations of cardiac disease were present (20); 2. Those which did not present a complete clinical picture (17); 3. Those in which there was a constant murmur at the apex, but no other symptoms (8). Owing to the complicated mechanism of the first sound, a murmur, immediately following, but not replacing it, is recognized with difficulty in the first stages of the disease. The method usually employed of having the patient make active movements so as to accentuate both the normal sound and the murmur, is also liable to error, inasmuch as by the exercise the two sounds of the heart follow each other in such rapid succession that the murmur may escape detection. A much more satisfactory method is to examine the patient in a recumbent position. The action of the heart is slower, but the sounds are more distinct. In this case no previous exercise is necessary, inasmuch as in this position the blood-pressure is raised. In some cases it may be found necessary to slow the heart and thus render the sounds clear by appropriate medication. Of the other clinical signs hypertrophy of the ventricle and accentuation of the second sound in mitral insufficiency was sufficiently marked to be recognized only in a few cases. Epigastric pulsation and displacement of the apex-beat served as useful indication in many cases. The changes in the pulse, both in rate and volume, were not constantly observed. These, however, may be present in persons with sound hearts and invariably accompany neurasthenic conditions, thus rendering their presence of little diagnostic value. Likewise, the changes in blood-pressure are of slight diagnostic significance. As to the etiology, it was found that rheumatism is by no means the only factor. In many cases the cardiac affection followed some acute infectitious disease, such as typhoid fever, smallpox, inflammations of

the lungs, diphtheria, etc. In quite a number of cases the disease developed apparently without any cause and entirely unobserved by the patient. It has been also observed, as it might *a priori* be expected, that the service in the army tends to make the progress of any cardiac affection much more rapid. [A. R.]

March 3, 1901 (Vol. XXII, No. 9.)

1. Five Hundred Operations for Cataract. S. N. KORSHENIEWSKY.
2. A Case of Repeated Extra-uterine Pregnancy. D. D. SANDBERG-DEBELE.
3. A Case of Diabetes in a Nursling. N. A. ORLOW.
4. A Case of Diabetes in a Boy, 3 1-2 Years Old. W. I. NOSKOW.
5. Poisoning by Cream-tarts in Charkow. P. N. LASH-ENKOW.

1.—S. N. Korshenewsky performed 500 cataract operations with the following results: Good vision was obtained in 348, or 17.2%; medium in 61, or 13.5%; weak in 17, or 3.8%; vision lost in the affected eye in 25, or 5.5%. The results in 49 cases are not reported. The operations were performed under various circumstances, in hospitals as well as peasants huts. The condition of the eye was also variable, almost all forms of cataract with their usual complications being represented. Iridectomy was employed in every case. The author insists on thorough asepsis and antisepsis. [A. R.]

2.—D. D. Sandberg-Debele reports the case of a woman 34 years old who was operated for extrauterine pregnancy in the right tube. About 14 months later she presented a recurrence of the symptoms accompanying her last pregnancy and fluctuating pelvic tumor on the left side. No improvement having followed the usual treatment, the tumor, was incised through the posterior vaginal wall and a considerable amount of clotted blood removed. The patient made good recovery. In speaking of the frequency of extrauterine pregnancy, the author mentions the fact that out of 3873 gynecologic case in the Maryin Hospital there were 130 extrauterine pregnancies (3.4%). As to treatment, 113 of these cases were treated without operation. 28 recovered entirely, while 85 left the hospital very much improved but with an encapsulated hematoma in the pelvis. 17 patients were operated on. In 5 laparotomy was resorted to, while in the other 12 the tumor was evacuated through the posterior vaginal wall. Every one of the latter made an uneventful recovery. The author prefers the vaginal route as the most convenient, the simplest and safest, especially so in cases where hospital facilities cannot be obtained.

3.—N. A. Orlov reports a case of diabetes in an infant 4-5 months old, left at the Foundling Asylum. The urine contained large quantities of sugar as determined by Trommer's, Nylander's and the indigo tests. The cardinal symptoms of diabetes, namely, polyuria, polyphagia and autophagia were present. The child also had a number of boils on its body. The little patient died on the 12th day. The autopsy revealed an acute broncho-pneumonia with pulmonary edema, acute intestinal catarrh, edema of the dura and a serous effusion in the third ventricle. The latter, according to the author, was the etiologic factor in the disease. The claim is made that this is the first case of genuine diabetes in an infant recorded. [A. R.]

4.—W. I. Noskow reports the case of a boy 3 1-2 years old who after an attack of gripe developed an enormous appetite, extreme thirst, emaciation, debility and polyuria. The urine was found to contain 4.8% of sugar and acetone. The boy was going down rapidly and finally died in a state of coma which lasted for 48 hours. As to the probable etiology in this case, the author believes that hereditary syphilis played an important part. The child's father suffered for a number of years and finally died from syphilitic affection of the nervous system. The attack of gripe which the boy had served as the exciting cause. [A. R.]

5.—Will be abstracted when completed.

ZEITSCHRIFT FUER HEILEKUNDE.

February, 1901. (Vol. 22. No. 2.)

1. Experimental Investigations in the Study of Poisoning. VON CZYHLARZ and DONATH.
2. Clinical Observations upon the "exertion interval," from Retardation of the Pulse, and its Significance in the Diagnosis of Mitral Insufficiency. R. SCHMIDT.
3. Malignant Tumors of the Lungs. M. WEINBERGER.

1.—Von Czyhlarz and Donath divide poisons into bacterial poisons and others. Their investigations include only the other poisons, the alkaloids, etc., especially in relation to their effect upon the liver. From a review of the literature of the subject, it is clear that the liver in some way diminishes the virulence of poisons. Three series of experiments were performed, 72 in number. In the first series an emulsion of liver, spleen, kidney, and brain, was made, and tests made with each, by injecting them with strychnin in toxic dose, into animals. These experiments showed distinctly the power of the animal organs, in emulsion, to lessen the effect of the poison. The longer the emulsion and poison were allowed to mix before injection, the less was the effect of the poison. More experiments showed plainly that the richer the emulsion in cells of the organ, the more active was the resistance of the organism to the poison. Blood had the same effect, while blood serum had none at all. In the second series, a solution of strychnin was passed through the liver of an animal before being injected into another animal. Here also the poison had far less effect after being conducted through the liver. In the third series an extremity was ligated, strychnin injected, and the ligature only removed four hours later. In spite of the toxic dose of strychnin injected, not one of the animals showed bad results. From all of this, von Czyhlarz and Donath conclude that the power of decreasing the activity of a poison lies in the cells of the animal organs. And that all tissue has some such power is shown by the last experiments. The liver undoubtedly possesses this power to a very large degree. [M. O.]

2.—About 40 years ago Marey first noticed that there was an interval between the beginning of systole (the apex-beat) and the beginning of the pulse wave in the aorta of about one-tenth of a second. Martius called this the "closed interval" (*verschlusszeit*), while the "expulsive interval" (*austreibungszeit*) follows sharply after it, each occupying half of systole. The "closed interval" was later called "exertion interval" (*anspannungszeit*). Martius believed that the length of the "closed interval" could be measured from the apex-beat. When the apex-beat was protracted, the "closed interval" was lengthened. Schmidt reports the case of a woman of 60, who had had rheumatism. Cardiac symptoms developed four years ago. Examination showed orthopnea, widespread cyanosis, ascites, and edema. A diffuse pulsation existed over the heart and epigastrium; the apex-beat was heaving, not circumscribed. A long systolic murmur covered the first sound, the second sound being dull, ending in a short rumbling diastolic murmur. The pulmonary second sound was markedly accentuated. At the aortic cartilage, low systolic and diastolic murmurs were audible. Over the sternum a loud blowing murmur was heard. There was great hypertrophy. Both the apex-beat and the impulse of the heart were plain. The autopsy, held two months later, showed stenosis and insufficiency of the mitral valves, with insufficiency of the aortic and tricuspid valves. Though the "closed interval" was wanting, both the apex-beat and the impulse of the heart were present. After a long discussion, with a complete review of the literature of the subject, Schmidt concludes that the apex-beat, or impulse of the heart, is in no way related to the "closed interval," nor does it necessarily occur in time with the "closed interval;" that with regard to the retardation of the pulse after the apex-beat, lengthening of the "exertion interval" will eventually be noted clinically; that in many cases of organic mitral insufficiency, whether well compensated or following acute rheumatism, the pulse will be strikingly retarded after the apex-beat, and is caused by the mitral valves remaining open during systole; that this symptom is not pathognomonic of mitral insufficiency; but that, in difficult cases, it may be an aid in the differential diagnosis between uncomplicated mitral insufficiency and hemic murmurs. [M. O.]

3.—Malignant tumors of the lungs may be sarcoma, en-

dothelioma, or carcinoma. The two former are very rare, and generally metastatic. Primary carcinoma arises from the bronchial mucous membrane. Diagnosis during life is seldom made. Weinberger reports two cases of primary bronchial carcinoma, one of which ran a course almost typical of tuberculosis, with symptoms of a bronchial tumor later; the other patient expectorated pieces of a tumor which were diagnosed microscopically. A third case is added, of sarcoma of the mediastinum which had grown into the lung. Roentgen photographs were made of all three cases, showing malignant tumors of the lungs, proved by autopsy. In the first case, a man of 42, who had been ill about one year, typical signs of beginning phthisis appeared in the right apex; followed later by a distinct difference, under the Roentgen ray, between the movements of both sides of the diaphragm, the right side moving far less than the left. The large shadow of the tumor was upon the right side. Autopsy showed carcinoma of the upper lobe of the right lung, starting from a bronchial twig, embracing the right bronchus, trachea, left bronchus, esophagus, superior vena cava, pleura, second and third ribs, and the bronchial glands. The second patient was a man age 52. Examination under the Roentgen ray showed a right sided tumor of the pleura or lung. At the autopsy carcinoma of the right bronchus, with numerous metastases was found. The third case was a girl of 20, in whom a mediastinal lymphosarcoma had grown into the upper lobe of the left lung. This was shown both by the Roentgen photographs and by the autopsy. Roentgen photographs will aid materially in the differential diagnosis of thoracic tumors. Adhesion of the pleural surfaces, effusion into the pleural sac, atheroma of the aorta, and the consistency of a tumor may sometimes be diagnosed by the Roentgen rays. [M. O.]

ZEITSCHRIFT FUER HEILKUNDE.

February 26, 1901. (28 Jahrgang, No. 8.)

1. Sensation in Peritoneum: Local and General Anesthesia in Abdominal Operations. K. G. LENNANDER.

1.—In resection of the bowel for gangrenous hernia, or in gastro-enterostomy, it has been the custom in Upsala, for 10 years, to stop administering anesthetics when the operator reaches the resection, or suturing of the intestine itself. Just enough was then given to prevent the patient from coming out of the influence of the anesthetic. Lennander has operated many times, for hernia, entero-anastomosis, fecal fistula, cholecystotomy, nephrostomy, etc., with Schleich's local anesthesia. From these operations he noticed that the parietal peritoneum showed great excitability to sensation of all kinds, while the peritoneum covering the abdominal viscera was absolutely insensible to stimuli. Especially was this marked with compresses; against the parietal peritoneum (of the anterior wall or sides), they caused great pain, but were not felt among the internal organs at all. The subserous tissue of the parietal peritoneum contains nerve-fibres, while that covering the viscera does not. In injecting cocaine by Schleich's method, both the serous and subserous tissues of the parietal peritoneum are made insensible. The pain in colic he explains as due to stretching of the nerves in the parietal peritoneum following distension of a part of the intestinal canal. Tenderness on pressure also will depend upon whether the parietal peritoneum is inflamed. From his own observations, Lennander concludes that in all abdominal operations without any suspicion of infection the Schleich method of anesthesia should be employed. If, for any reason, this should not be possible, a general anesthetic should be given until the main procedure is reached, when the anesthetic should be stopped. Or enough should be given just to keep the patient under. The result will be a painless operation, with only a small quantity of the anesthetic used. When local anesthesia is used, one person should attend solely to the patient, that he does not see or hear the instruments. [M. O.]

SCURVY IN INFANTS

By LOUIS STARR, M. D.

of Philadelphia

Infantile Scurvy is a constitutional disease occurring usually before the end of the second year, depending upon continued faulty feeding and presenting a well-defined complex of symptoms. The characteristic features are: First, immobility, progressing to pseudoparalysis, intense hyperesthesia, and general swelling situated most frequently in the legs, but not limited to these members; the investing skin is shiny and tense, but there is neither edema nor local heat, and subsidence of the general swelling reveals deep fusiform thickening about the shafts of the long bones in the neighborhood of the joints. In extreme cases there is a tendency to fracture near the epiphysis. Second, the gums about erupted teeth are swollen and purple in color, and, in marked cases, become spongy and readily bleed. Third, a rapid disappearance of all symptoms upon the institution of a proper, anti-scorbutic diet.

Scurvy shows no preference for sex, occurs at any season, in any climate or locality, amidst the best or worst hygienic surroundings, and in every class, though wealth furnishes by far the larger number of cases. In the majority of instances the disease develops between the age of six months and the end of the second year, though this limit is by no means a fixed one, and is closely confined to artificially fed infants, there being but two recorded cases in nurslings.

The direct causal factor is the continued use of food that lacks some essential nutritive elements or presents them in a form not readily assimilable. An analysis of the reported cases shows that the patients have received a great variety of foods, and if the few instances in which the only traceable cause is simple poverty in diet be eliminated, the sole factor that is uniformly present is the absence of the quality of *freshness*, the food is not "live." To put the whole question in a few words, the cause of scurvy in infants is *continued deprivation of fresh food*.

The faulty foods may be classed in the order of their potency:

1st.—The different proprietary infant's foods administered without the addition of cow's milk. These foods are responsible for the greatest number of cases, and which variety most readily induces the disease, depends chiefly upon the extent of employment or the fashion at the time.

2d.—Proprietary foods employed with the addition of insufficient quantities of cow's milk.

3rd.—Oat-meal or wheat gruel. Barley and other farinaceae administered with water alone or with water and insufficient cow's milk.

4th.—Condensed milk and water.

5th.—Sterilized milk. Properly modified milk mixtures subjected to a temperature of 212° F. from thirty minutes to an hour or more.

6th.—Too dilute milk and cream mixtures. Laboratory mixtures with too low albuminoid percentage.

Consideration of these groups furnishes an explanation of the greater frequency of scurvy in infants reared in luxury than in the very poor. The proprietary foods being expensive are little used by the latter class, the processes of modifying and sterilizing cow's milk are troublesome and require too much thought and time, and the cares of house work and bread-winning prevent regular and accurate artificial feeding. In consequence the child of poverty is fed upon milk, either diluted or pure, as the chance may be, and if this be not at hand, upon tea, potatoes, bits of bread or other table food; a bad diet, and one which often leads to rickets or dangerous gastro-intestinal disorders, but which is too varied and "live" to produce scurvy.

The variations in the diet usually made at the end of the second year, also explain the infrequency of the development of the disease after this age.

The essential cause of scurvy is unknown, but it is certain that it is some peculiar deprivation, and that the needed elements are present in fresh milk and the juice of fresh, ripe fruits.

Very few post-mortem examinations are on record, in fact, since infantile scurvy has been recognized as a distinct condition and its treatment established a favorable outcome is to be expected in the vast majority of instances. Of twenty-six cases that have come under my own observation during the past ten years, but one terminated fatally. This, my second diagnosed case, occurred in 1891.

The patient, a boy fifteen months old, had been ill nearly four months before I was consulted, and was so far reduced in flesh and general strength, was so anemic, and had such grave intestinal complications, that all efforts at treatment were unsuccessful. After death the body showed extreme emaciation, the skin was inelastic, pale, and presented numerous ecchymotic spots of varying size. The gums about the eight incisor teeth that had been cut were deep purple in color, very swollen and spongy and covered with blood. Both legs were much swollen above the ankle joints, the right to the greater extent. On section, the lower third of the right tibia was found to be surrounded beneath the periosteum, by a thick mass of dark, grumous blood, the lower epiphysis was detached, and the distal end of the shaft, macerated and eroded, lay free in the disintegrating blood clot. The lower third of the left tibia was surrounded by a similar, though less extensive, sub-periosteal blood effusion; it was not fractured. The fibulae, femora, and bones of the upper extremities were normal.

The intestines contained blood and blood-stained mucus, and the mucous membrane was thickened and studded, especially in the colon, with follicular ulcers.

Microscopic examination of the bone and periosteum showed no lesion beyond the mechanical one at the seat of fracture, and the same was true of sections from the liver, spleen and kidneys, and of the blood.

These findings correspond very closely to those detailed by Barlow and Northrup, and the anatomical lesions of the disease may be briefly stated to be chiefly due to hemorrhage, the most characteristic being the sub-periosteal blood effusions about the shafts of the femora and tibiae, sometimes of the long bones of the arms, and occasionally those of the cranium and thorax. Bleeding may also occur into the subcutaneous tissue (ecchymosis), and from the nose, stomach, bowels and bladder.

J. J. Thomas* asserts that the kidneys are frequently involved in infantile scurvy, and attributes the lesion, catarrhal nephritis, to the presence of an irritant in the blood, which, by its effects upon the walls of the renal vessels, produces hemorrhages. While this is a condition one would naturally expect, it was absent in my single fatal case, and in none of the others was either albumen or blood present in the urine during the course of the disease.

The scorbutic condition is produced gradually after weeks or months of improper feeding; there may be slowly increasing evidences of impaired nutrition before the characteristic symptoms appear, but usually these suddenly interrupt a state of apparent health. It is first noted that the infant is content only when perfectly quiescent; that he screams when lifted in the nurse's arms, or that he ceases to creep or walk. Soon it becomes evident that crying is produced most readily by movements involving the legs, and that either one or both limbs are held fixed, the thigh being drawn up towards the abdomen, the leg flexed, and the foot drooped. Next swelling appears above the knee or ankle joints, and immobility and tenderness increase; the latter to such an extent that the patient stops crying only while lying undisturbed on a pillow. Then the gums about any teeth that may be cut become purple in color; in the beginning there is merely a narrow line of this discoloration, but it rapidly extends; the gum swells, grows spongy, and bleeds at the lightest touch. With these special symptoms there is moderate general debility and loss of flesh, restless sleep, impaired appetite, a tendency to constipation, a diminished flow of high-colored, lateritious urine, and in some cases moderate elevation of temperature, though absence of fever is the rule.

Without treatment or when badly managed, the disease runs a chronic course, and the symptoms slowly but steadily increase in gravity, until emaciation becomes extreme, petechial spots appear on the surface, the swollen gums overlap the teeth, and there is a constant oozing of blood. The immobility, hyperesthesia and swelling affect the arms as well as the legs, epiphysal separation may take place, and the child, irritable and prostrated, lies passive upon the bed, dreading the slightest attempt at movement or even the approach of its nurse. The symptoms deserve a more detailed consideration in the order of their development.

Hyperesthesia is almost invariably the initial symptom, it appears in, and may be limited to one leg, but often involves both. The infant first exhibits sensation of pain by changes in facial expression or by crying when the affected member is

moved in changing the napkin or in arranging the stockings or dress. If the child be old enough to creep, stand or walk, it excites the mother's suspicion that something is wrong by suddenly becoming inactive, and by lamentations when induced to attempt previously enjoyed use of the legs. The tenderness increases steadily in degree, and, if primarily seated in one limb, extends to its fellow, and, in severe, long standing cases, to one or both arms; The little patient becomes helpless, suffers agony during the trifling movements necessary in making the toilet, and even anticipates pain and screams on the approach of the most gentle attendant. The characteristic of the pain is its production solely by movements of the parts involved, and if the element of dread can be eliminated, moderately firm pressure upon or friction of the surface is readily borne.

Immobility is the natural sequence of hyperesthesia, develops almost simultaneously, and with it increases in degree and extent. The decubitus is quite typical; the infant lies on its side with the trunk thrown a little forward, the thigh drawn half way up to the abdomen, the leg semi-flexed, and the foot drooped; when long maintained, this posture produces slight edema of the dorsum of the foot; this is not sufficient to show pitting on pressure, though the skin looks puffy and is shiny. When the upper extremities are affected, the forearm is semi-flexed and rests on the trunk. This posture is maintained for hours with no attempt at movement and no complaint while undisturbed.

The immobility is not paralytic in character, and if, despite the suffering produced, the limbs be manipulated, the joints are always found to be readily movable and free from stiffness.

Swelling of the soft tissues about the bones is a common feature; it varies in degree, though never very marked, and is quite distributed, spreading over the area of the bone affected; thus, when the femur is involved the tumefaction extends from the knee nearly to the hip-joint, when the tibia, from the ankle nearly to the knee; if the arm bones are affected, swelling while present is less noticeable. The swelling is greatest over the distal ends of the bones. It never involves the joints.

Any pressure that does not move the limb is painless; there is no pitting, the skin is normal in color, and there is no increased local heat.

As the case progresses the tumefaction subsides to a certain extent, tends to become limited to the lower third of the bone, and beneath it, deep pressure reveals a firm fusiform enlargement of the shaft; this is due to sub-periosteal hemorrhage and varies greatly in extent in different cases.

Lesions of the gums are observed only in cases in which one or more teeth have been cut; they appear early, but often escape attention until sufficiently far advanced for hemorrhage to take place. Primarily, the gum margin about the necks of the teeth becomes deep red in color and slightly swollen; soon the color changes to deep purple, the area of discoloration extends, the swelling increases, and ultimately the whole alveolar mucous membrane in the neighborhood of erupted teeth becomes ecchymotic, the swelling is so extreme that the thickened gum margin overlaps the teeth, the

*Boston M. & S. Journal, September 3rd, 1896.

tissue is spongy and hemorrhage is produced by the lightest touch or takes place spontaneously, blood constantly oozing in small quantities. Rarely sloughing occurs, and occasionally when the gum lesions are very marked, the teeth are temporarily loosened in their sockets; they should be maintained in position if possible, however, since they become firmly set again as the patient recovers.

The general features are very diverse in degree of prominence. Often, when the scurvy is mild in grade, the infant is seemingly so well nourished and in such apparent health, that the parents are surprised at the sudden development of local symptoms. Usually, however, even in these cases, the trained observer is able to detect evidences of malnutrition in the slight anemia and muscle flabbiness.

In well marked instances there is emaciation; dry, pale, or sallow skin; debility indicated by an irritable, weak pulse and loss of muscle tone; the tongue is lightly coated, the appetite capricious, and the bowels tend to constipation, the evacuations being rather scanty and clay colored, showing deficient biliary secretion. Occasionally there is diarrhea, with greenish mucoid discharges, and at times the feces contain blood. There may be more active indications of gastric indigestion, and very frequently there is an antecedent history of great difficulty in feeding on account of proneness to gastro-intestinal disturbance.

Fever is not a symptom of scurvy, and when present is due to some accidental complication, as intercurrent acute intestinal catarrh, and not to the disease itself. Under these circumstances, the temperature is generally but moderately elevated, the thermometer ranging from a little above normal to 100° or 101° F.

The urine is diminished in quantity, high colored, often laden with urates and increased in gravity. The frequent presence of albumen and the evidences of nephritis have been asserted, but is not borne out by my own experience. In grave cases there may be hematuria.

Hemorrhage is a late feature, appearing after prostration is advanced and the blood crisis has deteriorated. It takes place first in the sub-cutaneous areolar tissue, especially in dependent parts of the body, and beneath the mucous membrane of the mouth. The ecchymotic spots are deep purple in color, and range in size from that of a pin's head to patches one-fourth of an inch or more in diameter.

Bleeding from the gums has been already mentioned, and is an earlier symptom than sub-cutaneous ecchymosis. Later, epistaxis and hematuria may be observed, and, much more frequently, hemorrhage from the bowels, the leakage either merely staining the discharges from the rectum, or appearing as pure, though dark colored and altered blood. The loss of blood directly increases the cachetic condition noted in severe cases, and if at all profuse plays an important part in exhausting the vitality in fatal cases.

Fracture of the femur, tibia, or humerus, is a late symptom, and shows an extremely grave type of

affection. Separation at the lower third of the tibia existed in my single fatal case, and I know of no instance of recovery after its occurrence. In fact, it is doubtful if reunion of the soft macerated and eroded lower end of the shaft of the bone with its epiphysis, could be accomplished, even granting the possibility of the infant's recovery from the condition of extreme prostration and mal-nutrition that is invariably present before fracture takes place. The bone lesion gives rise to characteristic deformity; when the femur is involved, there is a distinct downward bend in the thigh, situated a short distance above the knee joint and due to weight traction of the part of the limb below the seat of separation; with the tibia, the same bending is observed above the ankle joint, but it is less in degree, because the fibula acts as a partial splint, and the depressing weight is not so great. Palpation does not yield crepitation, and it is difficult to feel the end of the bone through the surrounding soft tissues and the mass of extravasated blood.

As the greater number of scurvy cases are quite typical, the diagnosis is usually attended with little difficulty.

The distinguishing features are, the development in infants from six months to two years old, after the prolonged use of unsuitable food, of extreme hyperesthesia and immobility of the limbs; swelling of the thigh above the knee-joint and of the leg above the ankle-joint; fusiform enlargement of the lower third of the shaft of the femur and tibia; deep purple discoloration (ecchymosis), swelling and sponginess of, and hemorrhage from, the gums surrounding erupted teeth; general cachexia and anemia, and finally—the test feature—rapid disappearance of symptoms and complete recovery following the adoption of an antiscorbutic diet, and—the negative symptom—non-involvement of the joints.

The pain produced by movement and the immobility of the limbs are responsible for most of the errors in diagnosis, scurvy being frequently mistaken for rheumatism, hip-joint disease, paralysis and affections of the spine.

Considering the very uniform and characteristic complex of symptoms in scurvy, it is difficult to understand why this confusion should occur; but I have seen two cases in which a reputable surgeon had applied dressings for hip disease during a period of four and six weeks, and many in which counsel was requested, because a supposed rheumatic attack obstinately resisted every method of treatment. However, since the disease has been more carefully studied, illustrative cases reported, and the subject given a place in text-books, mistakes in diagnosis are becoming more and more infrequent.

The question of the relation of scurvy and rickets has been much discussed. Before the former disease had been carefully studied rickets was supposed to uniformly precede or accompany it, and prior to the publication of the observations of Cheadle and Barlow, it was classed as "acute rickets." Both diseases develop during infancy, and

both are caused by food that is deficient in certain essential qualities, but here the similarity ends. For the lesions of rickets are found in the bone tissue, those of scurvy in the blood vessels, and while the effects of these are readily and completely removable in scurvy, in rickets their mark is left permanently in bone thickening and deformity. Again alterations in diet that quickly terminate scurvy are inoperative in rickets. The two conditions, therefore, are not generically related; one may appear without the other, or they may co-exist in the same patient, though such an association is exceptional in my experience.

The symptoms of rickets show little similarity to those of scurvy and make the differentiation an easy matter. The most uniformly present and characteristic, in the type of cases in which there is the greatest likelihood of confusion, are profuse perspiration about the head and chest, anemia and evidences of malnutrition, delayed dentition, enlargement of the *joints*, bending of the long bones, cranio-tabes, misshapen head with prominence of frontal and parietal bones, rachitic rosary, deformity of thorax with depressed ribs and projecting, distorted sternum, and prominent abdomen.

Purpura may be distinguished from scurvy by its etiology, unsuitable food not being an essential cause; by the absence of hyperesthesia, immobility, spongy bleeding gums and deep sub-periosteal hemorrhage. The leakage of blood in purpura has a tendency to be general and more superficial, being most marked in the subcutaneous tissue and from the various mucous surfaces and kidneys.

When treatment is not guided by a correct diagnosis, scurvy runs a protracted course, and the patient gradually passes into a condition of such profound cachexia that death may take place from exhaustion. On the other hand prompt detection and judicious management almost certainly leads to rapid recovery, improvement beginning after a few days and all symptoms disappearing in from two to three weeks.

Dangerous symptoms are extreme anemia and prostration, epiphyseal separation, the appearance of petechial spots, the expulsion of blood from the bowels and hematuria. Extreme gastric irritability, making feeding difficult, and the intercurrent of enteric catarrh, materially add to the gravity of the prognosis.

The subjoined table of twenty-six cases, occurring in my own practice, is of interest as an illustration of the clinical features in infantile scurvy of the type ordinarily met with in practice.

The management of scurvy is very simple, depending entirely upon the substitution of a fresh antiscorbutic diet for whatever form of unsuitable food may have been the casual factor. If a proprietary food has been employed, it must be abandoned, sterilization must be discontinued as a process of preparation, condensed milk or food too rich in farinaceous material must be changed to a properly modified, untreated, cow's milk mixture, and if the food has been simply deficient in proteids, it

must be strengthened so far as the digestive powers admit, and any deficiency supplemented by the use of some other form of albuminoid, as raw-beef juice.

Briefly stated, the essential treatment is the employment of a food composed of cow's milk, cream, water, and milk-sugar, properly proportioned to the age of the infant, and given, so far as the cream and milk are concerned, in the natural, fresh state, i. e., not passed through the separator and not sterilized.

Pasteurization and predigestion at a temperature of 115° F., are admissible in certain cases, but should never be employed when the cream and milk are carefully handled at the dairy and can be kept clean and sweet, and when the infant's digestion is even moderately active.

The juice of fresh ripe fruit—orange juice especially—is a useful addition to the diet, and when, as is usually the case, it can be taken without producing diarrhoea, is an efficient aid to rapid recovery.

For scurvy in an infant of eight months, an appropriate food schedule is:

First meal, 7 A. M.

Cream.	½ ounce
Milk.	4½ ounces
Milk Sugar.	1 drachm
Water.	3 ounces

At 9 A. M.—One to two teaspoonsful of fresh orange juice, according to effect on bowels.

Second meal, 10.30 A. M. Same as first.

At 11.30 A. M.—Two teaspoonsful of raw-beef juice, free from fat, and with a little salt.

At 1 P. M.—One to two teaspoonsful of fresh orange juice.

Third meal, 2 P. M. Same as first.

At 3 P. M.—Two teaspoonsful of raw-beef juice with salt.

At 5 P. M.—One to two teaspoonsful of fresh orange juice.

Fourth meal, 6 P. M. Same as first.

At 8 P. M.—Two teaspoonsful of raw-beef juice with salt.

Fifth meal, 10 P. M. Same as first.

If orange juice cannot be obtained, or should it disagree, good substitutes are two to four table-spoonsful of scraped ripe apple (raw), two table-spoonsful of fresh grape juice, or six solid grapes from which the skins and seeds have been removed.

In addition to the alteration of the diet very little treatment is necessary. Gentle inunction of the limbs, with warm olive oil, may contribute to the comfort of the patient, and some acceptable preparation of iron, as the ferrated elixir of cinchona, will assist in restoring the strength and building up the blood. If there be great prostration, strychnia and alcoholic stimulants should be administered, and all complications must be met as they arise.

TABLE OF CASES OF INFANTILE SCURVY OCCURRING IN THE AUTHOR'S PRACTICE FROM 1890-1900.

Race Sex Class	Age	Prior Duration of Symptoms	SYMPTOMS	ETIOLOGY	Grade	TREATMENT	RESULT
White F. Wealthy	10 months	3 months	Swelling of both legs above ankle joints, immobility; hyperesthesia; Gums about the erupted teeth purple; swollen, spongy bleeding. Ecchymosis, slight at seat of swelling. Impaired digestion, tendency to constipation, marked emaciation, anemia and prostration; urine high colored, scanty. Temperature 100-101 F. No rickets.	Proprietary foods, then condensed milk mixture.	Severe	Home modified milk mixture (raw). Digestants and tonics (not sufficiently antiscorbutic, being my first case).	Recovery slow.
White M. Wealthy	10 months	4 months	Marked swelling of right leg with separation of epiphysis of tibia; moderate swelling at lower third left of leg and above both wrists. Immobility; hyperesthesia. Gums about the 6 erupted teeth extremely swollen, spongy, deep purple, sloughing, bleeding. Distributed petechiae, most numerous over swelling. Anorexia, tendency to vomiting and diarrhoea with blood-stained, mucoid evacuations; extreme emaciation, anemia and prostration; urine scanty but normal; temperature ranged from 99-102 F. No rickets.	Condensed milk from birth.	Fatal	Humanized milk. Beef juice. Iron. Codliver oil; stimulants.	Death after five months illness.
White F. Wealthy	5 months	3 months	Marked swelling above right ankle, less above left, considerable ecchymosis in these positions, immobility; great hyperesthesia, no teeth; gums normal; anorexia; irritable stomach; diarrhoea; emaciation; anemia; great prostration. Temperature range about 100 F. No rickets.	Artificial food from birth; condensed milk; proprietary food. Attack began while taking sterilized cows milk mixture.	Severe	Home modified milk mixture (raw), orange juice, raw beef juice, weeks. Restoration of general health slow, about 3 months.	Scurvy symptoms disappeared in 4 weeks. Restoration of general health slow, about 3 months.
White M. Moderate	7 months	3½ months	Great enlargement of lower third of right femur, skin over this region purplish; hyperesthesia; immobility. Emaciation and prostration marked; anorexia; occasional vomiting; tendency to diarrhoea with green, undigested evacuations; urine normal; no fever, no rickets. During treatment the lower incisors appeared, and the gums previously negative at once became purple and swollen.	Nursed one week, then fed upon strong oat-meal water with a little cows milk. Attack followed one month feeding on sterilized milk.	Severe	Humanized milk. Raw beef juice, digestants, stimulants, cod liver oil. Early use of diet not sufficiently antiscorbutic.)	Recovery progressive but slow, complete in three months.
White M. Moderate	8 months	3 weeks	Slight fusiform swelling at lower third of each thigh, and less above each ankle. Hyperesthesia, immobility, gums about 4 incisor teeth livid purple, very swollen and bleeding readily. Appetite fair, bowels regular, urine normal, slight pallor and muscular flabbiness, no emaciation, no fever, no rickets.	Artificially fed from birth properly proportioned cream and milk mixture, sterilized.	Mild	Sterilization discontinued.	Recovery in three weeks.
White M. Moderate	8 months	3 weeks	Swelling at lower third of each femur, and to less extent above ankle joints. Immobility; hyperesthesia. Gums about 4 incisor teeth purple, swollen and bleeding at slightest touch. Weakness, moderate anemia. Muscles flabby, no emaciation, Afebrile, no rickets.	Weaned at 6th week, then fed on a mixture weak in cows milk strong in a proprietary food.	Average	Cream and milk mixture, fresh and proper strength. Dr. 2 very mild weeks. Raw beef juice and dr. 1 orange juice 3 times daily.	Improvement after 10 days. Recovery in 2 weeks.
White F. Moderate	11 months	2 months	Considerable swelling above each knee joint less above the ankles. Hyperesthesia. Immobility. Dentition normally advanced, gums purple, swollen, bleeding. Anemia prostration, some emaciation, appetite poor, bowels constipated. Urine scanty but normal. No fever. No rickets.	Mixed feeding in early months. Weak condensed milk mixture. Attack followed severe epidemic influenza.	Average	Home modified cream and milk mixture. Raw orange juice. Raw beef juice.	Improvement in 10 days. Recovery in 2 weeks.
White F. Moderate	9 months	2 months	Swelling above both knees and ankles. Hyperesthesia. Immobility. 2 incisors cut, gums purple and swollen. Anorexia, impaired digestion, irregular bowels. Emaciation and prostration. No fever. No rickets.	Artificial feeding from birth. Sterilized weak milk mixture with proprietary food. Attack followed measles.	Mild	Cream and milk mixture. Sterilization stopped. Raw beef juice. Tonics.	Improvement in 7 days. Recovery in 4 weeks.
White F. Wealthy	8½ months	2 weeks	Hyperesthesia and immobility of both legs, but no swelling. 2 incisors cut, gums livid purple, much swollen. Irritable, no prostration or emaciation, some pallor. No symptoms of rickets.	Feed at breast for 1 month, then on condensed milk and a proprietary food.	Very mild	Cream and milk mixture. Raw orange juice. Raw beef juice.	Improvement in 7 days. Recovery in 2 weeks.
White M. Moderate	12 months	2 months	Hyperesthesia, immobility of both legs, and some swelling above the knee joints. 6 incisors cut, gums purple and swollen. Irritable, emaciated, anemic, anorexia, tendency to vomit, irregular bowels. No symptoms of rickets. Feeble from long continued malnutrition.	Artificial food after 1st week. 1st condensed milk then cows milk and cream mixture, sterilized.	Very mild	Pasteurization substituted for sterilization. Orange juice. Raw beef juice.	Immediate improvement. Recovery in 3 weeks.
White M. Moderate	15 months	3 weeks	Swelling above the knees and ankles. Hyperesthesia. Immobility. Dentition normally advanced, gums purple, swollen and readily bleeding. Marked anemia, emaciation and prostration. No symptoms of rickets.	Weaned at 4th month. Cows milk mixture to 7th month then and at time of onset a proprietary food.	Severe	Home modified cream and milk mixture. Raw orange juice. Raw beef juice.	Recovery in two weeks.
White F. Wealthy	8 months	6 weeks	Swelling of lower third of both legs. Hyperesthesia. Immobility of both legs and left arm, no swelling of latter. 2 incisors cut, gums purple and swollen. Anorexia, constipation. Anemia, muscle flabbiness and emaciation. No fever, no rickets.	Mixture of milk water and a proprietary food sterilized and predigested.	Average	Sterilization stopped. Humanized milk. Orange juice. Raw beef juice.	Improvement in 2 days. Recovery in 2 weeks.
White F. Wealthy	12 months	3 weeks	Swelling above the right knee and ankle. Hyperesthesia, immobility not complete. Upper and lower central incisors cut, lower gums show purple line, upper deep purple and swollen. Anorexia, constipation, moderate pallor, weakness and emaciation. Urine scanty. No fever, no rickets.	Artificially fed from birth on proprietary food.	Mild	Partially predigested cream and milk mixture. Orange juice and raw beef juice.	Recovery in two weeks.

TABLE OF CASES OF INFANTILE SCURVY OCCURRING IN THE AUTHOR'S PRACTICE FROM 1899-1900.

Race Sex Class	Age	Prior Duration of Symptoms	SYMPTOMS	ETIOLOGY	Grade	TREATMENT	RESULT.
White M. Wealthy	15 months	6 weeks	Scurvy followed prolonged illness. Chronic enterocolitis, bronchitis, mastoid disease. Hyperesthesia and immobility of left leg 10. Teeth cut, gums deep purple, much swollen, readily bleeding. No symptoms of rickets.	Long continued illness. Food on account of impaired digestion, too low in albuminoid percentage.	Mild	Added to dilute milk mixture, mashed potatoes, dry bread and seaweed fruit. Raw beef juice.	Recovery rapid.
White M. Wealthy	13 months	6 weeks	Swelling above both knee joints. Hyperesthesia. Immobility. Dentition normally advanced, gums purple, swollen, bleeding, teeth loose. Marked emaciation, prostration and anemia. Temperature ranged from 98.4° to 103° F. No rickets.	Condensed milk feeding from birth	Severe	Home modified cows milk mixture (raw). Orange juice. Raw beef juice.	Recovery in about 3 weeks.
White M. Wealthy	15 months	3 months	Child feeble from birth, difficult to feed, and badly fed and managed. Swelling of both legs above ankles. Hyperesthesia. Immobility. Dentition normal, gums purple. Extremely swollen, bleeding. Anorexia, feeble digestion, obstinate diarrhoea with fetid discharges. Emaciation, anemia, prostration. Fever moderate. No rickets.	Persistent bad feeding.	Severe	Egg-albumin, water and raw beef juice, child gradually built up to broths and milk mixtures, stimulants, health slow, complicating diarrhoea treated.	Active scorbutic symptoms disappeared in 2 weeks, but restoration to health slow.
White F. Wealthy	10 months	3 months	Swelling of lower third of right femur and lower third of right leg. Hyperesthesia. Immobility. Dentition normal, gums purple, swollen. Moderate pallor, weakness and emaciation. Anorexia, constipation. No fever and no rickets.	Artificially fed from birth. Food too low in albuminoid percentage.	Mild	Home modified milk mixture (raw). Orange juice. Raw beef juice.	Recovery in about 4 weeks.
White M. Wealthy	15 months	6 weeks	Marked fusiform enlargement of lower third of right femur. Hyperesthesia. Immobility. Dentition normally advanced, gums purple, very swollen, readily bleeding. Anorexia, constipation. Emaciation, anemia. Weakness. Urine scanty, high colored. No fever. No rickets.	Artificially fed from birth. Weak cows milk mixture with a proprietary food.	Severe	Home modified milk mixture (raw). Orange juice. Raw beef juice.	Improvement noticed in 2 days. Recovery complete in 18 days.
White F. Moderate	15 months	3 months	Swelling of both tibiae above ankle joint, right most marked; slight swelling of both arms above the wrists. Hyperesthesia. Immobility of legs complete, of arms partial. 7 teeth cut, gums purple, swollen, bleeding; first molars in upper jaw nearly erupted investing gums, swollen and purple. Anorexia, constipation, poor digestion, prostration, great emaciation. Urine scanty, high colored. No fever. No rickets.	Weaned at 2nd month, then fed on sterilized milk (long process), and then on sterilized milk alternating with a proprietary food.	Very Severe	Home modified milk mixture predigested with peptogenic milk powder at 115° for 4 minutes. Orange juice, raw beef juice.	Improvement at once. Recovery in 2 weeks.
White M. Moderate	13 months	3 months	Hyperesthesia and immobility of legs; no swelling, 8 teeth cut, gums purple, greatly swollen, readily bleeding. Appetite poor. Irregular bowels tending to constipation. Marked anemia and emaciation. No fever. No rickets.	Bottle fed from birth; milk mixture, properly proportioned, but sterilized (long process).	Mild	Sterilization discontinued.	Improvement immediate. Recovery in 3 weeks.
White F. Moderate	10 months	6 weeks	Hyperesthesia and immobility of both legs, some swelling above knees. 6 teeth cut, gums purple, slightly swollen, anemia, poor appetite, regurgitated a portion of each feeding. Obstinate constipation. No fever, no rickets.	Bottle fed from birth, food too dilute.	Very Mild	Home modified milk mixture (raw). Orange juice, raw beef juice. Laxative Suppositories.	Improvement immediate, recovery in 10 days.
White M. Moderate	14 months	2 weeks	Hyperesthesia and immobility of both legs, no swelling about bones. 6 teeth cut, gums purple and moderately swollen; poor appetite, impaired digestion, constipation, anemia, moderate prostration, little emaciation. No fever. No rickets.	Breast fed for 2 months, then on varying foods, condensed milk and several proprietary foods.	Very Mild	Home modified milk mixture (raw). Orange juice, raw beef juice.	Recovery rapid.
White M. Moderate	12 months	2 weeks	Some swelling above left ankle, both legs hyperesthetic and immobile. 6 teeth cut, gums purple and much swollen, anemia, muscle flabbiness, anorexia, emaciation, irregular bowels with undigested evacuations. Temperature 98.5° to 101° F, urine normal. No rickets.	Artificially fed from birth to 7 months. No milk diet 3 weeks, but nursed from seven weeks breast. Proprietary food.	Average	Home modified milk mixture (raw). Orange juice, raw beef juice.	Marked improvement in 3 days, recovery in 3 weeks.
White M. Wealthy	14 months	6 weeks	Fusiform swelling above both ankle joints. Hyperesthesia. Immobility. No swelling but hyperesthesia and partial immobility of left arm. 10 teeth cut, gums deep purple, very swollen, readily bleeding. Appetite normal, bowels tend to constipation. Urine high colored, emaciation, anemia, some prostration. No fever. No rickets.	Breast fed for 3 months; then proprietary foods.	Average	Home modified milk mixture (raw). Orange juice.	Recovery in two weeks.
White M. Moderate	9 months	4 weeks	Fusiform swelling above left ankle joint, with legs hyperesthetic and immobile. 6 teeth cut, gums deep purple, greatly swollen and bleeding, anemia, constipation, urine scanty but normal, emaciation, weakness. No fever. No rickets.	Artificial feeding from birth, too weak milk mixture.	Mild	Home modified milk mixture (raw). Orange juice.	Recovery rapid.
White F. Wealthy	10 months	1 week	No swelling, but hyperesthesia and immobility of both legs. One lower incisor cut, gums purple and slightly swollen. Constipation, pallor and muscle flabbiness, but general nutrition good. No fever. No rickets.	Artificially fed from birth. Laboratory milk fat 4 sugar 7 albuminoids . . 1	Very Mild	Home modified milk mixture (raw). Orange juice.	Recovery in one week.

NOTES ON LEUKEMIA WITH A REPORT OF THREE
CASES.*

By CHARLES S. JEWETT, Ph. B., M. D.

of Buffalo, N. Y.

Visiting Physician to the Erie County Hospital. Clinical Pathologist to the Buffalo Hospital of the Sisters of Charity.

In November, 1845, Virchow (1) published his first description of a case in which the white cells of the blood were enormously increased both absolutely and relatively to the red cells. In 1846 (2) he reviewed his own and three other published cases, insisting that the increase of white cells was not due to pus, and hence that the condition was not a suppuration of the blood. In January, 1847 (3) he cited further cases from the literature, one (of Bichat) dating back to 1801, and discussed the relation of the spleen to the white cells. Later in the same year Virchow proposed the name leukemia—white blood. In October, 1845, Craigie and Bennett (5), of Edinburgh, published a case of great increase of the white cells of the blood which they believed to be due to the presence of pus, and hence termed suppuration of the blood. In 1851 Bennett (6) published further cases and proposed the name leucocythemia—white-celled blood. Bennett's claim to priority based upon his first paper has been generally disallowed, and it now seems clear that Virchow was the first to recognize the essential nature of the disease, the fact that it is not a suppuration, and to discover the relationship between the leukemic alterations in the blood and certain pathological changes in the spleen and lymph nodes. The first case diagnosed during life was that of Vogel (7) in 1849. Virchow recognized two forms of the disease, the splenic and the lymphatic, while it was reserved for Neumann (8) in 1869 to describe the participation of the bone marrow in the leukemic process, and to establish the myelogenous form of leukemia. During the past thirty years leukemia has received much attention from clinicians and hematologists, and also from the standpoint of pathological anatomy, and the literature of the subject is enormous. It is not the object of this paper to review all the various theories regarding the nature and classification of this disease, but rather to summarize our present views regarding these points.

As to the nature of leukemia, three chief theories have been and are held, of which Taylor (9), in Sajous's Cyclopedic, gives the following summary: "The Virchow-Neumann theory considered the excess of white corpuscles to be due to an abnormal hyperplasia of the hematopoietic tissues, and most of the adherents of this view have conceived this hyperplasia as analogous to that seen in malignant neoplasms." "The Bisiadecki-Loewit theory predicates a retardation of the evolution and prolongation of the life of the circulating leukocytes, the collections in the tissues being interpreted as the results of the deposition of the excess of the circulating leukocytes." This theory to-day finds few adherents. The modern theory is "that leukemia is an infection, and that the hyperplasia of the lymphatic tissues and the circulatory excess of white

cells are the result of a specific stimulation and leukocytosis analogous to those seen in other infections." This third theory, whether accepted for all cases or only for certain forms of leukemia may be regarded as an elaboration and explanation of the Virchow-Neumann theory, agreeing with it in regarding the blood changes as secondary to the lesions of the fixed tissues while expanding it by attempting to show the cause of these latter lesions. To-day the infection-theory is the one most generally accepted for the acute leukemias, while it is by no means impossible that all forms of leukemia may be caused by one or more infective agents. So far all efforts to demonstrate the specific organism have been disappointing. The various bacterial forms which have been found in leukemic blood were probably all due to complicating infections or to post-mortem contamination. Loewit has thus far failed to offer convincing evidence that the sporozoa described by him stand in a causative relation to leukemia or even that they are anything more than the products of cellular disintegration. Nevertheless, while we lack the demonstration of a specific infective agent, the argument from analogy is so strong that it is difficult to doubt the infectious nature at least of the acute forms of leukemia. The classification of the various forms of leukemia has caused much confusion in the past, but most of the later writers seem to be reaching a substantial agreement which harmonizes the pathological and the morphological classifications. Ehrlich and Lazarus (11), Cabot (12), Osler (13), and Von Limbeck (14), agree in dividing leukemia into a lymphatic and a spleno-myelogenous or myelocytic form, while Engel (15) adds a splenic leukemia and Taylor (9) a mixed form. Engel says that in splenic leukemia the polynuclear neutrophiles predominate, but admits that these cells originate in the bone marrow and are adult forms of the myelocytes, while he makes no distinction between this condition and neutrophilic leukocytosis, except the permanence of the former. Taylor's (9) mixed form is said to include the whole group of acute leukemias, but in describing it he quotes Fraenkel as saying:—"The blood changes are entirely characteristic. There is a remarkable increase of the mononuclear elements, which are of the most varying sizes, but do not contain neutrophilic granules." Obviously, such a form would ordinarily be classified as lymphatic and would thus be brought into harmony with the more usually accepted classification. Von Jaksch (16) recognizes a splenic form, although he admits that, at the autopsy in almost any case, leukemic changes more or less marked will be found in spleen, marrow and lymph nodes. His description of the splenic form is "one in which simply relatively large leukocytes are found." Judging this rather vague description from the context, it would seem to refer to what others call a lymphemia, in which the larger forms of lymphocytes predominate. It is thus not difficult to bring these seeming variations into harmony with the classification which we have adopted of myelogenous and lymphatic leukemia. While these two forms may usually be readily distinguished, it is necessary to recognize that a mixed form does occur, though rarely. Though splenic tumor is a constant feature

*Read before the Pathological Section of the Buffalo Academy of Medicine, February 19, 1901.

of the myelogenous form, it is also a most common accompaniment of lymphemia, and Neumann (17) early pointed out that lymphatic overgrowth is not necessarily confined to the lymph nodes, but may involve the spleen or the bone marrow itself. Inasmuch as we know of no special forms of white blood cells furnished by the spleen, and as we have no pathological records of pure splenic leukemia, there seems to be no reason for recognizing this as a separate class, and when, in this paper, the word splenic is used in speaking of any case, it should be understood as referring to the splenic tumor and not to any peculiarity in the blood composition. A further classification of leukemia is into an acute and a chronic form. As the acute cases are almost invariably, if not always, of the lymphatic variety, it is usual to sub-divide lymphemia into two forms, acute and chronic. The diagnosis of leukemia can be satisfactorily made only by means of a microscopical examination of the blood. The question, however, whether by means of the blood examination alone it is possible to determine the presence or absence of leukemia, and whether by studying stained blood preparations we can decide upon the form of leukemia, which is present, are still under discussion; but the present tendency is to answer both in the affirmative. Bearing in mind that the characteristic blood changes of leukemia are qualitative rather than quantitative, the truth seems to be that, in any well marked case, it is possible from the blood examination alone to determine both the existence of the disease and its variety. In the earliest stages this result may not be obtainable, and it must be admitted that certain well-developed cases show during their progress, as a result of complications or of therapeutic measures, such marked remissions in the leukemic peculiarities of the blood composition that an examination during one of these remissions would necessarily fail to show the true character of the disease. In such cases repeated blood examinations may be necessary in order to clear up the diagnosis.

In myelocytthemia or splenic-myelogenous leukemia, the characteristics of the stained specimen of blood are, according to Ehrlich and Lazarus (11), as follows:—

"A. That aside from the polynuclear cells the mononuclear granular leucocytes also appear in the circulating blood.

B. That in the increase of the white blood cells all three types of granular cells, the neutrophiles, the eosinophiles and the *Mastzellen* participate.

C. That atypical forms appear, for example, dwarf forms of the various sorts of white blood cells, also mitotic or karyokinetic figures.

D. That the blood always contains nucleated red blood cells in large numbers."

Ehrlich and Lazarus (11) lay special stress upon the fact that no one variety of cell is pathognomonic of this disease, and it is through a misunderstanding of Ehrlich's position in regard to this matter that much controversy has arisen. The predominant characteristic of the blood picture in this form of leukemia, is the presence of large numbers of myelocytes, or large mononuclear leukocytes containing neutrophilic granulations. These cells are never found in the circulating blood in health, and

although occasionally seen in other diseases, for example, diphtheria, pneumonia, severe anemias, lympho-sarcoma and various children's diseases, still in none of these is their number to be compared with the numbers found in even the least marked cases of myelogenous leukemia. Mononuclear eosinophiles are found in small numbers. Normally, these varieties of white cells are found only in the bone marrow, and they are regarded as the direct antecedents of the corresponding polynuclear cells. The polynuclear eosinophiles always show an absolute, and often a relative increase. This point has, however, lost much of its diagnostic value, since the discovery of an eosinophilic leukocytosis. The appearance of atypical forms of all the varieties of leukocytes, and of cells, which are difficult to classify in any way, is highly characteristic of the disease under discussion, and gives to the blood picture a most variegated appearance. Nucleated red cells—both normoblasts and megaloblasts—are always found in large numbers, but no such preponderance of megaloblasts is seen as that which characterizes the blood of pernicious anemia. Often in the early stages no anemia is found, and later in the disease the anemia is usually moderate in degree, so that the number of nucleated red cells is far greater than in anemia of like grade, due to other causes. We see, then, that the blood in myelogenous leukemia presents a most characteristic picture, differing in almost every point from normal blood.

In lymphatic leukemia the picture is quite different, but hardly less distinctive. Here the number of leukocytes is ordinarily much less than in the myelogenous form, while the anemia is usually far more pronounced, especially in the acute and sub-acute cases. The typical feature is the great absolute and relative increase in the number of lymphocytes—mononuclear leukocytes with non-granular protoplasm. Neutrophiles, eosinophiles and myelocytes are comparatively rare. The nucleated red cells are far more numerous than in myelocytthemia, their number corresponding fairly well to the degree of anemia present, except in children, in whose blood the nucleated reds may be present in very considerable numbers. While leukemia ranks as a comparatively rare disease in this country, it is not unlikely that many cases are overlooked. During the past year it has been my fortune to see and examine three cases which I desire here to report. These cases occurred in the practices of Dr. Eugene Wasdin, Marine Hospital Surgeon; Dr. Marcel Hartwig, and Dr. Charles R. Borzilleri, and to the courtesy of these gentlemen I am indebted for the opportunity of making this report:

CASE 1.—C. S., aged 36, German, single, a boat steward. In 1882 he lived at Santos, Argentina, for 6 months, and from there shipped for Liverpool. On this voyage eleven of the crew died of yellow fever, and six escaped infection. In 1886 he was in Brunswick, Georgia, for six months, where his general health became so poor that he was unable to do his work. He finally left on the advice of a physician. In 1895 he conducted a bakery beside the Chicago drainage canal, which was then in process of construction. The water supply was contaminated with drainage. Diarrhea, dysentery and malaria were common in the camp. Here he suffered from severe headaches, diarrhea and great prostration for five months. He then went to Duluth, where he speedily recovered from these

symptoms. In the spring of 1896 he first noticed a swelling in the left side. The tumor was diagnosed as splenic, and within six months attained about its present size. He has taken Fowler's solution for the past three years. On May 4th, 1900, he entered the Marine Ward of the Buffalo Hospital of the Sisters of Charity, complaining of diarrhea. Marked tenderness was found over the sternum and tibias, and a splenic tumor was found, the limitations of which were as follows:—

From the navel toward the right	5 inches.
" " " " left	11 inches
" " " upward	7 "
" " " downward	6 "

A blood examination made by me two days later gave the following results:—

Hemoglobin.	50% von Fleischl
Leukocytes.	272,000 per c.m.m.
Erythrocytes.	3,630,000 per c.m.m.
Ratio of white to red cells, 1:13.3.	
Differential count of leukocytes:—	
Lymphocytes (small)	08%
Large monocuclear leukocytes and transitional forms.	2.5%
Polymorphonuclear neutrophiles	39.6%
Eosinophiles.	6.4%
Mast cells.	1.3%
Myelocytes.	49.3%
Eosinophilic myelocytes.	0.1%

Nucleated red cells:—In counting 1000 leukocytes there were seen 30 normoblasts and 14 megaloblasts. The nuclei of several of these cells showed a tendency to subdivide and one megaloblast was seen in which the nucleus was completely divided into two equal parts. The red cells showed poikilocytosis with macrocytes and microcytes and a few showed polychromatophilic degeneration. Atypical forms of leukocytes which are difficult to classify were seen in large numbers. The entire blood picture was characteristic of a high grade of myelogenous leukemia. The urine showed no abnormality except a moderate increase of indican. The patient was discharged from the hospital May 19th, 1900, unimproved.

CASE 2.—P. B., male, age 13 months: The elder of twins and from birth the smaller and weaker. The family history is negative, father, mother and twin brother are living and in good health. The child was never robust, but his illness dated only from March, 1900, and was characterized by severe anemia, feebleness, occasional diarrhea and malnutrition. Beginning in April there was slight irregular fever. In May a tumor was first observed in the left side of the abdomen. There was at no time any visible or palpable enlargement of the superficial lymph nodes, nor were there any hemorrhages observed.

I saw this patient June 1st, 1900, and found the child moderately emaciated, with enlarged abdomen and with a profound pallor. The spleen was easily palpable and extended downward to the level of the umbilicus. Its edge was parallel to the free border of the left ribs and from 1½ to 2 inches from it. The blood examination gave the following results:—

Hemoglobin.	30% von Fleischl
Leukocytes, 21,600 per c.m.m.	
Erythrocytes, 1,912,000 per c.m.m.	
Ratio of whites to reds, 1:91.	
Differential count of leukocytes:—	
Lymphocytes, large and small	87.0%
Polymorphonuclear neutrophiles.	10.5%
Eosinophiles.	1.5%
Myelocytes.	1.0%

In counting 200 leukocytes there were seen 8 normoblasts and 8 megaloblasts. The blood picture is striking through the great predominance of lymphocytes, showing all gradations from small to very large, many of them staining poorly both in nucleus and protoplasm. The large forms are very numerous, but the presence of all intermediate sizes renders the subdivision into two groups impracticable. The great diminution in the percentage of neutrophiles is very striking. The red cells show a marked poikilocytosis. Microcytes and macrocytes are numerous, as well as all manner of irregular forms. Polychromatophilic degeneration is well marked. Diagnosis:

subacute lymphatic leukemia. This patient died 17 days later. No autopsy was held.

CASE 3.—X., female, age 7 months. Family history:—Father and mother, aged respectively 39 and 30, both born in Italy, are living and in good health. Of twelve uncles and aunts nine are alive and well. The causes of death in the other three unknown. No specific history. Oldest brother, sound and well until five months old, when he developed enlargement of the abdomen, great anemia and emaciation. These conditions continued until the eleventh month, when he died. Second brother, died at three months of bronchitis. Third brother, developed gangrene of both lower extremities at the eleventh day, which gradually extended upward until his death on the twenty-first day. Sister, well until four months old, when she developed marked anemia, splenic tumor and emaciation, and died at the eighth month. Fourth brother, except for some of the ordinary infectious diseases of children, has always been well, and is so now at the age of four years. Case number three, the sixth child in this family was apparently well until four months old. He then developed anemia, which became profound, enlargement of the spleen, emaciation, troublesome diarrhea, slight irregular fever and great debility. There was noticeable enlargement of the superficial lymph-nodes in the cervical and axillary regions. No history of hemorrhages. At the age of seven months, July 16th, 1900, I examined the blood of this patient with the following results:—

Hemoglobin.	25% von Fleischl
Leukocytes, 33,000 per c.m.m.	
Erythrocytes, 1,150,000 per c.m.m.	
Ratio of white to red cells, 1:35.	
Differential count of leukocytes:—	
Large and small lymphocytes.	78.6%
Polymorphonuclear neutrophiles.	18.2%
Eosinophiles.	1.8%
Myelocytes.	1.4%

In counting 500 leukocytes 14 nucleated red cells were seen, all normoblasts, and one of them showing mitotic division of the nucleus. The other characteristics of the stained specimen were essentially similar to those seen in Case 2, the most noticeable difference being the absence of megaloblasts. Diagnosis:—Subacute lymphatic leukemia. The patient died about one month after this examination. No autopsy was held.

In cases 2 and 3 it will be noted that the absolute numbers of leukocytes were not sufficiently high to exclude a leucocytosis and a study of the morphology of the white cells was necessary in order to arrive at a diagnosis. Case number 3 is further interesting, because it seems highly probable from the history that a brother and a sister of this child also died from leukemia.

In conclusion, a few words as to the diagnosis of cases 2 and 3. It may be urged that these should be regarded as examples of the anemia infantum pseudo-leukemica of von Jaksch. Without entering into the controversy as to whether or not we are justified in regarding the group of rather widely varying cases which have been classified under this title as examples of a distinct disease, I would say that I am inclined to agree with von Limbeck (14), Schmaltz (18), Epstein (19), Raudnitz (19), Fischl (19), and Cabot (12), in questioning the existence of anemia infantum pseudoleukemica as a definite entity.

My two cases, moreover, differ from von Jaksch's description of this disease in at least the following points:—

a. Neither the number of red cells nor the amount of hemoglobin is reduced below the findings in well authenticated cases of leukemia.

b. Extraordinarily large neutrophiles are not found.

c. No white cells have been found which contain red cells or portions of red cells within their protoplasm.

d. The great majority of the leukocytes are lymphocytes and not polymorphonuclear neutrophils.

While recognizing the frequency of splenic tumor, of an increased percentage of lymphocytes and of the appearance of numerous nucleated red blood cells in the severe anemias of infancy, and while regretting the absence of autopsies in these two cases, still, in view of the very great preponderance of lymphocytes, and of the absence of all evidence of tuberculosis, syphilis, rachitis, or other cause of secondary anemia, I feel justified in classifying both cases as instances of true lymphatic leukemia.

CLINICAL EXPERIENCE WITH ADRENALIN.*

By EMIL MAYER, M. D.

of New York City

Surgeon New York Eye and Ear Infirmary, Third Department, Pollock American Laryngological Association of the New York Academy of Medicine, Etc.

The aqueous extract of the suprarenal glands is, perhaps, the best culture medium known. Its instability, the involved method of preparation, its unsightliness, and finally the inexactitude of its various strengths, all tend to make us welcome a preparation which shall be exact, stable, and, above all, clean.

Chemists of repute have been laboring unceasingly in the attempt to isolate the active principle, and in 1897 Prof. J. J. Abel, of Johns Hopkins University, announced that he had succeeded in isolating the blood-pressure-raising constituent of the suprarenal gland, which he named Epinephrin. Some time after Dr. Otto von Furth of Strasburg, declared, in the *Zeitschrift für Physiologische Chemie* (Vol. XXIX, p. 106), February, 1900, that Epinephrin was merely impurities mixed with the active principle, and claimed that he had isolated the real active principle, which he named Suprarenin.

In a recent communication (*American Journal of Physiology*, March, 1901), Prof. Abel says that Suprarenin is only a modification of Epinephrin.

Believing that neither Prof. Abel, nor Dr. Furth had obtained the active principle in pure isolated form, Dr. Jokichi Takamine, now of New York city, recently undertook the task of isolating the active principle of the suprarenal gland, and stated that he had been successful in isolating the blood-pressure-raising principle of the gland in a stable and pure crystalline form. His methods were entirely different from those of either Abel or Furth, and not wishing to usurp the credit due to previous investigators, he named his product Adrenalin.

The following is a description of Adrenalin and its physiological effect: "Adrenalin is a light, white, micro-crystalline substance, showing itself thus far in five different forms of crystals, according to the different condition of solutions from which they have been made. In fact, a given quantity can be transformed from one shape of crystal to another by a different method of crystallization. The five different ones are: (1) wart, or tomato-like; (2) boat, or leaf-shaped; (3) rhombic plates and their agglomerations; (4) fine needles; (5) prism-shaped. Adrenalin has a slightly bitterish taste, leaving a numbed feeling on the spot of the tongue where it has been applied. When dry it is perfectly stable. On heating it turns brown at 205° C., and melts, decomposes and swells simultaneously at 207° C. Adrenalin shows slightly alkaline reaction on moistened litmus paper. Phenol-phthalein also indicates slight alkalinity. It is soluble in cold water with difficulty, and more readily in hot water. The hot saturated aqueous solution separates the crystal after cooling. The colorless aqueous solution of Adrenalin is easily oxidized by air, changing its color from pink to red and eventually to brown. It is easily soluble in acids or alkalies, but not in ammonia or alkaline carbonates.

"Three kinds of salts, Hydrochloride, Sulphates, and Benzoates were made, by carefully dissolving Adrenalin with three different acids and evaporating *in vacuo* over strong sulphuric acid. In course of time they became a brown brittle amorphous mass, deliquescent in the air. So far efforts to crystallize them have failed. Experiments were made and showed that the physiological activity of Adrenalin was astoundingly strong. A fraction of one drop of aqueous solution of Adrenalin or its salt, in the strength of 1 to 10,000, blanches the normal conjunctiva within 30 to 60 seconds. It is a powerful astringent.

"Intravenous injection produces a powerful action upon the muscular system in general, but especially upon the muscular walls of the blood vessels and of the heart, resulting in enormous rise of blood-pressure.

"A comparative test of the strength of Adrenalin with the fresh extract of suprarenal gland, 1 cc. of which represents 1 gramme of fresh gland, was carried out on a dog weighing 7 kilos. Adrenalin solution corresponding to 0.000008 gm., was intravenously injected, and the rise of blood-pressure was 14 mm. of mercury. In order to have an equal amount of rise in blood-pressure, 0.005 gm. of the suprarenal extract was necessary.

"These data show that Adrenalin is 625 times

*Read before the Section of Laryngology of the New York Academy of Medicine, March 27th, 1901.

stronger than suprarenal extract. The sample of Adrenalin used for this experiment contained some mineral impurities, and pure Adrenalin will be over 1000 times stronger than the fresh gland.

"Approximately 1-200,000 grammes of Adrenalin intravenously injected into an adult man is sufficient to produce some distinct effect."

A small quantity of the solution of Adrenalin chloride, 1 to 5,000 in normal salt solution, was placed in my hands in December, 1900, through the courtesy of Dr. W. H. Bates. The liquid was colorless, odorless and slightly salt to the taste. By an accident the fluid was lost, but early in the present year several bottles of varied strengths of this solution, 1 to 1,000, 1 to 5,000, and 1 to 10,000, together with a bottle of the crystals of Adrenalin, were placed in my hands for experimentation, through the courtesy of Dr. Takamine. The cases in which these were applied were all rhinological, and it is to their effect in these conditions only that my remarks apply. The blanching of tissues following the application of the strongest of these solutions was accompanied within a few seconds and was very thorough. It was less extensive and a trifle slower as the weaker solution was applied. In no instance was there any constitutional disturbance following its use. Since these investigations began no suprarenal extract has been employed by me for any purpose whatever. The solutions were in colored glass bottles, with glass stoppers, and slowly changed in color, becoming pink, brown and finally muddy, and floccules, such as are noticed in cocain and morphia solutions, appeared. The effect of the remedy was not altered by these changes, and the same bottles and their contents were constantly employed for six weeks. Subsequently a small amount of chloretone was added to the fresh solutions, and now there is but slight change of color and no floccules appear. The specimen of this latter solution here presented has been in daily use for a month from the same bottle, and it will be seen to be clear and slightly yellow in color. Tablets of Adrenalin tartrate have been made which are readily soluble in water,; one dissolved in 16 grammes of water makes a solution of 1 to 1,000. These tablets are so prepared that their solution remains unchanged when dissolved. Still smaller tablets are to be had, and one of these latter, when dissolved in enough water to fill the ordinary atomizer bottle, will be all sufficient for the patient's use. It is needless to say that this form of the tablet will be most convenient. The thirty-five cases in which this active principle was applied are taken from my case book from among my private patients, and from notes made at my clinic. They are here briefly tabulated: The tables presented show at a glance that the usual effect of the aqueous extract of the suprarenal gland was obtained. A few operative cases bled freely, a fact that occurs occasionally with the extract itself, but in every instance the hemorrhage was promptly checked by a second application of Adrenalin. Following my previous experience with the suprare-

nals, in which subsequent hemorrhage occasionally occurred, every case operated upon, except two, were packed after operation with iodoform gauze and the dressing left in situ for 24 hours. No hemorrhage occurred in these cases. In the two cases the patients' noses were not packed, but they were placed in bed and kept quiet, for two days and Adrenalin 1 to 10,000 was applied by means of spray every two hours. There was no subsequent hemorrhage in either of these cases.

It is worthy of note that following the use of suprarenal extract and also of Adrenalin, a slough occasionally forms just as occurs in cautery operations on the mucous membranes. This has occurred in quite a number of cases, both post-operative and in merely inflammatory states, and probably tends to protract the subsequent healing. This effect may be useful to us in some of our operative work on the nasal mucosa.*

It will be seen that not only was the Adrenalin used as a hemostatic, but for the relief of nasal congestion, as a diagnostic aid, and for the continuous treatment of acute inflammatory affections of the accessory sinuses. It was of this latter effect of the suprarenals that I wrote to Bates some months ago, that if that remedy had no other uses, its value in giving prompt relief in acute vaso-motor rhinitis was so enormous as to place it in the front rank in nasal therapeutics.

The following conclusions seem justifiable as a result of personal experience with the active principle of the suprarenal gland in these cases:—

1. Adrenalin solutions supply every indication in rhinological practice for which the aqueous solutions of the extract have been hitherto applied.
2. They can be used in sterile form.
3. They remain unchanged for a long time.
4. A solution of 1 to 1,000 is very strong and is all sufficient for operative cases, and 1 to 5,000 or 1 to 10,000 for every purpose of local medication.
5. They may be safely applied to persons of every age and of either sex.

My own experience having been so highly satisfactory with Adrenalin, makes me feel justified in saying that in the isolation of the blood-pressure-raising principle of the suprarenal glands we are confronting an epoch-making discovery. The discovery of the active principles of other animal substances will be sure to follow in the near future and organo-therapy will not only derive a new impetus, but exactitude in the administration of these remedies will be sure to follow.

We will no longer be compelled to use an animal extract of potency to-day, and an utterly inert one at another occasion, but would always have the same remedy of known strength and power. Percentages of solutions would be exact in every instance, and in appropriate cases their administration by hypodermic methods could safely be employed with absolutely sterile solutions.

TABULAR CONSPECTUS OF THE APPLICATION OF ADRENALIN.

Case No.	Age	Sex	Solution 1 part in	CONDITION.	RESULT.
1	48	F	5000	Evulsion of nasal polyp, cold snare	Bloodless
2	21	M	5000	Breaking nasal synechiae, blunt separation	Bloodless
3	31	M	5000	Nasal congestion causing constant cough	Relief prompt and lasting
4	21	M	1000	Enchondrosis septum, electro-trephine	Bled freely
5	26	F	10,000	Nasal congestion, spray for patients use	Great relief
6	31	M	10,000	Nasal congestion, spray for patients use	Great relief
7	54	M	10,000	Nasal congestion, spray for patients use	Great relief
8	14	F	1000	Polypoid degeneration and hypertrophied middle turbinate uncapped and snared	Bloodless
9	21	M	1000	Polypoid degeneration and hypertrophied middle turbinate uncapped and snared	Bloodless
10	26	F	1000	Enchondrosis septum, electro-trephine	Complete subsidence of symptoms and eventual recovery
11	32	F	10,000	Acute rhinitis, acute infection of maxillary antra, spray used by patient every two hours	Complete subsidence of symptoms and eventual recovery
12	45	M	10,000	Acute rhinitis; used by patient	Relief
13	28	M	5000	Discomfort and tension after Asch operation	Immediate Relief
14	52	M	5000	Epistaxis (ulcer septum)	Immediate Relief
15	50	F	1000	Removed degenerated middle turbinate	Bloodless
16	28	M	10,000	Subsequent to operation enchondrosis septum	Used at home with comfort
17	7	M	10,000	Acute rhinitis	Relief
18	10	F	10,000	Acute rhinitis	Relief
*19	35	M	Tablet	Enchondrosis septum, trephine	Bloodless
*20	18	F	Tablet	Enchondrosis septum, trephine	Bloodless
21	28	M	10,000	Nasal polypi	Bloodless
22	22	M	10,000	Enchondrosis septum, trephine	Slight bleeding
23	23	M	10,000	Excision middle turbinate, Holmes' scissors	1-5000 Stopped hemorrhage
24	18	M	5000	Enchondrosis septum, trephine	Bloodless
25	22	F	5000	Hemorrhage after packing excision middle turbinate	Slight bleeding checked by 1-5000
26	23	M	10,000	Snaring lower turbinate	Slight bleeding checked by 1-5000
27	30	M	10,000	After operation middle turbinate, spray two days	No bleeding
28	35	F	10,000	Excision middle turbinate	Bloodless
29	19	F	10,000	Cystic degeneration inferior turbinate, snare	Brisk hemorrhage ceased after packing 1-5000
30	18	F	5000	Excision middle turbinate	Bloodless
31	62	F	1000	Angioma septum, cold snare	Bled freely, but checked at once by 1-1000
32	14	F	5000	Exostosis septum removal	Bled freely, but checked at once by 1-1000.
33	21	M	1000	Deviated septum, Asch operation under Cocain	Bloodless
34	25	F	1000	Excision middle turbinate	Nearly bloodless, slight bleeding checked by 1-10000
35	45	M	5000	Enchondrosis septum	Slight

*Note—No. 19 and No. 20 were treated with a solution of the tablet of Adrenalin Tartrate. 1 in 1/2 oz. of water makes a solution of 1-1000.

OBSERVATIONS AND TABULATED REPORT OF THE RESULT OF ONE HUNDRED AND FIFTY OPERATIONS FOR APPENDICITIS.*

BY LEON BRINKMAN, M. D.

of Philadelphia

My object in presenting a paper on a subject which has received such an exhaustive discussion, as has appendicitis, is to present the results ob-

tained in a few anomalous cases and to state the conclusions which the balance have forced upon me. I know of no other class of surgical work which calls for as much acumen to arrive at a differential diagnosis as is required in obscure cases in appendiceal surgery. The initial symptoms in an acute attack of appendicitis, under ordinary circumstances, are so plain, and, in a few instances, so easily recognized, that I can scarcely conceive how the disease is permitted to advance in so many patients to the point where the pus forms, or why their lives should be jeopardized by waiting for something to turn up. The cases upon which my observations are based have not been selected, but have been taken as they come, good and bad, acute and chronic, and will therefore present the average good and bad cases in each variety. The mortality is low, but I do not dare hope ever again to attain such good fortune. The more cases one sees of this dangerous affection, the more difficult they become from an operative point of view, because we meet with more neglected cases and our mortality must therefore of necessity be greater.

The ordinary symptoms of appendicitis I shall dismiss with but mere mention. The acute onset of the disease associated with nausea or vomiting, the colicky pain, the tenderness and rigidity are characteristic of acute inflammatory disease of the appendix. These symptoms may not all be present in the early hours of the attack. The acute onset of any abdominal pain should always make the physician suspicious of appendicitis and under the circumstances invites an examination of the abdomen to ascertain the cause of the pain. If this were done systematically there would not be so many neglected cases of appendicitis. Unfortunately, only too often, a hypodermic injection of morphine is administered which tends to obscure the symptoms. Upon inspection, the abdomen of a patient suffering from an acute attack of appendicitis, will show voluntary restricted movement and that they favor the affected side. Upon palpating the abdomen lightly, a distinct sense of resistance is noticeable, which is lost, however, if the pressure exerted is too great. As the region of the inflamed appendix is approached, the amount of tenderness, pain, and rigidity is found to increase.

The location of the pain, tenderness and rigidity depends upon the site which the appendix occupies. If the appendix is retro-cecal the symptoms will be confined to the right iliac fossa; if the appendix points toward the median line, the maximum focus of the symptoms will be shown there; while, if the appendix points into the pelvis, and the tip alone is involved, the symptoms will be confined almost entirely to the left side of the abdomen. If the body of the organ is included in the inflammatory process there may also be right-sided symptoms. In certain cases of appendicitis the onset of the attack is associated with pain which has been mistaken for kidney colic. This pain should not be mistaken for a renal affection, for it is an inflammatory pain and is not associated with any urinary disturbance.

The symptoms of appendicitis after pus formation are more readily recognized. The symptoms of the onset of the disease are still in evidence, viz., pain, tenderness, and rigidity. The pain in the later stage of the disease is continuous, while the pain

*Read before the Philadelphia County Medical Society, March 13, 1901.

of onset is paroxysmal. The tenderness is more marked after pus is present and becomes aggravated as the collection increases in size and amount. The rigidity gradually increases as the disease advances until the abdominal wall becomes stiff and board-like to the touch. If the appendix is located in the pelvis and a purulent collection is formed, then the left-sided symptoms are more marked and the vesical symptoms are aggravated. When the bladder is full or partially filled, the discomfort is not so distressing, but during micturition and after the bladder has been emptied, the contraction of the bladder makes traction upon the adhesions, thus increasing the pain. The purulent stage of appendicitis is most frequently associated with a mass. The location of the mass is variable and is dependent upon the position of the appendix; it may be found behind the cecum, in front of the bladder, on the left side of the abdomen (iliac fossa), toward the median line behind the mesentery, and even extending down upon the thigh. Although fecal impaction has been considered as one of the causes of the mass in appendiceal disease, I have never found this to be the case.

The temperature or pulse-rate are valueless as indications, in appendicitis, of how far the disease has advanced or what may be the condition within the abdominal cavity. I have seen on more than one occasion a patient with a large purulent collection, whose temperature and pulse-rate were normal; while, in other instances, there was every indication of the presence of pus with high temperature and rapid pulse and yet operation revealed only a moderate invasion, microscopically, involving the mucus and submucus coats of the appendix alone. In one instance I saw a child which had an almost typical typhoid temperature where operation revealed numerous small abscesses in the tip of the appendix.

The diagnosis I have found easy to make with but few exceptions. The cases in which there was any doubt occurred entirely with the female sex and were associated with some disease of the adnexa. In one case there had been a previous history of dysmenorrhea; there was no apparent disease of the tubes or ovaries on vaginal examination; still, a mass was noted in the right broad ligament, which was tender to the touch and imparted to the patient the same sort of pain which was elicited on palpating the abdomen; she had the classic symptoms of the onset of an acute attack of appendicitis. Operation revealed a purulent collection in the pelvis, a perforated appendix which was adherent to the right broad ligament, tube and ovary. There was some question as to the propriety of leaving the tube and ovary on the affected side owing to involvement in the abscess wall and to the fact that they had been included in the inflammatory process. They were not removed and at the present time are in normal condition. The patient at this time is free from her dysmenorrhoea.

In another instance the case was complicated by an extra-uterine fetation on the right Fallopian tube. The patient suspected pregnancy and had been examined by me some weeks previous to the attack of appendicitis, her pelvis was found to be clear. Four weeks later she was suddenly attacked with an acute abdominal pain with all the symptoms of an

acute attack of appendicitis. Owing to the previous question of pregnancy, a vaginal examination was made, when a mass was revealed which I made out to be an extra-uterine pregnancy. Operation revealed an acute appendicitis with the appendix attached to the right broad ligament, and an unruptured extra-uterine pregnancy of the right Fallopian tube. With all the symptoms present, the diagnosis should be easy. The initial symptoms of pain, tenderness and rigidity, with nausea or vomiting make the diagnosis.

A differential diagnosis must be made between appendicitis and intra-abdominal lesions other than appendicitis do we have the precise sequence of symptoms that are almost always present in acute disease of the appendix. The acute intestinal disturbances, such as enteralgia and indigestion, like appendicitis, have an acute onset, but differ from it in that they do not have the localized tenderness and rigidity. The pain in appendicitis is aggravated by pressure, while in enteralgia it is somewhat relieved. In appendicitis the pain does not remain at the point of the abdomen in which it makes its appearance, but becomes localized later at the focal point of the appendiceal inflammation, while in acute indigestion and in enteralgia the pain remains localized about the umbilicus.

The differential diagnosis between typhoid fever and appendicitis should not be a difficult one to make on account of the prodromal symptoms on the one hand and the acute onset on the other. If the patient, the subject of an attack of appendicitis, is seen late after pus has formed, and there is a hectic temperature, then it might present some features in common with typhoid fever. A careful examination of the abdomen, and a review of the history of the onset will clearly demonstrate which affection the patient is afflicted with. In appendicitis there is a history of sudden onset, with pain, tenderness, nausea or vomiting and paroxysmal localized pain; while in typhoid fever the history will show that the patient has suffered from backache, headache, epistaxis, lassitude, and the classical temperature record with diffused abdominal pain.

From acute intestinal obstruction appendicitis can be readily diagnosed from the indifference of onset. The symptoms in acute intestinal obstruction are ushered in with more acuteness, the pain is not paroxysmal as it is in appendicitis, but remittent; the pain is always referred to the neighborhood of the obstruction, and this is most commonly found in the region of sigmoid flexure of the colon, unless it is an obstruction from a band, or diverticulum, when it will be found in the lower part of the abdomen. There is absolute constipation in obstruction while in appendicitis, there may be either diarrhea or constipation. There is usually subnormal temperature in obstruction, while in appendicitis the temperature is practically unchanged. In intestinal obstruction there is discharged from the bowel both blood and mucus. Shock is not associated with appendicitis except when perforation occurs or general peritonitis sets in, while shock is a common symptom of obstruction.

The inflammatory disease which is most difficult at times to differentiate from appendicitis is acute cholecystitis, with or without

gallstones. Both appendicitis and acute cholecystitis are inflammatory diseases, and are both usually confined to the right side of the abdomen; they have symptoms alike, viz., pain, tenderness and rigidity. If the patient is seen early it will be noticed, if suffering from acute inflammatory disease of the gall-bladder, and if free from adhesions, that the distended gall-bladder will move with respiration; again, that the gall-bladder occupies a higher position in the abdomen and that a line drawn from the tip of the ninth rib to the umbilicus and divided at its center will approximately indicate the position of the normal gall-bladder: it is at this point, or thereabouts, that the maximum amount of tenderness and pain will be found if the gall-bladder is involved. In appendicitis the maximum focus of the symptoms will be noted at or about McBurney's point. I had the opportunity of examining a patient, some time since, who had had several attacks of hepatic colic; quite recently he had an acute attack of appendicitis. Examination demonstrated a tender spot over the appendix and another over the gall bladder. Operation revealed an enlarged and cystic appendix; the gall bladder was found considerably distended and contained twenty stones.

The prognosis in appendicitis is good, except as I have before stated, when operation has been delayed. In cases of appendicitis which have been permitted to advance to the suppurating stage, operation is always attended by more uncertainty, not only on account of the condition when seen, but as much in consideration of the remote effect of the disease plus the effects of operation. These may be summed up as the sequelae, viz., liability to acute intestinal obstruction whether due to adhesions: to contraction of the abscess wall and kinking of any loops of bowel included in the abscess wall; or from a parietic state of the bowel from sepsis or from distension: or a deposit of lymph which will interfere with the peristalsis of the bowel.

The cases operated upon for chronic diseases all made a good recovery. Of the acute cases operated upon four died, giving a mortality in all the cases of two and two-third per cent.

The cases that died I will relate in brief:

CASE 1.—E. was aged twenty-four years, he had had five attacks. The diagnosis was made thirty-six hours after the onset. The appendix was gangrenous and greatly distended with pus. This patient did badly from the time of operation until his death. The vomiting persisted and the patient presented all the evidence of peritonitis. The bowels were very hard to move, although the patient passed flatus occasionally. The abdomen was distended. Autopsy revealed an ileus, which had its origin in the small bowel at a point corresponding to a small deposit of lymph which was located in the mesentery. The peritoneal cavity contained clear fluid. At the time of the operation a drop of pus escaped from the appendix as it was removed and dropped on the abdominal wall; this spot subsequently broke down and left a sharply defined ulcer showing the intensely infectious nature of the contents of this appendix.

CASE 2.—R., aged nineteen years, had three attacks of appendicitis. The diagnosis was made forty-eight hours after the onset. The operation took place seventy-two hours after the onset. A large abscess was found extra-peritoneally, a second abscess existed within the peritoneum and was not entirely walled off; the appendix was gangrenous as well as the omentum. The appendix and gangrenous omentum were removed. The wound was packed, no attempt being made to clean the abdomen. The patient died twenty-four hours later from sepsis.

CASE 3.—B. was aged twenty-four years. This was her first attack. The diagnosis was made thirty-eight hours after the onset. The operation occurred twelve hours later. A small abscess was found, the appendix was adherent to the iliac vessels. The appendix was removed. Drainage was employed. Death occurred twelve hours after operation and was due to heart failure induced by suddenly arising from the recumbent position during the absence of the care-taker.

CASE 4.—Miss M., aged twenty-two, had one attack. She was sick one week when the diagnosis was made. She was operated upon on the day the diagnosis was made. The condition of the abdomen found at the operation was as follows: A huge abscess extending from the lower border of the ribs to the iliac crest, and bounded internally by the median line. The appendix was perforated. The appendix was removed and the abscess cavity drained. Ten days later the temperature suddenly shot up and the patient became delirious. The abdomen was reopened and a secondary collection evacuated. The patient died two days later. The autopsy revealed a pyelo-phlebitis with multiple abscesses of the liver.

The treatment of appendicitis has for some time past been considered as properly within the province of the surgeon. If this is so considered, then it must be proper and fit for the surgeon to select such means or measures as will best safeguard the sufferer and restore him to health. It is incredible that, at this time, there should be any discussion as to the advisability of removing a diseased organ; or as to the proper time for its removal. The best of the diseased appendix for numerous reasons: to results are always obtained by the prompt removal prevent pus formation; to avoid avoidable complications; to exclude peritonitis, if not already present; to insure a speedy recovery with the least likelihood of sequelae, which must come in a certain percentage of cases if the disease is permitted to advance until pus has formed or the peritoneal cavity invaded with pus from a ruptured appendix. The treatment of appendicitis should be confined to surgical measures and these varied to meet the individual cases, either acute or chronic. There can be no fixed or fast rules laid down to govern these cases, but certain surgical principles are involved which, if observed, will make our results all that can be desired.

In two of the cases the purulent collection was evacuated and the appendix left undisturbed, as I did not deem it wise to remove the organ at the time of operation on account of the desperate condition of the patient. After the immediate effects of the disease were under control, the appendix was removed, thus completing the otherwise unfinished procedure. I believe it is bad surgery to make this a universal practice, but there are, however, isolated instances where conservatism, if it may be so called, can be properly practiced.

An analysis of the tabulated statistics is of interest. Of these cases 5 had the diagnosis made at once after the onset of the disease; 11 within nine hours; 9 within fifteen hours; 5 within twenty-four hours; 4 in thirty-six hours; 15 in forty-eight hours; 9 in three days; 5 in four days; 1 in six days, and 1 at the expiration of a week. In one case the attack was fulminating.

Operations were performed in the acute cases as follows: 4 within ten hours after onset; 11 after fifteen hours; 11 after twenty-four hours; 4 after thirty-six hours; 5 after forty-eight hours; 13 after three days; 3 after four days; 5 after five days; 1 on

POINTS CONNECTED WITH THE GENERAL ETIOLOGY AND PATHOGENESIS OF DIABETES MELLITUS.**

HENRICH STERN, PH. D., M. D.

of New York.

It may appear a paradox, but it is a fact that, in the United States, at least, the mortality statistics afford us the most reliable method of obtaining certain general etiological data of diabetes.

I have revised and studied the mortality statistics of New York City for a period of 11 years (1889-99 incl.), pertaining to diabetes mellitus,** and in the following are given a few of the data and conclusions derived therefrom:

Sex: Of 1867 deaths from diabetes mellitus, 931, that is, almost 50%, occurred in females. This proportion differs widely from the supposition that the affection is much more fatal in males than in females. Former mortality reports have shown that from two to two and a half times more men succumbed to this malady than women. It is but consequential to assume that the death rate from diabetes mellitus stands in direct proportion to the frequency of the disease itself, and that in New York City about equal numbers of both sexes are afflicted with it.

Infantile Diabetes: Judging by the mortality from diabetes mellitus in childhood, the period when this disease almost always terminates fatally, we may adduce that this malady is a rare affection in infancy and early adolescence. I found 4 cases of death from diabetes mellitus in infants below 1 year of age during the 11 years from 1889-99; at 1 year of age 1 death; at 2 years of age, 2 deaths; at 3 years, 2 deaths; at 4 years, 4 deaths ensued, that is 13 instances in which the disease terminated fatally below the 15th year of life. Between the 5th and 9th year 11 cases of death are on record for the period in question; from the 10th to 14th year of life I came across 17 recorded instances; and from the 15th to the close of the 19th year the mortality from this affection amounted to 38. The total mortality from diabetes in infancy and early adolescence being 79 forms about 4.25% of the total deaths from this disease during this period of 11 years. Of these 79 deaths, 55, which is over 70%, occurred between the ages of 10 and 19. The period of puberty seems to be without influence upon the production of diabetes mellitus or upon its fatal termination.

Sex in Infantile Diabetes.—Of the 13 instances of death which occurred under 5 years of age, 3 took place in females. Among the 66 other instances of deaths from diabetes in early life, 33 ensued in males and 33 in females, exactly 50% in each sex. The external conditions of life in the United States as a general rule are in the mean the same for both sexes to the 20th year; a fact to which the equal

distribution of the disease in both sexes may be well ascribed.

Race.—The death rate from diabetes in the colored race is exceedingly low. This may be due to either the infrequency with which the pathologic condition appears in the Ethiopian race or to its occasional non-recognition when it is present. Of the 15 instances of death from diabetes which ensued among the colored population of New York City, between 1889-'99, 9 occurred in males and 6 in females.

Hebrews, no doubt, are more commonly affected with chronic glycosuria than is the nation among whom they dwell. The death certificates in the United States furnish no direct evidence whether the deceased belongs to the Jewish race or not nor in many instances does the name disclose the racial identity. Those buried in the Jewish cemeteries were classed by me as Jews. A few others of undoubted Jewish origin (personal name, name of parents, place of birth) not interred in specific Jewish burial grounds, were also counted among the Jews. Out of a total of 202 deaths in 1899, 54, that is, about 25%, occurred in Jews; of these 21 were males and 33 females.

Of those born in Ireland, 37 succumbed to diabetes in 1899. Taking the Irish as a race—as I have done with the Jews—adding those who were born outside of Ireland of Irish parentage or who are of Irish descent, we have a total mortality of at least 51—22 males and 29 females. This figure also forms over 25% of the total mortality from diabetes mellitus.

The frequent mortality from diabetes mellitus in the Jews and Irish may be ascribed to manifold causes; mental exertion, the characteristic modes of living, gluttony, alcoholic intoxication, etc., might be considered predisposing factors in the production of the diabetic state but the cardinal predisposing cause in my opinion, is the breeding in and into which, in a very pronounced degree, the Jewish, as well as the Irish race, still adhere.

Frequency of Diabetes Among the Poorer Classes.—Diabetes mellitus is not a special visitation upon the well-to-do as is commonly supposed; but it occurs frequently among the working people between whom gluttony and leisure hours are the exception. Among the 102 males who died from diabetes in 1899, 66 at least were working for a livelihood or were dependent upon others, and lived in tenement houses.

For clinical purposes we may ascribe the various glycosurias to one or more of the following causes:

1. To excessive ingestion of carbohydrates—alimentary glycosuria.
2. To diminution, or functional disturbance, or excessive or abnormal disintegration of the erythrocytes:—glycosurias following the introduction of poisons and toxins, or the perverted function or removal of certain glands and organs—hematogenic glycosuria. (Pancreatic diabetes—Seegen's grave diabetes).
3. To traumatism—neurogenic glycosuria.
4. To interference with the glycogenic function of the liver to the extent that the ingested carbohydrates are not utilized normally—common or hepaticogenic diabetes.

*Diabetes mellitus. The mortality therefrom in the city of New York during the period from 1889 to 1899; from the official records. Comments.—Journal Am. Med. Ass'n., Jan. 28, 1901.; also the mortality from diabetes mellitus in the City of New York (Manhattan and the Bronx), in 1899. Classified according to months, age and sex; also an expose as to nationality, duration of residence in the United States, occupation, direct causes of death and accompanying diseases.—Med. Record, Nov. 17, 1900.

**Read at the meeting of the New York Academy of Medicine, March 19, 1901.

5. To a general protoplasmic deterioration and plasmolysis—diabetic deterioration.

It would be beyond the scope of this paper to dwell at length upon the special and direct underlying factors of every type of glycosuria. Besides, the primary cause of all hyperglycemic conditions—excepting the alimentary form—seems to be one and the same, and the true pathogenesis of one clinical type of glycosuria or diabetes appears, therefore, the true pathogenesis of all the others. Assuming that the primary stimulus of hyperglycaemia acts by the medium of the blood, the clinical subdivision, hematogenic glycosuria or diabetes, although per se not comprising the other before characterized clinical forms, gains at once special importance. In the following I shall consider only the hematogenic form and the most typical of all diabetic conditions—the diabetic deterioration.

HEMATOGENIC GLYCOSURIA AND DIABETES.

Ludwig Bremer's method of diagnosing diabetes from a drop of blood * while in all likelihood will never supplant in general favor the older and more approved tests, for glycosuria or diabetes, has served on the other hand, the admirable purpose of drawing attention to a hitherto unknown factor in hyperglycaemia. The St. Louis physician was the first to observe that erythrocytes of diabetic blood stained with an eosin-methylene-blue solution, did not appear red or brown-red, as would the red corpuscles of normal blood, but that they attain a yellow or yellowish-green coloration. Having found that the specific reaction does not depend on the presence of dextrose, as it does not ensue in artificially saccharated healthy blood on the application of the eosin-methylene blue solution, he concluded that there is a foreign substance in the diabetic erythrocytes which calls forth this unusual phenomenon.

The reducing power of diabetic blood upon a weak solution of methylene blue, first observed by Williamson,* confirms, to a certain degree, Bremer's conclusions. This reaction, due in part to the reducing quality of dextrose, cannot be ascribed to the latter alone, as the amount in which this substance usually occurs in glycosuria does not suffice to bring about the very pronounced methylene blue reduction, and as it will take place even then, when the diabetic had not excreted glucose for some time.

*Centralblatt, f. d. med. Wissenschaften, 1894, No. 49; Med. News, Feb. 9, 1895; "an improved method, etc.," N. Y. Med. Journal, March 7, 1896. "Die Diagnose des Diabetes Mellitus aus dem Verhalten des Blutes gegen Anilinfarben," Centralblatt, f. innere Med., 1897, No. 23. In the last communication the author speaks of the reaction ensuing when stained with Congo red, methylene blue, and Ehrlich-Blandi's fluid. When treated with Congo red and methylene blue diabetic blood does not appear colored as the normal blood; treated with the Ehrlich-Blandi fluid, diabetic blood turns orange, and normal blood assumes a violet coloration.

*Lepine (Genese des differentes formes de diabete sucre. Sem. Med. 1897, p. 259) and Gubler and Assolant (Anomalies pathologiques bei Diabetes mellitus und Glycosurien, Wiener Klin. Wochenschrift, 1897, No. 46), found a similar coloration of the blood of some other pathologic conditions (leucocythaemia, pseudo-leukemia, leucism, etc.). Gubler and Assolant (Nacht. Bull. de Scienze Med. di Bologna, Nov., 1897) did not observe the reaction in the blood of other diseases (he did not examine leukemic blood). I have seen the same reaction in extreme cases of leucemia, and in cases of extreme and persistent states of very low blood alkalinity. The reaction does not seem to be definitely pathognomonic of diabetes or glycosuria, but it is possible that the reactions in the blood of various disorders are called forth by different alterations.

Notwithstanding these facts,* Nardi thinks it highly probable that the reaction with anilin dyes is the result of the presence of free glucose in the blood of the diabetic. Diminished alkalescence of the blood has been thought the cause of the reduction by some authors; the blood alkalinity in diabetes, however, especially in its lighter manifestations, where a rigid meat-fat diet is not observed, is hardly ever decreased.

The reaction of diabetic blood upon certain anilin color stuffs appears to be a purely chemical process. This inter-action may be due to the presence of an abnormal element in, or the absence of a normal substance from the diabetic blood, or to both eventual factors together. Bremer* opines that a foreign body is probably combined with the hemoglobin; I. Loewy** concurs with this view in general, and ascribes the changes in the blood as caused by deviations in the structure of the erythrocytes.

As early as 1896 I approached this subject. At that time I was inclined to Ebstein's theory, which supposed that the general oxidizing qualities of the diabetic organism were more or less impaired, an assumption which, in the light of modern research, appears untenable. (Substances far more difficult of oxidation than the carbohydrates are burned up in the body of the diabetic. Tartaric, citric, malic and other organic acids oxidize, and, like in the healthy state, are excreted as salts of Co^+ with the urine of diabetes. Benzol oxidizes to phenol and hydrocarbons, less oxidable in the human system than amylaceous ingesta are completely oxidized to Co^+ and H^+O and serve as a most valuable fuel for the glycosuric and diabetic organism. Moreover, levulose, invertin, inosit and mannit are also burned up in the body of the diabetic.* It seems that we can only speak of diminished oxidizing qualities in the stages of acetoneemia and acidosis.)

Taking the theory of a primary sub-oxidation for granted, I inferred that there must be a certain connection between Bremer's phenomenon and the oxygen-carrying property of the diabetic red blood corpuscle. Continued examination of the diabetic blood with the inadequate means then at my disposal apparently confirmed my supposition that the oxygen had been partially replaced from its hemoglobin combination, and as carbon monoxid intoxication is nothing else but a deficient oxygenation, I considered carbon monoxide of catabolic origin the replacing factor.

It is true CO hemoglobin could never be identified spectroscopically, and those instances in which I detected CO in hyperglycemia by chemical agents, were, to the greater part, not such of true diabetes;* in the latter affection I thought to have found Co a few times, but only during the very last stage. In "A contribution to the pathogenesis and etiology of diabetes mellitus," which appeared in the *Medical Record* of December 18, 1897, after stat-

ing that the stage of diabetic auto-intoxication is characterized by the presence of dimethyl-ketone in excess of ethyl-diacetic, and of levorotatory oxy-butyric acids, I continued that I thought to have of late succeeded in identifying an abnormal chemical substance in the blood of diabetics who have died in a comatose condition. The foreign element in question detected by the NaOH and Katayuma's tests appeared to be carbon monoxid. Fearing prematurity, I did not then mention the details of my observation.

The non-detection of CO in the blood of my diabetic cases prior to the establishment of far advanced toxemia, furnishes by no means conclusive evidence of its absence, for in many instances of chronic CO poisoning we have to deal with, but infinitesimal amounts of this substance.

The negation of a primary and general disturbance of the oxidizing qualities of the diabetic, however, precludes carbon-oxydemia as a causative factor of true diabetes and relegates it, together with the other known toxic principles, to the rank of an anomalous metabolic condition. Furthermore, I have since convinced myself sufficiently that the changes in the cellular substance of the diabetic red blood corpuscle, evidenced by the anilin dye reaction, are neither the direct or indirect result of CO intervention.

The almost characteristic behavior of the diabetic erythrocyte must be due to another factor which might be either the result or cause of the diabetic condition. This abnormal element in the cellular substance of the erythrocyte is presumably of autochthonous formation, perhaps, though it takes its origin from exogenetic influences. If the foreign substance has arisen from within the organism, it is either enterogenous or histogenous. It does not seem to be due to a retention anomaly as carbonaemia and carbonoxydemia per se fail to reduce the anilin dye stains.

If the substance in question were derived by resorption from the gastro-intestinal canal, it could not become an almost permanent factor in the blood, as this would pre-suppose a long-continued, uninterrupted absorption of the products of intestinal hyperfermentation and putrefaction, a condition hardly ever prevailing, and in my experience not frequent in diabetes. On account of this and some other less important reasons we have to regard the erythrocytic foreign element—not considering at this moment its possible ectogenesis—as a product of abnormal cell and organ activity or disintegration. Thus the foreign substance, whether it originated by perverted plasmolytic or nucleolytic processes, or by anomalies of internal secretions, may safely be classified among the toxic principles.

The possibility of an ectosystemic origin of the substance in question deserves some attention.

A considerable number of authors have observed the appearance of diabetes in formerly healthy persons after they had come into more or less intimate contact with diabetic individuals. The transmissibility, therefore, of the affection seems feasible, although no convincing proof has been given for it. One could surmise that the abnormal blood constituent represented the metabolic products of a specific bacterium, and that the potency of this

toxin gave rise to the glycosuric phenomenon. Some observers investigated the subject of diabetic infectivity more closely, but I cannot accept their meagre and contradictory results as conclusive evidence for the same.

I have dwelt at some length on the foreign substance in the diabetic erythrocyte, as notwithstanding the hyperglycaemia, it appears to be the only tangible and ever-occurring foreign element in the blood of diabetics. Whether it forms the etilogic substratum, or if it is but another of the metabolic products of the diabetic condition, is a question which the future has to answer.

The Diabetic Deterioration.

While Traube,* Ebstein,** Cantani*** and other observers distinguish between a mild and grave form of diabetes, they contended that both are manifestations—differing in degree only—of the same directly underlying pathologic condition, and assumed that the severe form was but an advanced stadium of the lighter type.

I. Seegen**** whose fundamental investigations on the production of sugar in the animal organism have as yet met with little appreciation, was the first to recognize two distinct, and, of each other, entirely independent clinical types of the diabetic affection. He demonstrated that the one form—the excretion of sugar resulting from the failure of the liver cells to normally convert the ingested carbohydrates—bears no relation to the other type which owes its origin to the inability of the entire or almost the entire organism, to utilize the sugar conveyed to its structure by the blood.

The present writer has described a third clinical form of diabetes, the diabetic deterioration.*

These three clinical varieties of diabetes emanating respectively from three distinct *direct* causes, seem, however, to be but the consequence of one and the same *fundamental* disturbance.

They may be thus differentiated:

1st form.—The glycosuria disappears after complete or partial exclusion of carbohydrates. The excreted dextrose is due to deficient glycolysis.

2nd form.—The glycosuria persists after the complete exclusion of carbohydrates. The excreted glucose is due to proteolysis.

3rd form.—The continued excretion of dextrose concurs with larger amounts of nitrogen egested than were introduced with the nutriment. The excreted dextrose is due to plasmolysis.

Close observations of a certain type of diabetics, conducted by me,* have demonstrated that diabetic azoturia is not always the result of hyperingestion of albumins, and that in this instance the amount of nitrogen excreted most always exceeds that of the nitrogen introduced with the nutriment. The last fact, not recognized by anyone before me, points to a third form of diabetes, which directly has little or nothing in common with the so-called pancreatic type of the affection.* In experimental pancreatic diabetes in animals fasting or under an exclusive

meat diet, Minkowski** observed a permanent ratio between urinary dextrose and nitrogen. The proportion of dextrose to nitrogen varied in these instances between 2.62:1 and 3.05:1; the mean figure given by Minkowski being 2.8 D. to 1 N.

In my cases, which a priori are at variance with artificial diabetes, the proportion of D:N, under similar conditions, was most always a different one. For instance, in case I, of my observations, which I select at random, the following data were obtained:

Patient under an exclusive albuminous diet for 13 days; average daily amount of albumin ingested, 185 grams., containing 28.86 gms. N.; average daily amount of urine, 3002 c. c.; average daily amount of dextrose in same,*** 5.5%, that is, 165.1 gms.; average daily amount of carbamid in same, 3.2%, that is, 96.1 gms., containing 44.9 gms. nitrogen;**** average amount of nitrogen plus in urin, 16.04 gms.

Proportion of dextrose to nitrogen, 3.67:1. Patient fasting for 17 hours (water in moderate quantity). Amount of urine for 24 hours (including 7 hours after fast), 1850 c. c. Amount of dextrose in the same, 3%, that is, 55.5 grams. Amount of carbamid in the same, 3.8%, that is, 70.3 grams, containing 32.85 grams nitrogen. Proportion of dextrose to nitrogen, 1.69:1.

The non-existence of a constant dextrose-nitrogen ratio tends to prove the discrepancy between the third form of the diabetic affection and experimental pancreatic diabetes.

Minkowski is of the opinion that his figures express quantitatively the production of sugar from albuminous substances in the organism, and that after the removal of the pancreas the total quantity of the sugar thus produced is excreted by the urine.

Admitting that Minkowski's figures are expressive of the sugar production from albumin in the organism, then the relation of D:N in the urine of some of my cases must be exceedingly atypical, and this the more so, as the amount of nitrogen ingested was mostly less than that eliminated by the kidneys and faeces.

During the 13 days of albuminous diet the average daily nitrogen plus in the urine amounted to 16.04 grams.

Utilizing Minkowski's figures and calculating from the N ingested, the amount of urinary glucose should be 80.8 grams. The total daily average quantity of urinary glucose amounted, however, to 165.1 grams. Therefore, 84.3 grams of glucose more were contained in the urine than presumably have been derived from the nutriment.*

*As stated before, the same primary cause seems to stand at the foundation of every diabetic affection. The pathological type clinically is to be counted at once among the haematogenic forms.

**Arch. f. Experiment. Pathol. u. Pharmacol. Bd. XXXI.—Ueber die Nahrung und die Ausscheidung bei Diabetes.

***Through a typographical error, the percentage of glucose was given as 8.4; 8.1; 8, and 6.5, whereas it should read 5.4; 5.1; 5, and 6.

****Crea does not present the total nitrogenous excretion: about 7.5 per cent of N is contained in other urinary constituents. In my later investigations I have determined the total N output.

*I have no reason to doubt that the patient adhered conscientiously to the prescribed and minutely specified albuminous regime. He certainly did not partake of larger quantities of nitrogenous material, as he had developed an aversion to it. In case he should really have transgressed and partaken of carbohydrates, this would have only augmented the intensity of the dextrose output, which per se, is of little moment in our considerations.

We have, consequently, an unaccounted for plus of D. 84.3 to an unaccounted for plus of N, 16.04. That is, a proportion of 5.25:1.

It would lead me far beyond the limits of the allotted time were I to dwell upon the points involved in a more exhaustive manner. For the present purpose it suffices to know, that the irregular and inconstant D:N ratio precludes pancreatic diabetes, and that the N output surpassed during a certain period in almost every instance the N introduction.

This third form of diabetes seems to be the manifestation of a specific plasmolytic process.

In the healthy organism a dextrose resembling substance may be normally yielded by plasmolysis, which, after it has undergone succeeding changes, is ultimately disposed of as carbon-dioxide. However, the production by plasmolysis of dextrose or of its precursor, appears to be an abnormal catabolic process, which causes permanent disintegration of the tissue-protoplasm. This specific dissimulation of the living protoplasm, induced, perhaps, by the erythrocytic foreign element, is a limited hemi-metabolic metamorphosis, so to speak, and bears the character of a deterioration; that is, the protoplasm may retain its appearance and may continue to exist, although it has permanently lost its molecular integrity.

This plasmolytic dextrose-carbamid-yielding process I have designated as diabetic deterioration.

In other words, diabetic deterioration is a more or less limited molecular disintegration of plasmotic tissue substance into a carbohydrate body and a non-colloid nitrogenous compound.

A logical and concomitant phenomenon of the hyperexcretion of nitrogen is the progressive inanition of the patient affected with the disease. The glycosuria is persistent, but its intensity does not seem to reflect the progress or the exact stadium of the affection.

CENTRALBLATT FUER CHIRURGIE.

1. Medullary Narcosis. KARL SCHWARZ.
2. Pseudarthrosis of the Terminal Phalanx of the Finger. W. MUELLER.

1.—Schwarz, before using the Bier method of medullary narcosis, now gives his patients gradually increasing injections of tropacocain. In 10 cases the tropacocain was given in doses up to 5 cg. to insure total anesthesia. There were none of the unpleasant symptoms which accompanied the cocain injections, no pallor, sweating, nausea, vomiting, headache, vertigo, or rise of temperature. The analgesia was perfect 10 minutes after the injection. [M. O.]

2.—Mueller reports three cases of complicated fracture of the terminal phalanx of a finger. The first patient had broken the end phalanx of his right index finger, and three months later he found that his finger easily tired when writing. The tip of the finger could be hyperextended, and a Roentgen photograph showed a groove beneath the root of the nail. Operation showed marked pseudarthrosis, which was easily cured by freshening up the edges and then immobilizing the finger. The second case was much like the first, in an older man. Hyperextension was also possible. He would not permit operation. The last case was in a boy of 16, in whom operation affected a speedy cure. His report is well illustrated with Roentgen photographs. The Pathology and Bacteriology of Diphtheria.

—The monograph by Councilman, Mallory and Pearce ("Diphtheria," Boston, 1901,) is a detailed study of the bacteriology and the pathology of two hundred and twenty fatal cases, which in itself is a claim to distinction. The authors confirm the observation, already made, that tuberculosis and diphtheria are often associated; sixteen percent of their cases presented a combination of the two diseases. They do not consider that there is any relation between the two diseases, this percentage representing merely the frequency of tuberculosis at an early age. The mesenteric lymph-nodes, in the cases observed in this series, were more frequently involved in the tuberculous process than either the lungs or the bronchial lymph-nodes. Much attention has been paid to the bacteriological condition of the accessory air cells, and information has been gained that throws much valuable light on the reason for the persistence of the diphtheria bacilli in the nose for such prolonged periods in some cases. The maxillary sinuses were examined in fifty-two cases; of these, both sinuses were the seat of inflammatory processes in twenty-one and one sinus only, in nine. All but three of the double antral cases presented the diphtheria bacillus; but of the single case only three contained that organism. The pneumococci and the pus cocci were often associated with the bacillus of diphtheria in the pathological exudates, which may be mucoid, serous, seropurulent or purulent, and, in some cases, may consist of a fibrinous membrane. It is an important point for practical purposes to determine whether this infection of the accessory air cells occurs as frequently in the cases that recover as in those that are fatal. In eighty-six cases out of one hundred and forty-four, autopsy showed middle ear disease. The diphtheria bacillus was found in enough cases to show that it is capable of setting up a suppurative condition and thus allies itself with the pus-producing organisms. From a study of the membrane the authors are able to say that they have never found the diphtheria bacillus growing in the living tissues nor in connection with those degenerative changes in the epithelium that may be regarded as the primary lesions of the disease.

This observation confirms, if confirmation is needed, the toxemic character of the disease. It seems, from this study, that the beginning of the lesion is due to the toxic action of bacilli, probably growing in the fluids of the mouth or throat. When necrosis is once produced the necrotic tissue forms a suitable culture medium. The membrane formation is due to a combination of degeneration and necrosis of the epithelium and an inflammatory exudation, rich in fibrin factors, from the underlying tissue. The cells may break up into detritus or they may form hyaline masses, and the factors are converted into fibrin when the exudate comes in contact with the necrotic epithelium. The authors believe that there is nothing to be gained by making an anatomical distinction between a croupous and a diphtheritic membrane; there is nothing specific in the membrane formation in diphtheria. This opinion is in line with the evidence of bacteriological examination, that the clinical distinction between diphtheria and benign sore throat is not to be depended upon. We are cordially in agreement with this opinion and would even go farther and say that all cases of sore throat should be subjected to bacteriological examination and that the proper classification of cases of diphtheria is into the bacteriological and the clinical. Degeneration of the myocardium is one of the most common conditions found in diphtheria. The simplest form is fatty degeneration, which may become very extensive. Acute interstitial lesions of two kinds have been demonstrated; in one there is a collection of plasma and lymphoid cells and in the other there is a proliferation of the cells of the tissue. The first variety of interstitial lesion is not dependent on the degeneration of the muscle, while the second is due to that degeneration. The lesions in the lungs are serious and frequent. Broncho-pneumonia is the most common lesion; although atelectasis and inflammatory edema are also common. True acute lobar pneumonia was never found. The scope of the monograph includes a study of the lesions of the spleen, the alimentary canal, the liver, the kidneys, the lymph-nodes, the thymus, the nervous system, the skeletal muscle, the bone-marrow, the pancreas, the adrenals, the thyroid gland

the salivary glands, the testicles, and the pituitary body. Space does not allow of more detailed notice of these sections of the work. The fact that no lesions were found in the adrenals is somewhat surprising, because congestion, hemorrhage and foci of necrosis in these glands are the most common lesions in the experimental disease, whether produced by inoculation with bacilli or by injection of toxins. On the whole, the work is an excellent addition to the literature of diphtheria, both on account of the original investigations described and because of the thorough review of former writings on the subject.

The American Military Hospital in Peking.—It is a source of satisfaction, after reading in some of our home journals the carping criticisms directed against the United States Government and its policy in foreign affairs, to read the highly eulogistic account, given by the correspondent of the *British Medical Journal*, of our military hospitals in Peking. This writer looked upon the occasion of his visit to the United States military hospitals as one of the pleasantest afternoons he spent in the Chinese capital. He learned that the medical arrangements in the American army possess a far higher degree of importance than in the English service. The hospitals are given the best sites, and the amount of skilled labor assigned to the chief medical officer is as unstinted as the funds placed at his disposal. Combatant officers good-naturedly complained that "it's no use trying to get a nail knocked in anywhere else until the hospital is finished." The correspondent was surprised at the number of comforts allowed the American soldier. His diet on active service contains luxuries unknown in the British commissariat. But it is not until the American soldier goes to the hospital that he is really in a position to know how much his Government loves him. The correspondent did not think it an exaggeration to say that the American Military Hospital in Peking could hold its own with most London hospitals. It is certainly extraordinarily high praise to compare favorably an improvised military infirmary with great metropolitan hospitals. But the correspondent makes good and plain his position by entering into details about the equipment and service in these field hospitals. The diet kitchens, the skilled cooks, the trained attendants, the thorough-going antisepsis, the lavish supply of personal comforts, and, above all, the good results obtained in both surgical and medical practice, are some of the features described by his facile pen.

We have thought it worth while to comment on this generous praise from a foreign eye-witness, not because we believe it will surprise the majority of home readers, but rather because it will

be a partial corrective to the detractions of the little clique of domestic critics who never find anything praise-worthy in the American Army on duty in foreign lands, or in the Government behind it.

The Way They Manage Smallpox in Utah.—A correspondent in Utah sends us some information about the smallpox in that State. There is apparently a great deal of it. In March there were 112 new cases in Salt Lake City alone, and quite a good many new ones in April, although the disease is slowly decreasing. The authorities tried very hard to pass a Compulsory Vaccination law, but it was defeated; and it is interesting to note that the legislator, if he deserves such a title, who introduced the Anti-Vaccination bill, subsequently had smallpox in his own family. We should like to believe that this was a special visitation of Providence. It is astonishing how little attention is paid to the disease. One may see the smallpox flag on many houses, and note that the windows and doors are open and that people pass and repass with seemingly no fear of it. One house just by a church had the flag out, and the inmates of the house sat by an open window watching the church-goers. Our correspondent was coming down in the elevator in one of the big business buildings. A young man entered who exclaimed, "Well, I've got it!" It seems that the doctor from whose office he had just come, had told him to go home and nurse himself. His face was full of pustules, but regardless of this fact, the young man walked to the corner and took a street-car. It seems that the Mormons have been "counselled" against vaccination; hence this condition of affairs.

We think this indifference is probably to be explained in part by the mild type of smallpox which is now prevailing almost everywhere in the United States. We called attention in these columns recently to the mildness of this epidemic. The fact is, people have lost their dread of the disease because the disease itself seems to have lost much of its malignancy. How much of this is due to smallpox having become weakened or modified by the process of vaccination, it is of course difficult to say. On the other hand, all epidemics, it must be recalled, move in cycles, and it may be that smallpox in the United States at present is simply presenting its mild phase. In other words, we cannot assure ourselves that the disease may not at any time assume a much more malignant type. In the meantime the inhabitants of Utah seem to be making the most of their opportunities for getting a mild inoculation of the disease without money and with small risk.

The Constitutionality of the Compulsory Vaccination Act Upheld in Pennsylvania. It will generally be found that the misdirected efforts of certain well-meaning persons in opposition to many progressive movements are based principally upon prejudice, misconception, misinformation and want of information. This is peculiarly true with regard to such matters as vaccination, animal experimentation, disease-notification and the like. In the long run a correct decision will be rendered by the sound common sense of those who are not blinded by emotion, but are open to conviction by facts. A rational intelligence must ever prevail over misguided fanaticism, however well intended. It is therefore particularly gratifying to learn that the Supreme Court of Pennsylvania has just decided in an opinion sustaining the decision of the lower court that the Act of Assembly requiring the vaccination of all children desiring to attend the public schools is constitutional. The case in point is one in which an anti-vaccinationist had applied to the courts for a mandamus compelling the principal of a public school to receive as a pupil a child that had not been vaccinated, refusal being based upon a rule of the Board of Education and an Act of Assembly. The demurrer of the plaintiff was overruled by the Court of Common Pleas, and it is the decision of the latter that has just been sustained. The Supreme Court of Pennsylvania coincides with the view that "school directors, in the exercise of a sound discretion, may exclude from the public schools pupils who have not been vaccinated." It goes on to say further: "Whether a resolution excluding from the public schools pupils who have not been vaccinated is a reasonable one is to be judged of in the first instance by school directors. In the present state of medical knowledge, and of convincing opinion of those having in charge the public health, the courts will not say that such a resolution is an abuse of official discretion." This is both sound law and common sense. The utility of vaccination has been established beyond all peradventure and the prejudices of the few must be subordinated to the welfare of the many.

The Rudolph Virchow Stiftung.—The Germans are practical. In nothing is this more evident than in their expression of gratitude. It takes a form that gratifies the object, and at the same time is of direct benefit to a larger or smaller portion of humanity, or an aid to scientific advancement. Think for a moment of the great number of *Festschriften* that have been published in Germany, and published, as a rule, not as is done in America, in a special volume with a limited circulation, but in one of the regular massive German Archives; a special honorary number occupying an entire vol-

ume. For example, we refer to the most recent, the volume of *Deutsche Zeitschrift fuer Nervenheilkunde*, dedicated to Erb. But even this does not seem practical enough for our very practical German friends. Virchow, full of honors, is about completing the eightieth year of his age. He was born on the 13th of October, 1821, and for more than a half century has actively borne his part in the scientific advancement of the world. Now his friends and admirers, not a few, have organized a committee upon whose roll appear the names of practically all the distinguished medical men of Germany, and with these have been associated a committee of foreigners, among whom are the most distinguished names of the world. And the object is not the erection of a monument, or even the endowment of a professorship, but the increase in the endowment of the *Rudolph Virchow Stiftung* in Berlin, by which the committee hope to prepare for the master "the greatest pleasure and satisfaction upon the occasion of his eightieth birthday;" because "the man who directs it, and whose name it bears, has made of it a so distinguished use, for the purpose of the advancement of science."

An Odd Coincidence.—In the chapter of coincidences, the case of Giacomini and his brain should take prominent place. It does not often fall to the lot of a man to describe for the first time some very striking anomaly of the brain; still more rarely does it fall to his lot to die and have some one else discover that he had the very anomaly which he had himself described. Yet this seems to have been the happy fate of Giacomini—an illustration, perhaps, of the truth of the old Greek aphorism that you cannot judge of a man's happiness until after he is dead. Giacomini, an Italian scientist, was the first to describe a second central fissure, just behind the fissure of Rolando. Afterwards Calori described a second case. Since then the cerebral morphologists have been looking eagerly for a third. Dr. Burt Wilder thought he had found it in an educated suicide's brain, but he felt obliged later to say that he was mistaken. Now, by strange chance, Giacomini dies, and his anatomist comes forth and says that in Giacomini's brain is also a second central fissure! We are indebted to Mr. E. A. Spitzka, of New York, for a drawing of this brain, and hope to present it in the near future. In the meantime we should like to have a psychological explanation of this strange happening.

Bogus American Dental Diplomas in Germany.—We have received a communication from one of the American consuls in Southern Germany to the effect that his Consulate has been entrusted by Ambassador White with the investigation of the

matter of the sale of illegitimate dental diplomas in that part of Germany by certain American institutions, especially in Chicago. The abuse has occupied much time for more than a year, and of late has been especially engrossing. The Consulate has been collecting evidence against the scoundrels at home, and working with the Ministry of Justice, the Attorney General's office and the Police Department in Germany to punish the holders of such diplomas. The parties in America have been bold and reckless because their market has been principally abroad, and they seem never to have dreamed that their work could be brought home to them, but the Consulate has succeeded in a number of cases in securing possession of the diplomas, licenses, certificates, etc., and has had them photographed, thoroughly identified under oath, and certified. Copies have been sent to the Governor of Illinois, the National Association of Dental Faculties, the United States Commissioner of Education, and, of course, to the Department of State. Eight prosecutions have been commenced in Germany against holders of such "rags," in one of which conviction was secured on a defective indictment, which was set aside on an appeal on technical grounds, but the case will be retried on a new indictment which had just been found. In another case a conviction is to be expected. The Consulate has just sent to the American State Department a report covering 174 printed pages, giving a full history of the matter, and the Consul has completed a very full brief of the law and facts in a case against one of the chief offenders, at the request of the Minister of Justice in Bavaria. So reckless have the Chicago people been that there is good reason to assume that in 1900 about nineteen hundred illegitimate licenses have been issued in Illinois. The Consul has also excellent ground for assuming that the Imperial German Consulate at Chicago has not been sufficiently careful in the matter, and diplomatic representations will probably be made, and an explanation asked. Whatever may be the ultimate result, the American Consul is making it so very hot for the holders of such diplomas that he has practically closed the market in Southern Germany, and it is believed that the evidence furnished to the American authorities and the press will make dealers at home more circumspect in their transactions. We print the statement of the Consul largely in his own words. This disgraceful business must be stopped, and it rests largely, we judge, with the Illinois State Board of Dental Examiners to explain and to stop it.

The New Living "Siamese" Twins.—Dr. Chapot-Prevost, who successfully operated upon the only other living xiphopagus, has just published a report

of his examination of the new living Chinese twins, Liou-Tang-Sen and Liou-Seng-Sen. In a communication read before the Paris Academy of Medicine (*Gazette Medicale de Paris*, 1901, Nos. 12 and 13), he says that this xiphopagus is on exhibition in Vienna at the Barnum-Bailey circus. After much persuasion he was permitted to make a thorough examination of the twins, who were born in 1887, in Nankong, in a level country, and were their mother's first children. Delivery was uneventful, the father alone officiating. Seng came into the world head first, Tang feet first after his brother. At birth each child was a little under normal in size. There was one umbilical cord with only one placenta. The mother was 20 years old, the father, 18; and there had been no history of twins on either side. Their mother had no children afterward. The twins were breast-fed until they reached the age of two years and a half. The boys began to talk at 18 months, plainly only at three years. Both are intelligent, Tang rather more than Seng. They can sleep on either side. Four years ago they had chicken-pox. Tang taking it one day after his brother. Seng shows the scars yet. They are always happy and hardly ever disagree. They walk and run together, easily, in one direction, but when they attempt to go the other way, with their other sides approximated, there is great difficulty, one going from left to right, the other from right to left. They were 11 years old when they left China, before which time a Scotch physician in Shanghai had examined them. Tang is 1.352m. high, while Seng measures only 1.343m. A year ago each weighed 60 pounds. One can urinate at a time; one will be awake while the other sleeps; and only one may be hungry. From the various measurements, radiographs, and photographs taken, but slight difference has been found between them. The bridge which unites them is 4 cm. long above, 9 cm. below. There is one umbilicus in the center of the bridge, above. As they have grown, this bridge uniting them has also grown, and they now stand further from one another than formerly. The two xiphoid cartilages join inside this uniting bridge, and below them it is probable that the liver and peritoneal cavity of each joins the other. Seng has a double inguinal hernia, Tang right inguinal hernia. Dr. Chapot-Prevost calls them the eleventh reported living case of true xiphopagus, and believes that surgical interference would undoubtedly be successful.

A Plea for the Aspirator.—No error is more common, especially in hospital practice, than mistaking a pleural effusion for a pneumonic consolidation, and *vice versa*. This is due largely to the fact that it is often practically impossible to obtain an ade-

quate history, and that the physical signs are so indefinite that a final diagnosis cannot be made immediately. The differential diagnosis is concerned only with pneumonias of the bases and pleurisy with effusion either of a serous or purulent nature. At the onset of the affection difficulties may arise, especially if a chill be absent and only "stitches in the side" occur. Frequently, in such cases, neither crepitant rales nor friction sounds are present. Only high fever and a typical pneumonic sputum are symptoms which in such a case would give a clue to the correct diagnosis. A careful investigation of the methods of physical diagnosis will, however, sooner or later, even in the most obscure case, show the true nature of the malady. It is true that occasionally pleurisy with effusion, complicates croupous pneumonia, but a change in the symptoms and physical signs will readily denote this. We desire especially to call attention to a condition which sometimes arises, and is, we fear, very frequently neglected, namely, the fact that a pleurisy with effusion (and often an empyema, especially in children and adolescents), is a sequel of croupous pneumonia. If, after the ninth or eleventh day a crisis has occurred, or the acute affection has terminated by lysis, and the fever continues, giving a subfebrile range, and dyspnea and some cyanosis be present, a pleural effusion upon the affected side should be thought of. The temperature may even be markedly remittant and of a septic type, sweating and chills occurring, and acute phthisis of the pneumonic type be thought of, especially if the patient is losing weight rapidly. An exploratory puncture carefully conducted, in accordance with the established laws, will frequently disclose the true nature of the disease. A mistake is frequently made in using a hypodermic needle or a Pravaz syringe for the purpose of puncturing. It must be remembered that a thick serous fluid, and especially pus, will not flow through a narrow needle, and even if its presence be demonstrated by these means, an aspirator will subsequently have to be used, thus inflicting two punctures upon the suffering patient. Harm is never done in aspiration, if only the ordinary care, which should govern us in all operative procedures, is used. Knowledge of the position of the diaphragm, and the intrathoracic organs, will prevent any injury to these. Another feature in the differential diagnosis, often we fear neglected, is the displacement of viscera which is sure to occur in even medium sized effusions. The recognition of the position of the apex beat of the heart, the position of the liver, and the obliteration of Traube's semilunar space, are all points of the greatest importance in the differentiation of consolidation of the lung and fluid in the pleura.

The Trouble in the New York Pathological Institute.—We regret to learn from the *Medical Record* that the State Lunacy Commission of New York, has notified Dr. Ira VanGieson that his services will not be needed after May 1st. We have referred on several occasions in these columns to the trouble which has existed between the State Lunacy Commission and the working staff of this institute. We have always attempted to be judicial in our expression of opinion, but we have feared that the difference was a fundamental one and that it might yet lead to serious impairment of the usefulness of this institution. Dr. VanGieson and his associates represent that we may call the ultra-scientific party. They are actuated by the highest motives and the most laudable zeal to advance the cause of scientific psychiatry. Some of their critics believe that they have taken a too exclusively laboratory view of this science, and that their work has not been sufficiently practical. It is doubtless true that they have extended their field of work beyond the limits that are usually considered essential in psychiatric research. But the zeal and the cultivated intelligence which have led them to do this, are of the kind that have often been the forerunners of important discoveries in science. They can scarcely be blamed because they have sought to throw light from all quarters upon one of the most involved and far-reaching of the medical sciences. If in doing this they have somewhat ignored the immediate practical needs of the hospitals, the fact is not altogether to be wondered at. This is the indictment which has been brought against them, as we understand it, by the Lunacy Commission. They themselves, on the other hand, claim that the ideas of the Lunacy Commission, and even of some of their colleagues in the hospitals for the insane, are crude and not up to date, and that their opponents, indeed, in their zeal for practical administration have shown a failure to appreciate the needs of scientific psychiatry.

We cannot help but believe that where such fundamental differences of opinion exist on such an important topic there must be some mutual fundamental defects. We fear there has been on both sides a lack of adjustability, or of that wise spirit of compromise which is so often essential in the practical affairs of life. At this distance we cannot help but feel that there should have been sufficient sagacity and forbearance on each side, as well as zeal for the common cause, to have brought harmony out of even such discordant elements. The scientific world, and especially the world of psychiatry, may well deplore the results of this unequal contest. It may also well deplore the fact that this contest has involved an acute display of personal feeling which even extends beyond the limits of the

State of New York. This issue has been made to appear to be only another phase of the so-called antagonism of the administrative men to scientific workers. We are not willing to believe that there is as much of this antagonism abroad in the world as is made to appear, but we would rather think that these unfortunate misunderstandings are often due as much to lack of tact as to any inherent or inevitable want of agreement.

For Dr. VanGieson personally, we have much sympathy, and we trust that he will yet find a congenial field in which to work out his plans and theories. The members of the Lunacy Commission will now have an opportunity to show the world by the kind of appointment they make what their real ideas are about the nature of scientific work in mental science. Their opportunity is great; their responsibility is still greater.

The Influence of Intercurrent Disease on the Course of Epilepsy.—The influence of intercurrent disease in a patient already suffering from a well-defined malady has long been recognized, but is, as yet, not understood. In general, it may be said that certain diseases act favorably on the primary condition; as, for example, erysipelas in certain forms of sarcoma; while others exert a markedly unfavorable influence and aggravate the primary condition. Such, for instance, is the effect of a broncho-pneumonia in whooping cough, or measles. Dr. M. J. Voisin has recently published a report of one of his clinics (*La Semaine Medicale*, March 20th, 1901), in which one phase of this problem, the effect of intercurrent disease on epilepsy, is ably discussed. He calls attention to the fact that many diseases of febrile form exert a restraining influence upon the epileptic attacks, while others show a decidedly provocative influence. He has observed four cases of erysipelas in epileptics who averaged two or three attacks a month, with decided symptoms of vertigo. The manifestations entirely disappeared during the acute attack of erysipelas, but with the establishment of convalescence the vertigo reappeared, soon to be followed by the convulsive seizures. The influence of anthrax was not less evident than in the cases which have been described by M. Queriand. In Voisin's patient, the epileptic attacks entirely disappeared with the suppurative symptoms which terminated in the patient's death. The effect of lobar pneumonia and measles is similar and more variable. The attacks usually disappear during the acme of the disease, and then may be increased, or diminished in severity, after convalescence. The association of epilepsy with so prevalent a disease as tuberculosis presents a variety of results. It has been found, however, that the epileptic attacks are less frequent, or disappear entirely,

when the tuberculous process is most acute; and that they reappear when the pulmonary symptoms are ameliorated. Voisin states that variola, acute articular rheumatism, and intermittent fever act very similarly, but points out the interesting fact observed by M. Fere, that when epileptics are vaccinated, there is a decided lessening of the attacks in those patients in whom the virus has taken. An epidemic of diphtheria, occurring in Voisin's service, afforded him the opportunity of observing the effects of the disease itself, as well as the results of antitoxin treatment. Of nineteen patients attacked with diphtheria, four were epileptics. In these it was observed that the attacks disappeared entirely during the course of the diphtheria, and returned in their usual number after the disease had run its course. Of a series of 144 children who received a protective dose of antitoxin, 63 were epileptics. Of these 63, 57 developed an intense erythematous eruption which appeared tardily. It was observed that the eruption was most severe in the worst cases of epilepsy, and in those children who were idiots. Voisin remarks that it is not possible to consider this as an example of auto-intoxication, but believes, rather, that it is dependent upon vaso-motor disturbance in the defective central nervous systems of these cases. The foregoing are the diseases which act more or less favorably upon the course of epilepsy.

Scarlatina is a most serious disease when it attacks epileptics, and the prognosis must be most guarded. In 19 cases of scarlatina which occurred epidemically in Voisin's service, 4 were in epileptics, and these all died within four or five days, while the 15 others recovered uneventfully. Influenza greatly increases the number of epileptic attacks, and its pulmonary complications exert a very deleterious influence on such patients. Voisin mentions the remarkable increase in the number of attacks in certain of his cases. One patient had 174 attacks in five days; and another suffered from the astounding number of 214 in a single day. Typhoid fever also increases the number of seizures. This has been made the subject of a thesis by Dr. Lannois, of Lyons. Three theories have been adduced to explain the effects we have studied. They are, that it is due to the action of the high temperature itself; that it is the result of a toxemia exerting its influence on the nervous centers; and third, that the diminution or the increase in the number of attacks is due to the fact that certain toxins exert an inhibitory action upon the motor tract, while others increase the motor excitability. The last hypothesis is the one which Voisin adopts tentatively. In conclusion, he points out that there is a post-paroxysmal rise of temperature in epilepsy,

usually amounting to five or six-tenths of a degree Centigrade. When the post-paroxysmal rise amounts to one or two degrees Centigrade, or more, the existence of an intercurrent disease should be suspected. This does not apply to the *status epilepticus*, in which a greater rise is common. These observations are of wide general interest, and give rise to many problems, with the solution of which we may reach a more comprehensive knowledge of the pathology of epilepsy, as well as the action of toxins upon the nervous system.

Uretero-Intestinal Anastomosis.—Those who have read the interesting "Historical and Experimental Research" of Dr. Reuben Peterson on anastomosis of the ureters with the intestine, which was begun in the *Journal of the American Medical Association*, February 16th, and continued through six issues of that journal, must have been impressed with the author's painstaking efforts to deal fairly with the subject from every point of view, and his very valuable conclusions regarding the advisability of the operation and the best method of performing it must appeal to every surgeon. The best method of dealing with the ureter injured during the course of an operation, in cases of advanced disease of the bladder, and in extrophy of the bladder, has been the subject of unlimited discussion. Peterson proves conclusively that placing the ureters in the rectum is an operation not only accompanied by a high mortality, but that in very rare cases does the patient afterwards escape an infection of the kidney through the transplanted ureters. In the experiments on dogs this sequel to the operation was nearly universal. He has shown that hydronephrosis is not an infrequent result of the operation because of constriction of the ureter by the sutures, and hence the point is made that the sutures should only pass through the peritoneum and fat about the ureter. Peterson maintains that the operation of introducing either one or both ureters into the bowel is an unjustifiable operation unless the trigonum of the bladder with the ureteral orifices is also transplanted. The technique of the operation is excellently illustrated in Peterson's article. Even with transplantation of the trigonum infection of the kidney from the bowel may take place. That the rectum tolerates the presence of urine and that a patient with the ureters emptying into the rectum can remain moderately comfortable, are questions long since settled. The very few cases on record in which the patient has escaped infection of the kidneys after the introduction of the ureters into the rectum without their vesical orifices, must convince every thoughtful surgeon of the wise conclusion reached by Peterson regarding the advisability of this procedure.

The Prevention of Blindness.—While the medical profession is striving with remarkable pertinacity for legislation to prevent the dissemination of infectious diseases, it appears to be almost oblivious to the ravages caused by ophthalmia neonatorum. While the question regarding the licensing of prostitution is being argued to a remarkable degree, the fact is lost sight of that one of the gravest sequels of prostitution is the blindness caused in the newborn by infected mothers. While the duties and privileges of midwives are being considered, but little attention is paid to instituting a compulsory prophylaxis which midwives could carry out in labor cases. The medical profession is indebted to Dr. Lucien Howe, of Buffalo, N. Y., who perhaps has done more for the adoption of laws governing this subject than any other man in the United States. At the meeting of the American Academy of Medicine, held in Jefferson, N. H., August 30, 1894, he presented a paper entitled "The Present Condition of Legislation for the Prevention of Blindness." It was the State of New York that made the first effort in this country to obtain a law in this direction, Maine, Rhode Island, Minnesota, Ohio and Maryland soon following. While the prophylaxis of ophthalmia neonatorum should be a part of obstetrical routine, it is frequently neglected by some hasty and careless obstetricians. Howe (*Crede's Method for the Prevention of Purulent Ophthalmia of Infancy in Public Institutions*) states that previous to the introduction of Crede's method, the records of over 17,000 births tabulated by thirteen observers, showed that over 9% of the the children developed ophthalmia neonatorum, and that after the introduction of this prophylactic measure the reports of over 24,000 births, tabulated by 31 observers, showed only .65%. It is true that many women are not infected at the time of childbirth, but legislation is not instituted for individuals, but for the protection of the community. Up to this time legislation on this subject has been for the purpose of compelling midwives, nurses and persons other than legally qualified physicians, to report a case where there is a swelling, reddening or discharge of pus from the eye.

The act passed by the State of Ohio may be taken as an illustration.

Section 1. Should one or both eyes of an infant become inflamed or swollen, or show any unnatural discharge at any time within ten (10) days after its birth, it shall be the duty of the midwife, nurse, or relative having charge of such infant to report in writing within six (6) hours to the physician in attendance upon the family, or, in the absence of an attending physician, to the health officer of the city, village or township in which the infant is living at the time, or, and case there is no such officer, to some practitioner of medicine legally qualified to practice in the State of Ohio, the fact that such inflammation, swelling or unnatural discharge exists.

Section 2. Any failure to comply with the provisions of this act shall be punishable by a fine of not less than

ten dollars (\$10.00) nor more than one hundred dollars (\$100.00) or imprisonment for not less than thirty (30) days, nor more than six (6) months, or both fine and imprisonment.

There have been very few convictions, or even prosecutions, for violation of this and similar laws. For this reason alone its value is quite limited. It should be the duty of every State not only to enforce the reporting of suspicious cases, but to institute measures for prophylaxis. It would be well for the profession to inform the laity in all cases where there is the slightest suspicion of contamination, that the instillation of nitrate of silver is to a great degree a preventive measure in ophthalmia neonatorum. In this manner all persons would be invested with a right which for their own protection they would attempt to enforce, thereby indirectly influencing the attending physician, the midwife, or the nurse. It is furthermore the duty of every State, so far as it is in its power, to enforce the employment of recognized prophylactic measures in the newborn. Again and again some medical man has assumed the leadership and tried to prevent the catastrophes resulting from cases of ophthalmia neonatorum by invoking legislation for its prevention. A great many not only become burdens to themselves, but burdens and an expense to the State in which they live, and for this reason, if for no other, it is high time that something should be done. "There are none so blind as those who will not see."

Objectionable Names for Institutions.—The choice of a name for an institution designed primarily for the relief of suffering, or for developing arrested mentality in children, is one upon which very much depends. It is rather more than sentiment which has so often prompted objections to such titles as Home for Incurables, Home for Consumptives, Cancer Hospital, Institute for the Feeble Minded, and even (as recently established in England) a Hospital for the Dying. There is something of pathos in the thought of a man digging the grave in which his bones will rest—there is a gross violation of the delicacy that is born of the broad spirit of humanitarianism, in the thought of tagging a man's remaining days with the stigma of the malady from which he suffers. Every physician well knows the truth of the lines:

"The wretch condemned with life to part,
Still, still on hope relies,
And every pang that rends the heart
Bids expectation rise."

It behooves us to champion the changing of these objectionable names of institutions. Let us select something which shall not typify so ruthlessly the blasted lives, or undeveloped faculties of the un-

fortunates entrusted to our care. We recognize fully the value of the element of suggestion in bettering the physical processes through the mental, and we know full well how a patient deprived of hope will quickly wane and die:

"Hope, dead, lives nevermore,
No, not in Heaven."

The objects and aims of such institutions are by no means furthered by this method of designation. Rather do they become places to be dreaded and shunned. It may be urged in defense of these titles that after all a name stands for little; that the patients will know soon enough the true import of their disease and their surroundings. But how much better the late Dr. J. M. DaCosta expressed the thought in bequeathing a sum of money to the Pennsylvania Hospital for the endowment of a ward for cases "now deemed incurable." The avenue of hope is still left open. Every effort in the direction of eradicating the significance of hopelessness in these cases must be regarded in the light of removing the fetters of apparent banishment and ostracism.

Cellular Poisons or Cytotoxins.—The great Virchow showed a prophetic instinct when he formulated his theory of cellular pathology. Each organ represents a community of cells; each cell is the ultimate unit, possessing in a large measure its own individuality. It has its own secretion and excretion; it lives, develops, reproduces itself and dies. When a large number of such cells, constituting an organ, become diseased, the entire community suffers, while death of the majority of cells terminates the life of the organ, and if the latter is essential to life, also that of the organism. All physiological functions, as well as pathological alterations, therefore, reside primarily in the cell. In the course of its physiological activity the cell produces poisons (toxins) and substances which neutralize the latter (antitoxins). The toxins, on the other hand, may be harmless to the cell which secretes them, but destructive to the life of cells of other organs or of the same organ in other species of animals, like, for instance, the insect-sting or snake-venom. These facts, of such great importance to the future progress of medicine, are being elucidated by remarkable researches along biological lines. Metchnikoff, to whom we owe our knowledge of phagocytosis, has contributed to the *Russki Archiv Patholog. Khimichesk. y Meditsiny i Bacteriologii* (February, 1901), a paper of most absorbing interest. In it he reviews the progress made in the study of cell-toxins, especially with reference to hemolysis, or the destruction of the red blood-corpuscles of one species of animals by the serum of another. The substance which destroys the blood-corpuscles, or

hemotoxin, consists of two distinct bodies: One, an alexin called by Metchnikoff, *cytase*, is unstable and is destroyed by a temperature of 55-56 C.; the other, *fixator*, withstands a temperature not higher than 65-68 C. The former is found in the serum of any animal; the latter only in the serum of those which have received injections of blood (active serum). In order that the serum of an animal of one species may destroy the red blood-corpuscles of that of another a combination of both *cytase* and *fixator* must be present. Neither alone is capable of dissolving the red blood-corpuscles. To determine the source and distribution of the hemotoxin. Metchnikoff conducted the following experiments: He injected defibrinated blood of a goose into the abdominal cavity of a guinea pig. The red blood corpuscles were at once seized by the mononuclear leukocytes and digested by the ferments secreted by the latter. The analogy between this intercellular digestion and hemolysis is so close that it lead to the conclusion that hemotoxin is the product of phagocytes excreted into the serum. While the *fixator* is circulating freely in the plasma the *cytase* remains within the living phagocytes. But when the leukocytes are by some means, as by the injection of fluids, seriously injured, the *cytase* is released and also circulates in the plasma. The combination of the two constitutes the hemotoxin. The latter, therefore, may be looked upon as the digestive ferment of the phagocytes alone. Any of the other cells produce substances which are toxic. The injection of spermatozoa of one animal into the serum of another is followed by the formation of the spermatoxin, which is identical both in its action on the spermatozoa and composition to hemotoxin. Leukotoxin, a substance which destroys the leukocytes, was prepared by Metchnikoff, Dellsen, Funk and others. Von Dungern obtained, by injecting into guinea pigs the mucous membrane of the trachea of a bull, a serum which destroyed the motion of the cilia of ciliated epithelium. Lindeman, working in Metchnikoff's laboratory, injected into guinea pigs part of the mucous membrane of the result that he obtained a serum capable of causing albuminuria and acute nephritis when injected into rabbits.

Nerve toxins have also been produced although with less constant results. So far experiments have been conducted mostly with heterocytoxins, i.e. those produced by injecting the cells of one species of animals into those of another. Further experiments, however, prove that the organism is also capable of producing autotoxins. The reason the organism is not poisoned under normal conditions is explained by Metchnikoff by the following hypothesis: As long as the organism is healthy the

cytase remains enclosed within the leukocytes, but as soon as the latter are injured by some pathological alteration, the *cytase* is released, combines with the *fixator* circulating in the blood, and autointoxication results. It has further been demonstrated that by a process of gradual immunization it is possible to produce specific anticytotoxins. In these Metchnikoff sees the future possibility of not only curing various degenerative changes produced by the toxins, but actually preventing them. Among the conditions to be benefited in this millenium he includes senile degenerations and atrophies.

Clinical Study of Deciduoma Malignum.—G. Metoz, (*Gaz. Heb. de Med. et de Chirurg.*, March 10, 1901, 48 me. Année, No. 20.) (Paris Thesis.) A noticeable feature in the etiology of **deciduoma malignum** is that the tumor always follows pregnancy, either after normal labor or after abortion. The tumor may develop, as a rule, from 4 to 8 months after delivery. Women attacked with the disease are usually young, the usual age being between 26 and 40 years. Hydatiform mole seems to be an etiological factor in the production of the tumor, 48 cases out of 98 show this condition preceding the development of the tumor. In the case of deciduoma malignum, as in epithelioma of the uterus the tumor often reaches its full development before giving rise to symptoms. When the growth has reached a certain size so that fungous masses without consistency are developed, intense hemorrhages appear. This form of development belongs particularly to that form of deciduoma which follows abortion, or normal labor, and does not apply to those cases of deciduoma that follow extrauterine pregnancy. Uterine hemorrhage is the first symptom of the disease and is due to the involvement and the destruction of the vessels by the vegetating masses. The most important characteristic of the hemorrhages is their extraordinary resistance to all kinds of treatment. When the tumor follows the molar pregnancy the uterus is markedly increased in volume; when it follows abortion or normal labor, the uterus hardly exceeds in size that of 3 months pregnancy. The tumor is usually smooth and regular. On vaginal examination the os is sometimes partly open and sometimes normal. The uterine cavity presents a tumor that projects but little beyond the surface and that is sometimes pedunculated. A little later in the disease metastases appear, which may involve all the organs. Among the seats of these metastases, the vagina seems to be one of the most common. Pulmonary metastases are common and are usually found at the base or at the apex of the lung. Patients thus attacked present symptoms similar to those of patients suffering from chronic bronchitis. Examination of the sputum reveals nothing characteristic. Cachexia appears early. When hemorrhages appear after a patient has expelled an hydatiform mole the clinician ought to think of deciduoma at once. Hemorrhagic metritis and fibroma produce menorrhagia and menstrual disorders accompanied by leucorrea but never such a profuse flow of blood as accompanies deciduoma malignum. Vaginal hysterectomy is the proper treatment of the condition. [J. M. S.]

A Rare Case of Enteroliths.—E. M. Schvalbe (*Medicinskoje Obozrenie*, March, 1901) calls attention to the rarity of true enteroliths in man. In the Russian literature only one case is reported. He reports a case of a woman 68 years old who was admitted to the hospital suffering from intestinal occlusion and general peritonitis. She died 24 hours later. An autopsy revealed the presence of a white chalky fluid in the stomach, while the intestines were filled with large and small stones weighing in the aggregate 710 grms. (the largest stone weighed 34 grms). A chemical analysis of these enteroliths showed them to consist of carbonate of lime with an admixture of sand. It was subsequently learned from the the relatives that the woman was in the habit for the past few years of her life of ingesting large quantities of chalk or sand. [A. R.]

American News and Notes.

PHILADELPHIA NEWS.

College of Physicians of Philadelphia.—Section on Ophthalmology.—Meeting, April 16, 1901. Dr. Wm. Thomson, Chairman, presiding.

Dr. C. A. Veasey exhibited a male patient, 26 years of age with **Right Oculomotor Paralysis and Left Trifacial Paralysis**, involving both the sensory and motor tracts, together with some impairment of the right knee-jerk. The paralyzes were complete, and had been preceded by considerable ciliary pain, described as being behind the eye-balls. At the time of the appearance of the paralyzes there was some difficulty in passing the urine, a soreness and "pulling" behind the knees, which made walking painful, considerable vertigo, and some headache, though the last was by no means pronounced. There had also been slight staggering at times. The case was thought to be one of cerebro-spinal syphilis with meningeal involvement, probably most marked at the base, in the interpeduncular space, and over the pons.

Dr. Geo. C. Harlan exhibited a case of **Abscess of the Orbit from Disease of the Ethmoid; Curetting through the Orbit and Drainage through the Nose**. The patient had had nasal catarrh for more than a year, with caries of the turbinate bone.

Dr. G. C. Harlan called attention to a method of performing **Iridectomy in Case of Obliteration of the Anterior Chamber**, which was described by Gayet at the meeting of the French Ophthalmological Society in 1884. After fixing the eye with the double fixation forceps, Gayet makes a minute incision into the periphery of the anterior chamber with the ordinary scarificator by sawing movements, enlarging the incision with blunt scissors. Dr. Harlan had found this method of operating very useful recently in a case of chronic iritis with increased intraocular tension. He had found a narrow Weber canaliculus knife admirably adapted to enlarging the incision. Its probe point passes readily between the iris and cornea.

Dr. S. Lewis Zeigler presented a case of **Hemophilic Extravasation into the Conjunctiva, Antrum, and Cheek**, associated with habitual constipation.

Dr. Ziegler also reported **Recurring Hemorrhages from the Ciliary Body**, in a woman, aged 26 years, who suffered from habitual constipation.

Dr. John T. Carpenter read a paper on **Purulent Chorioiditis** occurring in a boy, 2 years old, who had suffered from a severe attack of mumps 4 weeks before. There was deep-seated yellowish reflex behind the pupil, and the entire uveal tract became infiltrated with pus.

Dr. H. F. Hansell made some remarks on the **Use of Pilocarpin in the Treatment of Inflammations of the Eye**. He read the history of a number of cases, and gave in detail the method he employs in the treatment. The cases were those of interstitial keratitis, traumatic purulent iritis, vitreous opacities, and retinochoroiditis. In most of the patients the improvement had been most rapid and marked, while in all the treatment had proved beneficial. He expressed regret that the treatment had not been more generally followed in chronic deep-seated ocular inflammations where the usual routine treatment was most prolonged or unsuccessful, and felt sure from his increased experience that many forms of inflammation and of loss of vision could, with few exceptions, be materially improved. The recovery in some of the cases described was most satisfactory. The most striking was that of Case No. 1, of traumatic purulent kerato-iritis, in which the intense injection had decidedly cleared and the large collection of pus in the anterior chamber, altogether disappeared in 24 hours, with complete recovery in one week.

Discussion—Dr. de Schweinitz had secured gratifying results with pilocarpin in the treatment of the same class of cases referred to by Dr. Hansell. He stated that some

nerve specialists placed great reliance upon the drug in toxic insanity after influenza, autointoxication, and similar processes, the brain rapidly clearing after two or three sweats. Apart from its action hypodermatically, he had found pilocarpin or the fluid extract of jaborandi, in small doses by the mouth, to be of value, especially in degeneration of the vitreous. He had never had but twice unpleasant symptoms following the pilocarpin sweating, one a bad attack of pulmonary edema, and the other intense salivation. The persistent nausea that is so common after the use of the drug is usually relieve by small doses of chlorodyne, as suggested by Dr. H. C. Wood. Dr. Shumway had, in one instance, persistent secondary sweating, for which he was compelled to use alcohol bathing. Dr. Hansell said he had never had to employ measures to limit the period of skin action.

Dr. G. E. de Schweinitz reported a case of **Probable Methyl-alcohol Amaurosis, the Pathway of Entrance of the Poison being the Lungs and the Cutaneous Surface**, and reviewed the literature of blindness from this liquid. The man, aged 39, was a varnisher by trade. Two months prior to his amaurosis he had been constantly employed in shell-lacing, and was accustomed to dilute the shellac to the desired thinness with methyl-alcohol. He was therefore almost uninterruptedly during the working hours of this period exposed to the fumes of the wood-spirit, and was also accustomed at the end of his day's work to wash his hands, forearms, and face with the same liquid in order to remove the shellac stains. Dr. de Schweinitz drew particular attention to the dangers which workers in this liquid ran, and thought that they, as well as their employers, should be properly warned. He pointed out the analogy between these dangers and those which were encountered by workers in lead, nitrobenzol, and dinitrobenzol, and how in the last three-named trades all proper precautions were taken to prevent the well-known toxic action of these drugs.

Discussion—Dr. Hansell said that he had examined the man on several occasions. When he first came to the Jefferson Hospital he had double optic neuritis of moderate grade and was totally blind. Under treatment vision improved in each eye so that he was able to go about the streets alone. The improvement was retained for a few weeks and then vision commenced to decline. The diagnosis that was made at the first examination was hemorrhage into the chiasm, and this seemed to be confirmed at later examinations by a well-marked right hemianopsia, distinctly outlined in the left eye and less complete in the right. The optic neuritis gave away rapidly to atrophy. There was no paralysis of any of the ocular muscles.

Dr. Wm. Thomson gave a demonstration of a **New Lantern Test for Detecting Color Blindness**, being aided by a young ophthalmologist who suffered from green blindness, the form of color defect which has been found most difficult to detect by the wool test of Holmgren and its varieties.

Neurological Society.—At the meeting of April 22 Dr. Alfred Gordon exhibited a **Case of tea-intoxication with spinal symptoms**. The patient was a woman of 41 who had drunk as high as 360 ounces of tea per day. She presented the symptoms of combined sclerosis together with hysterical manifestations. Cerebral symptoms were not marked. The possibility of lead poisoning was suggested, this being derived from the coloring of the tea. Dr. J. Chalmers Da Costa exhibited a **case of trichiniasis**. This case, of which only a preliminary report was made, was interesting from several points of view. The affection began in the calf of the right leg during January 1901. The gastrocnemius muscle enlarged and was painful at night. The condition has extended until the thigh is now involved. The muscles are greatly enlarged and dense. There is a history of traumatism on the calf of that leg last August but recovery from the bruise was apparently complete. The patient changed occupation after the injury and began eating pork 4 times a week but denies eating any raw pork, although he has eaten raw beef. Sections of muscle removed

for study shows numerous trichinae. The highest percentage of eosinophilis in the blood was 4% the first count made. Later counts show that the leukocytes have increased from 12,000 to 20,000, but the eosinophiles are less. The case is interesting because of the absence of all the ordinary signs of trichiniasis. Dr. Max Bochroch exhibited a case of chronic arthritis. The patient has a history of 3 attacks of rheumatism. There is now limitation of movement of the back and there is also some rigidity of the shoulder and hip joints. The supra- and infra-spinatus muscles are much atrophied. Drs. William E. Hughes and W. G. Spiller reported a case of severe anemia, with changes in the spinal cord. Post mortem showed sclerosis of the spinal cord but there was no evidence of changes in the vessels the condition probably being due to a toxic material in the blood. Discussion by Drs. Lloyd, Burr and Mills emphasized the point that changes in the vessels are not essential points in the etiology of this condition. Dr. Mills stated that pernicious toxemia is a better term than pernicious anemia. Dr. W. W. Keen reported a case of secondary suture of the posterior interosseous nerve with complete re-establishment of function. The patient was a man of 38 who in August 1900 received an axe wound which severed the posterior interosseous nerve. In November the nerve was exposed, 7mm. removed and the ends approximated. Slight extension of the fingers was possible in 8 days and the improvement afterward was steady. Dr. David Riesman reported a case of intermittent claudication. The patient was a man who had pain, numbness, loss of power of the legs, etc. when he was on the street. A few minutes rest would enable him to proceed again. The etiology of the condition seemed to include only three factors, tobacco, exposure, and mental strain. Nitro glycerine and potassium iodide gave no relief but the patient seems better after the use of the bromides. Strophanthus will be added.

Pennsylvania Hospital.—The Pennsylvania Hospital, termed by its historian, Dr. Thomsa G. Morton, "the Mother of American Hospitals," will celebrate on May 11 next the 150th anniversary of its establishment. It was founded by the Assembly of the Province of Pennsylvania in 1751, in response to a petition in the handwriting of Benjamin Franklin, which was drawn up at the suggestion of Thomas Bond. Funds were not plentiful, and it was only on the offer of Drs. Thomas Bond, Lloyd Zachary, and Phineas Bond to give their services for three years that a modest grant of £2,000 was made, to be supplemented by a like amount from private subscription. Since its inception, to quote from the *Philadelphia Ledger*, "the hospital has either led or kept pace with advancements in surgery and medicine. It was the first to introduce clinical teaching in this country, the first bedside instruction in medicine being given by Dr. Bond. It was the pioneer in this country in caring for the insane, and led the world in evolving and perfecting the humane and rational treatment of those suffering from disordered minds." Another circumstance that gives it fame is that it is the one great hospital in the country that has cared for wounded soldiers of the colonial and Revolutionary wars, the War of 1812, the Mexican war, the civil war, and the Spanish-American war.

Philadelphia County Medical Society.—A regular meeting of the Society was held April 24, the President, Dr. George Erety Shoemaker, occupying the chair.

Dr. John B. Roberts exhibited 2 cases: (1) Insertion of artificial vitreous after evisceration of the eyeball; (2) Rhinoplasty after loss of the end of the nose. The further program of the evening was a symposium on Diphtheria. Dr. J. D. Steele read a paper on *The present aspect of the Antitoxin Treatment of Diphtheria*. Dr. Steele quoted figures from various societies and compilers showing the diminished mortality from diphtheria since the introduction of the antitoxin treatment. The results vary according to the promptness with which the antitoxin is administered, the mortality being from 3 to 5% in cases where injections are begun on the first day and increasing each day thereafter until the average of about 16% is reached. A case was cited to show the protection afforded the myocardium by early injection of antitoxin. A girl who had a badly damaged heart as shown by multiple murmurs was taken with diphtheria. On the evening of the second day 1250 cc. of antitoxin in 2 doses was administered. The girl went on to rapid convalescence with

no apparent involvement of the heart by the disease. Paralyzes following diphtheria are not materially reduced by the use of antitoxin. As to the immunizing power of antitoxin an occurrence at the Presbyterian Hospital was cited. Three or 4 cases of diphtheria occurred in the children's ward. The remaining children and the nurses were given immunizing doses of antitoxin. Cultures were soon afterward made from the throats of 17 patients and 2 nurses. In 5 patients and 1 nurse the Klebs-Löffler bacillus was found. A later test from 10 patients and 4 nurses showed the bacillus in 3 patients and 3 nurses. Yet there was no evidence of clinical diphtheria in any of these cases. To prevent the spread of diphtheria the immunizing power of antitoxin should always be employed in addition to isolation and the making of cultures from the throat to determine where infection exists. A successful method of removing the bacilli from the throat is to swab on 3 successive days with a solution of silver nitrate, 1 drachm to the ounce. Statistics of the mortality from diphtheria in Chicago, New York, Boston, and Philadelphia were given. These showed Philadelphia to have a mortality considerably higher than either of the other cities mentioned, the general city history not being at all satisfactory in this respect. The conclusion of the paper was that the curative and immunizing power of diphtheria antitoxin had greatly reduced the mortality from diphtheria and that it should be promptly used for the treatment and prevention of that disease. It has probably not been employed in Philadelphia with the energy shown in the other cities named, with the result of a higher death rate in the former city.

The discussion on the subject of the evening was opened by Dr. A. C. Abbott, who spoke on *The Bacteriology of Diphtheria*. Dr. Abbott said that many physicians had difficulty in understanding why some cases of diphtheria did not have severe clinical symptoms and yet the bacteriologist would tell them that virulent germs were present in the throat of the patient. The speaker explained this by saying that variety in diphtheria was not more remarkable than in other diseases. This is probably due not so much to the bacteria as to the resistance of the individual. Then again there are variations in the virulence of the bacteria, but it is true that virulent bacilli are as often found in mild cases as in severe cases clinically. The pseudodiphtheria bacillus was once differentiated by its pathogenic powers from the bacillus of diphtheria, the guinea pig test being the standard. Now the term is confined to those which resemble the true bacillus but can be differentiated by other methods. Nasal cases with no clinical manifestations should be carefully looked after. Dr. Richard Pearce exhibited lantern slides showing *The Pathology of Diphtheria*. The slides illustrated the changes taking place in the heart and kidneys when those organs are involved. Dr. Joseph McFarland spoke on *The mode of operation of antitoxins*. Two theories are held regarding this. One is that they stimulate vital reaction in the organism against the toxins present. A second, held by the Germans, is that there is a chemical reaction between the toxin and antitoxin. It is impossible at the present time to say which is correct but indications point to the latter as the more probable. The various toxin and antitoxin reactions are partly specific. In some instances where half a dozen or more poisons are similar, as snake venoms, one antitoxin does for all and is not specific for any one. Diphtheria toxin is the only one of its kind, hence diphtheria antitoxin is the only one that will counteract it. The chemical effect of various antitoxins and their effects on toxins and tissues was discussed at length. Dr. M. Howard Fussell said that as an early practitioner he had looked for the typical textbook cases of diphtheria but he failed to find them. Neither the constitutional nor local symptoms are characteristic. It is said that in diphtheria the exudate is removed with difficulty and leaves a bleeding surface. But this is found in other infections. Slight complaining by the patient is more characteristic of diphtheria than of other infections. The only positive diagnosis is that made from throat inoculations but while waiting for the result of the bacteriological investigation antitoxin should be given. Dr. Fussell rarely uses more than 1000 units at a dose, but repeats it unless improvement is early and rapid. Applications to the throat are made or not made according to the individual. Deaths have occurred as a result of persistently making applications to nervous struggling children. Simple alkaline solutions in Dr. Fussell's experience. He always gives mer-

cury and iron. Dr. Packard said that he believed the high mortality of Philadelphia was due to the fact that many mild cases of diphtheria were not reported as such because of placarding houses, etc.

The Pennsylvania Society for the Prevention of Tuberculosis.—The annual meeting of the Pennsylvania Society for the Prevention of Tuberculosis was held in Philadelphia on April 11, 1901. The secretary reported that during the past year the society had published and distributed over 30,000 of its tracts and had used constant efforts to induce those in influential positions to aid in preventing the spread of the disease. The Society used its influence to secure the new rule of the Bureau of Health by which cases of tuberculosis are to be registered in Philadelphia. It has published a leaflet on the subject of Registration. Its publications have been sent all over the United States in response to many requests. Its officers have endorsed and assisted the Free Hospital for Poor Consumptives of Philadelphia and have gone to the New Jersey Legislature to assist in pleading for a State Hospital for consumptives in that State. The society has made strong efforts to show the need of a State hospital for consumptives in Pennsylvania.

Historical Club of the Department of Medicine of the University of Pennsylvania.—The first stated meeting of this club was held at the office of Dr. Charles A. Oliver, on Wednesday evening, the seventeenth of April, 1901. Dr. Oliver presiding.

The club which was organized in March, 1901, has for its objects "the study of the history, with the collection, presentation and publication of dates relating to the Department of Medicine of the University of Pennsylvania." Besides original research into the past history of the Department with the periodic publication of a series of Proceedings, and the getting of a special library, it is intended that the club shall collect historic portraits, pictures, engravings, furniture, instruments, books, certificates, etc., to be placed in appropriate University quarters. After an informal discussion in reference to the collection and disposition of some of the diplomas of the early graduating classes of the department, the original minutes of the organization meeting of the Alumni Society of the Medical Department were read and deposited among the archives of the Club by the presiding officer of the evening. Arrangements were made to present a series of papers on the Graduates of the Medical Department who served during the Revolutionary War at the next meeting.

Pathological Society of Philadelphia.—The annual Conversational Meeting of the Society was held April 25. The address was delivered by Dr. Charles Wardell Stiles, of Washington, his subject being "*Trichinella spiralis*, Trichinosis, and Trichina Inspection—A Zoological Study in Public Medicine." Dr. Stiles spoke first of Dr. Leidy, of Philadelphia, who in 1847 discovered the trichina in ham from which he was preparing a sandwich. The parasite had been discovered in man in 1835, but Dr. Leidy's discovery was the foundation of the knowledge of its life history. Dr. Stiles then reviewed the trouble between the United States and Germany regarding pork sent from this country. The system of inspection was detailed. During the years 1860-98 there were 14,824 cases of trichinosis in Germany with 831 deaths. The German inspection of pork includes the diaphragm, poas muscles, and the tongue. In 1896 there were in Prussia 27,602 paid microscopists engaged in meat inspection. This would mean nearly 65,000 for the United States were such a system inaugurated. Comparing the cost for the two countries it would cost this country between 3 and 4 millions of dollars annually. Dr. Stiles then compared the American curing process with German inspection as a means of rendering pork safe to eat. A summary of the cases in Germany from 1881 to 1898 shows that 3388 cases and 132 deaths, or 53% of all cases and 41% of all deaths were due to faults of German inspection methods. Inspection creates a false security and dependence had better be placed on curing and cooking. During the exclusion of American pork from Germany there were 4093 cases of trichinosis with 274 deaths in that country. Since readmission of American pork there have been 1093 cases and 27 deaths. Statistics show that there have actually been less cases during the admission of

American pork than during its exclusion. Since its readmission there has been greater vigilance by the authorities and 90% of all cases have been traced to their source. Not one case has been traced to American pork, thus fully proving its sanitary quality. The German inspection is no more valuable than the curing methods here and the government should not accede to the few and establish a system of inspection with its great cost.

In reply to several questions Dr. Stiles stated that the ordinary pickling methods in use here would destroy all trichinae in 3 months. The so-called "embalming" of meat, made famous by the late war, is one of the greatest advances in hygiene ever made in this country. It enables the process of curing to proceed from the interior of the meat outward at the same time that it is extending inward from the immersion fluid. The Government here takes no part in the curing of meat for home consumption, but export meat must have been in the pickle for a certain length of time. The government takes no stand in regard to the chemicals used by the packers. There is no inspection here for local trade but interstate meat is inspected for tuberculosis, hog cholera, etc., but not for trichinae. Pork in general contains trichinae to the amount of 2%.

Obituary.—Dr. William Jekyll Reichmann, at Algiers, Africa, on March 29.—Dr. Joshua Kenedy, at Scales Mound, Ill., on April 20.—Dr. Thomas H. Buckler, at Baltimore, Md., on April 20, aged 90 years.—Dr. Lewis R. Kirk, at Rising Sun, Md., on April 19, aged 69 years.—Dr. Edward M. Schaeffer, at Baltimore, Md., on April 21, aged 45 years.—Dr. J. H. Woodburn, at Indianapolis, Ind., on April 23.—Dr. Joseph S. Carradine, at East Orange, N. Y., on April 23.—Dr. Joseph S. Carradine, at East Orange, N. Y., on April 23.—Dr. Edwin F. Morris, at Birmingham, Ala., on April 23, aged 36 years.—Dr. Horatio Guzman, at Washington, D. C., on April 23, aged 50 years.

Vital Statistics of Philadelphia for the week ending April 27, 1901:

Total mortality	485
Cases.Deaths.	
Inflammation of appendix 2, bladder 1, brain 11, bronchi 7, kidneys 23, lungs 73, pericardium 1, peritoneum 5, pleura 1, stomach and bowels 36	140
Marasmus 10, debility 8, inanition 11	29
Tuberculosis of the lungs	73
Apoplexy 13, paralysis 8	21
Heart-disease of 34, fatty degeneration of 4, neuritis of 2	40
Uremia 11, diabetes 4, Bright's disease 13	28
Carcinoma of bladder 1, breast 4, stomach 4, pelvic 1, face 1, kidney 1, rectum 1, throat 1	14
Convulsions	14
Diphtheria	6
Brain-abscess of 2, congestion of 1, softening of 3, tumor of 1	7
Typhoid fever	7
Old age	6
Cyanosis	4
Scarlet fever	8
Atheroma 1, alcoholism 2, asthma 3, anemia 1, burns and scalds 4, casualties 13, congestion of the lungs 5, carbuncle 1, cirrhosis of the liver 3, consumption of the bowels 1, croup, membranous 1, dropsy, abdominal 2, erysipelas 4, fever, gastric 1, remittent 1, gall stones 1, gangrene 3, hernia 1, influenza 6, jaundice 2, locomotor ataxia 1, leukemia 1, obstruction of the bowels 2, edemia of lungs 2, rheumatism 5, retention urine 1, sclerosis, arterial 3, septicemia 4, small-pox 1, sarcoma parotidgland 1, sarcoma liver 1, stricture of esophagus 1, suicide 2, teething 1, tetanus 1, tumor, neck 1, stomach 1, whooping cough 3, wounds, gunshot 1.	

NEW ENGLAND.

Death of Dr. George Cogswell.—Dr. George Cogswell, 93, one of the oldest residents of Haverhill, died April 11th, at his residence in Bradford district. He was born in Atkinson, N. H., the son of Dr. William Cogswell, who was chief surgeon at West Point during the Revolution.

Death of Dr. Fred J. Brockway.—Dr. Fred J. Brockway died at the Brattleboro retreat April 21st, after an illness of several months. Dr. Brockway was born in South Sutton, N. H., in 1860. During his boyhood he attended the district schools, and prepared for college at the Tilton seminary, where he graduated. Soon after he entered Yale, where he received the degree of A. B. in 1882, after which he taught school in Stamford, Ct., for two years, when he entered the college for physicians and surgeons in New York, where he graduated in 1887, being class president and one of the honor men. After graduation he received an appointment in the surgical department of Roosevelt hospital, which position he held for a period of two years, retiring to accept the position of resident surgeon at Johns Hopkins hospital, Baltimore, being the first resident surgeon. In the fall of 1890 he returned to New York as lecturer and demonstrator of anatomy at the college of physicians and surgeons, and later was appointed secretary of the faculty, which position he held until the date of his last illness. He was a member of Omega society, life member of the New England society, member of the academy of medicine, West End medical society, county medical society, American association of anatomists, academy of science, American museum of natural history, New York athletic club and the Johns Hopkins resident association. He was the author of "Chemistry and Physics," "Compend of Anatomy." He wrote the chapter on viscera for the last edition of "Gray's Anatomy," revised "Nancree's Anatomy," and when stricken by illness was preparing a work on anatomy, which Dr. W. H. Rockwell, Jr., formerly of Brattleboro, will complete. In addition to these he wrote several monographs on anatomical subjects. When stricken down he was entering upon a most flattering professional career, his gentle and lovable nature having won for him a host of friends among his scientific brethren. He seldom took a vacation, but, on the contrary, worked almost incessantly, and the final breakdown resulted largely from ceaseless devotion to his profession.

A Case of "Folie Communique."—According to the *Journal of Mental and Nervous Diseases*, a family consisting of two brothers and a sister, living in New Haven, Conn., recently all became insane within one week. The sister became ill and acute mania quickly developed. A few days later the older brother suddenly lost his reason and began to rave, attacking the physician who was called in. Two days after this the younger brother developed acute melancholia. Although the family was considered well-to-do, no property has been found, and they will become charges of the State Hospital for the Insane.

WESTERN STATES.

Appointment.—Dr. Reuben Peterson of Chicago has been appointed to the Bates professorship of the diseases of women in Michigan University, to succeed Dr. J. N. Martin.

Dr. John Bassian.—Dr. John Bassian died on April 18th at Fresno, Cal., aged 70 years. He was a native of Turkey, an eccentric man, one of profound learning and one who had at his fingers' ends all the languages of the Mediterranean and of the Levant. He was the father of Alexia Bassian, who is well known in the musical world. She once sang before the Prince of Wales and exhibits a solitaire and diamond cluster ring as a gift and memento of the occasion. Dr. Bassian served as a surgeon in the Turkish army and was special court physician to the Sultan.

Cancer Increasing.—Late statistics from all points tend to sustain the claim of many American observers that cancer is increasing in frequency to an alarming extent. In Moscow the number of reported cases has doubled

since 1880, while in Russia (according to Heymann) the rate of mortality from carcinoma is four times as great as in 1877.

Insane from Religious Excitement.—In the report of the Central Hospital for the Insane, at Indianapolis, Ind., the superintendent classifies the causes which led to the insanity of the persons committed during the year, and of the five hundred and seven nearly ten per cent. were made insane by reason of religious excitement. The report says that none of the latter were affected by hereditary insanity.

Appointment.—Dr. A. W. Barber, of Cheyenne, Wyo., was recently appointed secretary of the State Board of Health.

Appointment.—Dr. George B. Storey, of Portland, Oregon, who has been acting as assistant surgeon in the army in the Philippines since the outbreak of the war with Spain, has been appointed assistant surgeon in the regular army, with the rank of first lieutenant.

Western Ophthalmologic and Oto-Laryngologic Association.—At the Sixth annual meeting of the Western Ophthalmologic and Oto-Laryngologic Association held in Cincinnati, Ohio, April 11th and 12th, the following officers were elected: Dr. C. R. Holmes, Cincinnati, O., President; Dr. W. L. Dayton, Lincoln, Neb., first vice-president; Dr. J. O. Stillson, Indianapolis, Ind., second vice-president; Dr. H. W. Loeb, St. Louis, Mo., third vice-president; Dr. O. J. Stein, 100 State street, Chicago, Ill., treasurer; Dr. William L. Ballenger, 100 State street, Chicago, secretary. At the meeting in Cincinnati the scientific program was of very high grade. Forty new members were elected.

SOUTHERN STATES.

An Interesting Medico-Legal Point.—A case of a great deal of interest for medico-legal experts has recently occurred in Christiansburg, Va. It appears that a woman was given an overdose of some narcotic, presumably opium in some form, by her husband; he notified some of the neighbors that she was dead, but did not allow them in the room; she was buried on the second day. Suspicions having been aroused, the body was disinterred and it was found that she had given birth to an infant, she being near her expected time of confinement. This fact at once gave rise to the rumor that she was put in her coffin alive and in her struggles to extricate herself, gave birth to the child.

Blackmailers Foiled.—Dr. J. H. Hargram, of Petersburg, Va., has caused the arrest of three men in his city, who came to his office and charged him with wronging the daughter of one of them and demanded at the point of a pistol that he should pay \$1000. The doctor finding himself at a disadvantage said he had no money, but would go out and fix up a note. He was allowed to go and went at once to a magistrate and swore out a warrant against the intruders.

In Active Practice for 57 Years.—Dr. James McCaw, of Richmond, Va., on the occasion of his retirement from the medical profession was recently presented with a silver bowl by his medical friends.

Decision in Favor of Vaccination.—In a test case made in Austin, Texas, the Attorney General has decided that school trustees have the right to require certificate of successful vaccination of all children making application to be admitted to schools.

Dr. Henry Bryon McKellops.—Dr. Henry Bryon McKellops died April 23, at St. Louis, at the age of seventy-eight years. He had an international reputation as an authority on all matters pertaining to dentistry and dental surgery. He was born in Salina, near Syracuse, N. Y. In 1855 the Ohio Dental College conferred on him the degree of Doctor of Dental surgery; in 1865 he organized the Missouri Dental Association, and in 1877 was elected President of the St. Louis Dental Association. In 1868 he was chosen President of the American Dentists' Association, and later of the Southern Dental Association, and the Mississippi Valley Dental Society. Dr. McKellops was commended for gallantry during the Mexican war, commanding Morgan's Riflemen.

Association of American Medical Colleges.—The next regular meeting of this association will be held at the Hotel Ryan, St. Paul, Minn., Monday June 3d, 1901. It will consist of two sessions, an educational session and a business session. The educational session will be opened at 2 P. M., by the President's address, followed by several papers of medical pedagogic interest. To this session all persons interested in medical education are respectfully invited. The representatives and associates of the Association of Southern Medical Colleges have received a special invitation. The members of the Confederation of State Examining and Licensing Boards are also invited. There will also be an exhibition of work done in medical colleges. At 8 P. M. the business session will be held at which the amendments to the Constitution proposed by several colleges will be considered. The report of the judicial council, the election of members and the election of officers for the succeeding year will close the program.

Retires as Rear Admiral.—Medical Director Walter K. Schofield, of this city, goes on the United States Navy retired list, still retaining the title of medical director, however, but with the rank of rear-admiral added. Director Schofield has been in the service for forty years. He was born in Connecticut in 1839. At the outbreak of the Civil War in 1861 he entered the medical corps as assistant surgeon and was with Farragut's fleet during many of the most memorable engagements of the rebellion, serving off Charleston and later off the coast of Florida. He served a year in the hospital in New Orleans; afterward he was transferred to the Norfolk Hospital, where he was stationed when peace was declared. Director Schofield has a host of friends among naval veterans, who all attest to his skill as a surgeon. After the war Director Schofield was stationed in China, Japan, South America, Africa and Europe. During those years he passed through all the grades of the medical branch of the service, ending with the title of medical director. Six years ago he was transferred to Philadelphia, during which time he has been serving with the Pennsylvania Marine District recruiting stations.

Havana Improving.—Major W. C. Gorgas, Chief Sanitary Officer at Havana, accompanies a tabulated report of the vital statistics of Havana for March with a letter calling attention to the fact that the death rate (26.28) is lower than that of any March since 1889. There were only four cases and one death from yellow fever, and since March 23 the city has been free from the disease. Major Gorgas ascribes this condition as partly due to the systematic and extensive way in which the sanitary officers have been killing the mosquitoes during the month over a wide area. The condition with regard to smallpox is equally satisfactory, and Havana has not had a case since last August, although it has been breaking out in all parts of the United States.

Leprosy in Canary Islands.—The existence of about 200 lepers on the Island of Teneriffe, Canary Island, has been officially reported at Washington by the United States Consul. At Santa Cruz de Teneriffe, the capital, there are 22 lepers, 15 of whom are men, and there are also some children. There are in addition living at the same place about 200 people. Officially it is not recognized that leprosy exists on these islands.

CANADA.

(From Our Special Correspondent.)

Deaths in Ontario for the month of March, according to the bulletin of the Ontario Provincial Board of Health totaled 2,411 as compared with 2,480 for February and 2,330 for the corresponding month in 1900. This increase represents more than appears in the figures for as 96 per cent of the population reported last year the returns for this year are from only 87 per cent. The following are the deaths from the principal contagious diseases in March: Scarlet fever, 29; diphtheria, 46; measles, 12; whooping cough, 6; typhoid, 21; consumption, 188. Diphtheria shows an increase over 1900 when in the same month only 34 deaths occurred. The Registrar-General is of the opinion that better attention to registration has something to do with the increases in the death returns for the past months. A Lecture on the Life of Huxley

was given before the Canadian Institute on Saturday evening last, the 20th inst. by Dr. A. B. MacCallum, professor of physiology in Toronto University. One interesting incident in the life of this eminent scientist of local importance was referred to. Huxley was anxious to marry, and in order to enable him to carry out this project, he applied amongst other places for the vacant chair of natural history in Toronto University. This occurred in the period of "storm and stress" between 1850 and 1855. The post in the University of Toronto had been advertised at £350 per annum with a share of the fees; and while he was applying for this position Professor Tyndall was seeking a chair in the same institution, namely that of mathematics and natural philosophy. Politics were, however, then too strong in the affairs of this university, for although Huxley was the leading scientist, as teacher and investigator in the field of natural history, a brother of the leader of the then government of Ontario carried off the prize against his eminent competitor. It has been stated that it was Huxley's opinions on religious subjects which caused his rejection, but Professor MacCallum states this could not be the truth as it was not until five years later that anything of this character appeared in the writings of this great man. Then, Professor MacCallum says it was worthy of note "that the filling of the position was made the occasion for criticism against the university as a Godless institution on the ground that the successful applicant was a Unitarian in religious belief."

The Executive Committee of the Canadian Association for the Prevention of Tuberculosis met in Ottawa on the afternoon of Saturday the 30th inst. His Excellency, the Governor-General presiding. Dr. E. P. Lachapelle of Montreal was added to the Committee. It was decided to make all the Secretaries of the provincial boards of health corresponding members. The Rev. Dr. Eby, the general secretary of the Association, on request from the Ontario Executive and the Toronto branch was appointed a special organizer and agitator for the next six months in order to carry on a systematic campaign of education throughout the province on the legislation passed one year ago in the provincial parliament referring to municipal sanatoria; and towards this campaign, the central Association voted the sum of \$300. Dr. Eby resigned the general secretaryship and Dr. H. B. Small, the treasurer of the Canadian Medical Association was invited to accept the position.

McGill's Soldiers, the boys who have returned from the South African battlefields were tendered a banquet by the Graduating Society of the University on the evening of Friday, the 19th inst. The South African officers, non-coms., and privates thus honored by their fellow graduates numbered twenty-four and were largely from the medical faculty of the University and included Surgeon-Major Wilson, Surgeon-Major Worthington and Surgeon-Major Fiske. Two were undergraduates of McGill, Trooper Harold Borden and Gunner O'Reilly, both of the medical faculty, were not forgotten by their comrades and many were the eulogiums passed upon their bravery by the different speakers, for they had left their bodies in far South Africa in defence of their country's flag. Both were sons of well-known medical men in Canada, the former being the only son of the Hon. Dr. Borden, Minister of Militia; the latter of Dr. O'Reilly, of Hamilton, Ont.

The Sewage Farm in Montreal which was constructed a little over a year ago at a cost of \$75,000 has proved a dismal failure. At that time the advice of the then city engineer was that a couple of feet of pipes was necessary, one to carry the surface water and the other the sewage proper to the farm, was totally disregarded; and now the filth from the sewer outlets empties itself into the surface of the farm at one end and then rushes out at the other over the intervening country into the Back River without being purified at all. For over a mile there is a slimy trail of filth; and the stench from the raw sewage passing over the surface of the ground is said to be awful and is fast adding another source of disease to the inhabitants of that city. It is so early in the month of May that the sanitary reform. Montreal has just passed through a serious epidemic of scarlet fever, and the approach of warm weather is almost being anticipated on account of the dreadful filthy condition of the city at the present time. Ordinarily, the infant mortality in that city is enormous and the present aspect of affairs seems to give no indication that there will be any abatement in that respect.

The Medical Council of Ontario has just sent out to a number of practitioners throughout the province a circular

letter which will not be very palatable reading to many of them. It costs \$100 to become a licentiate of the College of Physicians and Surgeons of the province of Ontario; and when licensed, the College demands that \$2.00 be an annual fee for registration. Some years ago a rough breeze blew up over this very same fee and there was much feeling in the profession with regard to it, many holding that it was an altogether unnecessary tax, that the College should be able to manage its affairs out of the funds derived from students at their examinations. Now a number of practitioners who have allowed the payment of these \$2.00 annual assessments to drift, have received notices from the official prosecutor of the Medical Council that their names have been erased from the official prosecutor of the Medical Council that their names have been erased from the register and that unless all arrears be paid within thirty days, they will be proceeded against just the same and in the manner pursued in regard to other unregistered practitioners, that is, quacks. No doubt, the affair will create interesting diversion for the prosecutor in that he will be taking his pound of flesh out of the constituents of his employers.

Bishop's College, Montreal, held its annual convocation for the Medical and Dental faculties last week. the chancellor, Dr. John Hamilton, presiding. Dean Campbell of the Medical Faculty presented the annual report of that department of the University, referring in strong terms of the need for larger endowments for that faculty if it were to carry on the work of teaching as successfully as it has done in the past. Especially did the primary chairs require assistance, because it was impossible to have them filled at the present time by men who enjoyed large practices. The year just closed shows an increase in this faculty, and a decrease in the dental, the latter being no doubt due to the additional year, and a more searching preliminary examination. During the past year there were 84 students registered out of which number nine received their M. D. C. Ms that day. Dr. Hyman Lightstone delivered the valedictory for the new M. D.s while Dr. Anglin replied for the faculty.

The Sect of Christian Scientists in Canada, while not large, is said to be growing. The subject has been taken up repeatedly recently in Toronto pulpits and it has received universal condemnation from all denominations. In 1890 they are said to have started with a membership of a score or two; while at the present time they have a membership of over 3,000 and some 5,000 adherents. Thirty-two of their churches exist scattered over all parts of the Dominion, four of these in the cities of Toronto, London, Berlin and Montreal being owned outright, whilst the balance are merely rented. In Toronto, sometimes spoken of as "The Good," there are some 500 of these people, which cannot be said to be very many out of a total population of 230,000.

Smallpox has broken out again in this city and there are now some four or five cases, one of them being a medical man. Throughout the province of Ontario the outlook is improving generally. Very few cases have been reported from old Ontario. The men employed in the lumber camps in the northern part of the province, that known as new Ontario have nearly all left their camps for their homes, and some 5,000 of them have been vaccinated, whilst over 2,000 pieces of baggage have been disinfected at Sudbury, where is situated the smallpox camp. At the present time smallpox exists in fifteen centres west of Sudbury and in thirty centres in old Ontario. At a number of places in different parts of Canada, pupils at the schools are being kept away on account of not submitting to the process of vaccination.

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Hospital Service for the 7 days ended April 25, 1901:

F. W. MEAD, surgeon, Department letter of January 11, 1901, granting Surgeon Mead leave of absence for 60 days, amended so that said leave shall be for 1 month and 24 days—April 19, 1901.
A. H. GLENNAN, surgeon, to proceed to Tallahassee, Florida, for special temporary duty—April 22, 1901.
W. P. MCINTOSH, surgeon, to proceed to Ducktown, Tennessee, for special temporary duty—April 19, 1901.
W. J. PETTUS, surgeon, department letter of January 11, 1901, granting surgeon Pettus leave of absence for 2 months, amended so that said leave shall be for 1 month and 27 days—April 8, 1901.

C. P. WERTENBAKER, passed assistant surgeon, to represent the service at meeting of Texas Medical Association, Galveston, Texas—April 22, 1901.

J. A. NYDEGGER, passed assistant surgeon, to proceed to Cape Charles Venture, Va., for special temporary duty—April 24, 1901.

H. S. MATHEWSON, passed assistant surgeon, to proceed to Ponce and Guayanilla, Porto Rico, for special temporary duty—April 24, 1901.

W. W. KING, assistant surgeon, to proceed to Guayanilla, Porto Rico, for special temporary duty—April 24, 1901.

L. P. GIBSON, acting assistant surgeon, granted leave of absence for 7 days—April 25, 1901.

J. C. RODMAN, acting assistant surgeon, granted leave of absence for 7 days from April 24—April 25, 1901.
MARK H. WATTERS, hospital steward, relieved from duty at Chicago, Illinois, and directed to proceed to St. Louis, Missouri, and report to the Medical Officer in command for duty and assignment to quarters—April 19, 1901.

Changes in the Medical Corps of the Navy, for the week ended April 27:

ASST. SURGEON J. B. DENNIS, detached from the Naval Academy, and ordered to the Chesapeake, May 2.

ASST. SURGEON C. G. SMITH, ordered to the Vermont, April 25.

MEDICAL INSPECTOR F. ROGERS, ordered to the Brooklyn for duty as Fleet Surgeon of the Asiatic Station.

SURGEON W. F. ARNOLD, detached from duty at Olongapo, P. I., and ordered to the New Orleans.

SURGEON C. F. STOKES, ordered to the Cavite Naval Station, to await the Solace.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, U. S. Marine Hospital Service, during the week ended April 26, 1901:

CONTINENTAL EUROPE.

To Investigate Malaria.—Dr. Koch intends, in conjunction with the German Colonial Office, to organize various expeditions into German Africa for the purpose of carrying on investigations into the origin of malaria. He will direct the work from Berlin.

Portuguese Medical Expedition.—A Commission had been appointed by the Portuguese Government to study the sleeping sickness in the Province of Angola. This Commission which will at the same time include amongst its scientific researches an inquiry into the etiology and the transmission of malaria will be composed of the following members: Drs. Annibal Bettencourt, Ayres Jose Kopke Correa Pinto, Jose Gomes Bezande, jun., Joao Braz Gouveia, and Annibal Celestino Correa Mendes.

Brains of 300 Suicides Examined.—Professor Meller of Kiel University, the renowned expert in mental diseases, as a result of autopsies made during five years on 300 suicides, states that he found that the brains of 43 per cent. showed distinct malformation; 29 per cent. of the remainder were suffering at the time of their death from acute febrile inflammation, and 142 of the whole number had organs diseased by alcoholism.

(From our Special Correspondent.)

German Surgical Society.—The 30th session of the German Surgical Society, which meets annually in its own building in Berlin, began on Wednesday morning, April 10th. The society has at present some 1050 members, an unusually large number of whom were present. The congress opened with the President's address by Czerny of Heidelberg. Czerny surveyed briefly ten lines of research work which are of especial interest, and promise to the surgeon; the etiology of the infectious and contagious diseases, especially tuberculosis and cancer, and the question of immunity. An important question is the treatment of hopeless cases of chronic disease. Russia has set the world a grand example by founding a hospital for hopeless cancer cases in connection with the clinic of Prof. Lewschin in Moscow. Czerny urges the teacher to provide his students with ample opportunity for practical work, and not to fear too much the danger of wound infection. He objects to the proposed admission of graduates of the "Real Gymnasien" to the medical course, as does the active German profession. The president closed his address with a brief mention of the members of the society who died during the past year, among them the French surgeon Ollier, of Lyons.

The first paper of the Congress was read by Kuester, of Marburg on "Renal Surgery in the 19th Century; a Review and a Glance into our Future." Kuester reviewed the history of renal surgery, a branch of surgery which has existed for but one generation. Its founder was the Heidelberg surgeon Simon; soon after the Anglo-Saxon surgeons took up the work, especially Morris; a little

later France followed, notably Le Dentu and Guyon. In 1868 an American performed a nephrectomy as a result of a false diagnosis, and a little later Spencer Wells did the same operation, yet Simon was the first to perform a well planned operation on the kidneys. From that time until 1875 only 8 nephrectomies were performed, in the following 5 years 48. The first statistics gave a mortality of 44.6%, a later one 25%; while the statistics of the last 10 years show a mortality of only 16%. One can rightly say that the operations on the kidney have lost their danger. The good results of the last 10 years are not to be ascribed exclusively to improved technique and wound treatment; a more finely developed diagnostic power and an increased knowledge of pathological anatomy have made better results. The beginning of disease can be more surely diagnosed. The main symptoms of the surgical diseases of the kidney are pain, tumor, and pathological urine. And yet we were unable to determine whether one or both kidneys were diseased until cystoscopy and catheterization of the ureters filled out these defects in our knowledge. Even then our diagnosis was not yet complete. The diagnosis of the kidney function has taught us that a kidney which excretes apparently healthy urine may still be diseased; for example, when two ureters are present, one of which leads into a healthy part, or when it is impossible to catheterize the ureter. We cannot always recognize the more delicate pathological changes in the kidney even after operative exposure of the organ. These defects in our knowledge are now filled by the diagnosis of the function of the kidney, and by the phloridzin test. The principal affections of the kidney requiring surgical intervention are: (1) Movable kidney. Kuester does not believe that the clothing of the modern woman explains the etiology of the disease, because floating kidney occurs very often in the women of Egypt, who wear loose clothing. Nephropexy is indicated and gives satisfactory results. (2) Wounds of the kidney requiring surgical aid to check hemorrhage. Simon recommended nephrotomy; the surgeon of to-day would limit nephrotomy to cases of extensive laceration, ordinarily, however, he would apply suture and tamponade. (3) Pyelonephrosis, primary pus formation, which Kuester would call cystonephrosis. Nephrotomy gives good results in tuberculosis of the kidney; in a ureter diseased in its entirety, and even a tuberculous bladder can heal after removal of a diseased kidney. The Roentgen rays have brought advances in the diagnosis of renal calculi. With a short exposure one can succeed in obtaining a picture of even the phosphate concretions. Nephrotomy or pyelotomy is indicated. Calculus of the ureter necessitates more extended operation, especially when their location is the neighborhood of the bladder. Kuester recommends in such cases osteoplastic resection of the sacrum according to the method of Morris, or laparotomy. In cases of cystonephrosis nephrotomy is indicated in order that one be able to save all healthy tissue. In cases of cystonephrosis or cyst kidney due to floating kidney, one often obtains good results by nephropexy with stretching of the ureter. (4) In the cases of tumor of the kidney, one often obtains good results by nephropexy with tumors are malignant, as for example the struma supranalis accessoria (Grawitz.) Partial nephrectomy is often indicated and has shown good results. In regard to the methods of operating, Kuester considers lumbar nephrectomy the only rational procedure, except in some cases of tumor where laparotomy is to be preferred, since complications can be recognized more easily and quickly.

The second paper by Casper, of Berlin, describes "Advances in Renal Surgery;" and the results of researches carried on with Richter. Many failures in renal surgery are due to faulty diagnosis; the question is not, is the organ to be left healthy, but is its function sufficient. The determination of nitrogen, of the freezing point, and of sugar, enable us to answer this question. The freezing point of the blood and of the urine is nearer that of distilled water, the nearer normal the kidney. The excretion of sugar is determined by inducing an experimental diabetes by injections of phloridzin. Casper has tested the method in 14 cases and demonstrates the results. Kuemmel, of Hamburg, "Practical Experience in the Diagnosis and Treatment of Diseases of the Kidney" has continued the experiments in the determination of the freezing point of blood and urine, reported by him at the congress of last year. He has tested the method in 100 cases and considers it one of the most valuable helps in diagnosis. The freezing

point of normal blood is 0.56; 0.55 or 0.57 he considers comparatively good, with 0.58 he would refrain from operating. His method is as follows: He first determines the freezing point of blood; if this is normal he examines the urine from each kidney; if only one kidney is diseased operation is indicated. Kuester considers the determination of freezing point, of urea and the phloridzin test absolutely necessary to diagnosis, without them fatal mistakes will be made. Kuester demonstrates the method for determining the freezing point of the blood. Braatz, of Koenigsberg, discusses in a short paper the changes in the kidney following median section of the organ. He believes that contraction of the organ follows even when the sutures are not drawn tight. Schoenberg, of Hamburg, "Demonstration of Roentgen Photographs of Renal calculi," explains the failure of the Roentgen rays in the diagnosis of gall stones and renal calculi by the fact that these concretions have too small an atomic weight, for this reason the phosphates ought really to be most easily photographed, but their specific weight is too small. The order is therefore as follows. Oxalates, phosphates and urates. It is entirely impossible to photograph the xanthin and cystin concretions. The difficulty in obtaining photographs of the calculi is, however, due in part to the diffusion of the rays in the body. Schoenberg describes his method of decreasing this diffusion by means of bad coverings for the tubes and by using suitable diaphragms and plates, and demonstrated skiagraphs of very small renal calculi. Steiner, of Berlin, describes a rare case of congenital malformation of the kidneys, the left kidney being absent, the organ of the right side being double. Symptoms were pain, tumor, urine containing pus. Steiner removed the upper kidney of the right side, and although pyonephrosis was present in the lower organ the patient recovered.

The paper by Goldmann, of Freiburg, discusses "The Treatment of Hypertrophy of the Prostate." Goldmann observed in a case where suprapubic puncture had been performed and the catheter had remained for eight days, that the patient had no further trouble with his hypertrophied prostate. Two years later he performed the autopsy on this patient and found that the bladder was fixed to the abdominal wall in such a way as to exert traction on the internal urinary meatus. He then experimented on the cadaver, and has operated on several patients. He recommends cystopexy, suturing the bladder to the abdominal wall in suitable cases of hypertrophied prostate. Loewenhardt, of Breslau, "On the Treatment of Tumors of the Bladder," makes a plea for the endovesical operation. He believes that the advantages of the septic alta, a better field of operation, thorough treatment of the tumor stump, are often more than compensated by the less severe endovesical operation, doing away with general anesthesia, and with less loss of blood. He considers the difficulty of manipulating the instruments of little moment. Colpocystotomy and Kelly's method are absolute. For tumors at the internal orifice he recommends Gruenfeld's method. Loewenhardt demonstrates an instrument for exact work with the cautery on tumors situated near the openings of the ureters.

The first paper on wound treatment was read by von Bruns, of Tuebingen, which will be published later in the Philadelphia Medical Journal.

Fraenkel, of Vienna, "Wound Treatment Following Operations for Localized Tuberculosis," believes that the small, and especially the very small tuberculous foci, cannot be reached by operation, and therefore recommends the treatment with iodoform and similar substances, the effect of which he explains by the inflammation and consequent formation of connective tissue, thus shutting off the pathological from the healthy tissue. In the discussion Kuster, of Marburg, recommends the treatment of infected wounds with the cautery with which he has obtained favorable results. He expresses his great mistrust of the use of carbolic acid. Koenig, of Berlin, believes that the best treatment of septic wounds is exposure and thorough incision. He uses zinc chloride in cases where Kuester recommends the cautery. We will obtain better results in the treatment of tuberculosis by thorough excision and formation of fresh wound surfaces.

The second session opened with an important paper by Kocher (Bern) "Report on the Second Thousand Cases of Extirpation of Goitre. (b) On an Operation for Struma intrathoracica. (c) On the Non-operative Treatment of Goitre." Kocher emphasizes first that he performs only excision, rarely enucleation. He has given up the latter

operation, and has not changed his technique. He never severs the muscles. He has constructed a forceps for compressing the isthmus not to exert pressure on the blood vessels, but to make the ligatures smaller. Kocher's mortality is 4%. Infection plays no role. He introduces no antiseptic into the wound, only the ligatures, for which he uses silk exclusively, are prepared with antiseptics. He has used the prophylactic treatment with thyroid extract before operation, in cases of diffuse and long standing goitre. He seldom or never uses narcosis, operating under cocaine, and so avoids the abundant hemorrhage caused by vomiting. Kocher would give struma intrathoracica an especial place in surgery. As a result of the struma profunda he has seen emphysema, bronchitis, tachycardia, etc., and he claims that goitre lung as well as goitre heart exists. The main question in cases of struma intrathoracica is whether it is movable or not, the movable struma naturally giving more favorable operative results. Kocher then demonstrated the diagnostic value of the Roentgen rays combined with percussion, and shows a goitre which extended to the second intercostal space. In regard to the technique of the operation for struma intrathoracica Kocher ligates all blood vessels and divides the isthmus before extracting the goitre; he demonstrates a forceps and a spoon which he has constructed as aids to rapid extraction. Tamponade is never performed, since it can cause choking, and is no guarantee that hemorrhage is checked. In regard to the medicinal treatment of goitre, Kocher states that he has given up the thyroid extract and has returned to the old treatment with potassium iodide. This treatment may cause acute and chronic iodism, which, however, can also be caused by thyroïdin. Kocher then describes interesting experiments which his son, Albert Kocher, has been making with iodum phosphate; he has found that the amount of iodine contained in the thyroid continually decreases in goitre, while the percentage of phosphorus increases; this is especially the case in pregnant women. After treatment with phosphorus, he observed in one case an increase of iodine from 0.018 to 0.4, in another case from 0.00862 to 1.2, while the percentage of phosphorus decreased. Kocher calls attention to the fact that in those countries where goitre abounds very little phosphorus containing foods are consumed, while in England, for example, where goitre is practically unknown, eggs and meat form the main food constituent. He thinks that this factor may be of influence upon the development of goitre. Kracke (Freiburg) discusses the treatment of goitre and reports on 420 operations performed at the clinic at Freiburg. One-third of these cases were in males, two-thirds in females. In 220 cases he has performed extirpation of one-half of the gland. Some of the first cases were total extirpations, the rest enucleations or resections. The modulated form was the most frequent, pure hypertrophy of the gland rare; 10 cases were of malignant struma, in one of which he successfully removed a metastasis from the struma; twice he removed accessory struma, once from the fossa supraclavicularis, once from the tongue. He operates, as does Kocher, under local anesthesia, avoiding narcosis on account of the bad effects of the consequent choking, vomiting and postoperative hemorrhage. He has had but two cases, one of them from heart trouble probably due to excessive use of thyroid extract, the other from tetany following extirpation of both lobes of the gland. He has seen dangerous postoperative hemorrhage only following enucleation, never since he has abandoned this operation and the narcosis. He could explain the rise of temperature following enucleations by the increased resorption of gland substance during the operation. Kraske points out that operations for goitre are becoming more frequent, and therefore that the treatment with thyroid extract can be of no value. He has abandoned it entirely. His opinion is that thyroid extract can have no effect on the pathological gland tissue, but the improvement in some cases to atrophy of normal tissue consequent upon non-use. The treatment is, therefore, theoretically wrong, and may even, by the production of connective tissue due to atrophy of the gland, make operation more difficult. He advises the profession to oppose the thyroid extract treatment. In the discussion, Goldmann (Freiburg) reports a case of tuberculous regeneration of a struma intrathoracica. Riedel (Jena) has operated in 500 cases. He calls attention to the fact that the goitre may develop on the left side with the thorax, and appear in the ordinary form on the right side. He thinks the instruments devised by Kocher unnecessary, provided

one makes a sufficiently long incision; he considers Kocher's incision too short and advises a curved incision extending from the jugulum to the ear. He operates as do Kocher and Kraske, without narcosis. Retere (Frankfort on the Main) reports a case so far advanced that he would not risk operation, but which was cured by treatment with iodids. Koenig (Berlin) calls attention to the goitres of the low lying level districts. He has seen 70-80 cases here in Berlin, at least half of which were in natives who acquired their goitre here. He asks Kocher how much of the gland should be left. Kocher answers that he finds $\frac{1}{4}$ of the gland a sufficient proportion to leave. Krause (Berlin) reports on "27 Intracranial Resections of the Trigeminal (among them 25 Extirpations of the Gasserian Ganglion) and their Results." The results following resection of the separate branches of the trigeminal are not sure; therefore, in cases of true trigeminal neuralgia, and where such a severe operation is indicated, the extirpation of the gasserian ganglion and the trunk of the trigeminal must be performed. Krause has performed resection of the branches in 2, extirpation of the ganglion in 25 cases in patients in from 30 to 72 years of age. He uses the temporal method of operation described by him in 1892. One patient, a woman of 58 years, in an extremely weakened condition, died in collapse; a man of 72 years died in consequence of sclerosis of the coronary arteries and heart failure; a third patient, a woman of 60 years, died three weeks after operation. The autopsy showed no inflammation, but an extensive edema of the meninges. Of his oldest cases there are still alive: A woman of 76 years and a man of 63, operated on, 8 and $8\frac{1}{2}$ years ago; a woman of 77 and one of 54, operated on $6\frac{1}{2}$ years ago; a woman of 43 and one of 51, operated on $5\frac{1}{2}$ and 5 years ago. None of these patients has had a return of their neuralgic pains. Krause finds it impossible to save the motor branch of the nerve. Among the post operative complications to be mentioned are, keratitis, especially in cases with an existing dacryocysto-blennorrhoea, or lagophthalmus following attempts at resection. Krause finds that these cases yield readily to suitable treatment: further, transitory paresis of the muscles of the eye, due to pressure upon the motor nerves during operation. Krause thinks that the results of this operation justify the risks of such a severe procedure. Heidenhain (Worms) presents two patients from whom he had successfully removed tumors of the brain, and reports two further operations. A man suffered from paralysis of the leg, Jacksonian epilepsy, later paranoia and choked disc. At operation the diagnosis of a tumor in the leg center was found correct, the tumor being a solitary tubercle about the size of a walnut. It is interesting to note that the paranoia disappeared after the operation. The patient still suffers from epileptic attacks and paresis of the leg. The second patient suffered since childhood from headache; later parasthenia and anesthesia appeared in the hand and arm. The diagnosis of cystic tumor in one arm center was found at the operation to be correct, the tumor being a cystic sarcoma of the size of a hen's egg. The headache and the choked disc disappeared immediately, and the patient has only slight sensory and motor disturbances in one arm. In the third case Heidenhain removed a melanotic carcinoma of the choroid plexus, and with the tumor the whole right temporal lobe. It is interesting to note in this case that the musical and the word sense supposed to be located in this region, were but slightly affected. In the fourth case with symptoms of tumor of the cerebellum, Heidenhain exposed the entire cerebellum, but failed to find the tumor; the autopsy showed a softened sarcoma of the cerebellum, situated exactly in the median line.

Barth (Danzig) "The Operative Treatment of Purulent Meningitis." Barth presented a boy who had received a knife wound in the region of the ninth dorsal vertebra. A week later the symptoms of meningitis appeared and lumbar puncture showed the presence of pus. Barth performed laminectomy and opened an extra-dural-abscess: fever continued high and he performed a second operation, this time opening the dorsal sac. Paralysis of both legs, the bladder and the rectum followed, but finally disappeared, so that the patient has recovered except for some slight sensory and motor disturbances and for a considerable gibbous condition which has developed at the site of operation in spite of a plaster cast.

THIRD SESSION.

The third session opened with a paper by Housell, of Tuebingen on "The Scientific Foundation of the Carbolic Acid Therapy of Septic Wounds." Housell has proven in his experiments that pure carbolic acid is entirely harmless when used in wounds or when injected into the tissues. The lethal dose by the mouth of the pure acid is 8 grs., of the dilute acid 2 to 3 grs. He has injected one-sixth gr. of carbolic acid into hydroceles with no unfavorable results, and places the maximal dose at 6 grs., for even the most extensive wound surfaces have in no case shown symptoms of poisoning. The time of application is one minute followed by a wash of absolute alcohol. Housell mentions this fact, long known, that absolute alcohol acts as an antidote to carbolic acid, probably by absorbing the acid more rapidly than does the fluid of the tissues. He believes that carbolic acid has a much more lasting antiseptic effect than sublimate. He emphasizes the value of thorough incision and would not recommend Phelps' method in any case of sepsis, yet he believes it to be a decided step in advance.

Haegler, of Basel, demonstrated microscopic sections of various kinds of ligatures which had caused pus formation.

Reinbach, of Breslau demonstrated drawings illustrating the histology of granulating wounds.

Blumberg, of Berlin, reported experiments on the value of the ethyldiamine of mercury as an antiseptic.

Kroenlein, of Zurich, "Contributions to the Surgery of the Brain," describes the case of a patient from whom he removed a tubercle of the brain: the patient has been in good health since the operation six years ago. In a second case Kroenlein diagnosed a tumor of the right gyrus centralis, but found no tumor at the operation one and one-half years later the patient died, and the autopsy showed a tumor at the site of operation. Kroenlein explains the case by assuming that the tumor was so small that he could not find it, but that grew later to the size of a hen's egg, as found at autopsy.

Merkens, of Berlin, described cases of "Encephalitis of the temporal lobe and other brain complications following Otitis."

Schjerning, of Berlin, gave a very complete paper, illustrated by numerous photographs and skiagraphs, on "The Shot Wounds Caused by Modern Firearms." He gave especial attention to the wounds caused by the field artillery projectiles. According to the author, it is impossible as yet to definitely answer the question whether one should operate immediately in cases of penetrating wounds of the abdomen. He considers operation indicated provided no further transport is necessary. He prophesies more serious wounds in the wars of the future, but believes that surgery is holding pace with the improvements in armament.

Kroenlein, of Zurich, showed true "copulated projectiles," bullets which had met at some period in their flight and had joined themselves firmly together.

Reger, of Danzig, discussed the experiments made by Kroenlein on the effects of bullets in the skull.

Ringel, of Hamburg, brings nothing new while relating his experiences with the Red Cross in South Africa.

Ziemssen, of Wiesbaden, advised the after-treatment of wounded soldiers and accident victims at the bathing resorts.

Bruns, of Tuebingen, read a paper on "Castration in Tuberculosis of the Testes." Bruns has collected 105 cases, 33 of which were castrations of both testes. In these cases he has observed that the epididymis is always first attacked, and that in almost all cases tuberculosis of the testes follows epididymectomy. The final results of operation were: 46% of cures following removal of one testis, cures lasting up to 34 years, 56% of cures following removal of both testes, lasting up to 30 years. No observer has reported psychological disturbances. Bruns arrives at the result that the statistics of castration is more favorable than that of conservative treatment.

Baumgarten, of Tuebingen, a guest of the society, reported the results of his experiments on tuberculosis of the testes. He concluded from his experiments on rabbits that the disease cannot advance against the excretory stream, i. e., that a tuberculosis of the prostate could never ascend the vas deferens to the testes; the bacilli are non-motile, and are further pure parasites, could not, therefore, advance by propagation in the secretion. In the same way he never observed tuberculosis of the kidneys

following tuberculosis of the urethra or of the bladder. He did succeed regularly, however, in obtaining tuberculosis of the vasa deferentia and of the prostate by causing tuberculosis of the testis.

Von Buengner, of Hannau, "On the Treatment of Tuberculosis of the Male Genital Organs," defends and strongly recommends his method, the so-called "high castration," carefully pulling on the vas deferens until it tears off. He succeeds in this way in removing four-fifths of the duct. He further describes experiments he has made in injecting the vas deferens with iodoform glycerine. By inserting the needle in the vas deferens he has succeeded, on the cadaver at least, in completely filling the canal. He recommends this method, believing that he has seen favorable results in the one method in which he has tried it.

Simon, of Heidelberg, reported on 107 cases of tuberculosis of the testis. Of these cases he has followed 92 and reports 66% cures. Of 29 removals of both testes 3 died, 21 remained cured up to 20 years. In one case he experienced psychical disturbances. He recommends castration.

Koenig, of Altona, on "The Technic of Castration for Tuberculosis of the Epididymis and of the Testes," recommends opening the entire inguinal canal. He operates after filling the bladder as in *Seccio alta* to avoid injuring the peritoneum. In the discussion Koenig, of Berlin, refused to give up his belief that tuberculosis can ascend along the vas deferens. According to his experience in the last ten years he has the impression that the vas deferens and the prostate are primarily diseased. He has tried injecting iodoform-glycerin into the epididymis, and has seen no results.

Gussenbauer, of Vienna, doubts the frequency of primary tuberculosis of some other organ; it can appear as primary tuberculosis of the testis or epididymis. In most cases it is continued with tuberculosis of some other organ; it can appear from the first to the seventieth year of age, in one or in both testes. Infection is brought by the blood current. He has seen cases with and without perforation, healed simply with a roborant diet. If operation be indicated we must operate as thoroughly as possible, but one must choose his cases.

Kramer (Caunstadt) believes the testis to be the seat of the primary affection, otherwise the diseased vas deferens and prostate would not heal after castration. He considers congenital impaction possible, thereby explaining the frequent cases of kidney and testis affection on the same side.

Henle (Breslau) reports that the clinic at Breslau has had negative results with the iodoform therapy.

Bier (Kiel) recommends hydrotherapeutic treatment with sea waters. He has seen one case of tuberculosis of the bladder and kidneys cured by sea waters(?)

Heidenhain (Worms) reports a case of "Resection of the Lung for purulent bronchiectasis and presented the patient."

A Case of Suprapubic Prostatectomy.—In the *Annales de la Polyclinique de Bordeaux* for April, 1901 Dr. E. Loumeau reports a case of suprapubic prostatectomy. A man of 72 had been forced to urinate two or three times nightly for some twenty years. After meals he had to evacuate his bladder at once. For two years he had noticed that effort was needed to begin urination. Suddenly hematuria appeared. He was pale, but suffered none. By rectal palpation the prostate was found as large as an orange. A catheter was left in place, yet the hematuria persisted. Hypogastric incision was made, and the median lobe of the prostate removed. The bladder was closed, drainage being left through the wound for a short time only. The hematuria disappeared. The bladder was washed out every few hours through the catheter left in place. Complete recovery followed in four weeks. The tumor of the prostate was a submucous adenofibroma. The diagnosis before operation rested between hypertrophy of the prostate with cystitis, and a tumor of the prostate. When complete extirpation of the prostate is not deemed necessary, partial operation, removal of the median lobe of the prostate by suprapubic incision will often be successful. [M. O.]

1.—Charles A. Morton reports a case of **ventrofixation of the sigmoid flexure for prolapse of the rectum**. The patient was a married woman, aged 24, who had suffered from prolapse for two years, which she was not able to control by means of a T bandage. The whole thickness of the rectal wall protruded for three inches. An incision was made one inch above Poupart's ligament and parallel to it. The sigmoid flexure was brought up and the meso-sigmoid sutured with silk at the upper angle of the wound to the peritoneum. The opening through the abdomen was made by splitting the various muscular layers so as to avoid a subsequent hernia. The patient made a good recovery from the operation, and about a year later showed a prolapse equal in size to a medium sized internal hemorrhoid. From a study of the cases reported, particularly those by Bryant, Morton is lead to think that the mortality of the operation is practically nil. He thinks it better to attach the meso-sigmoid to the peritoneum then to pass the sutures into the intestinal wall or to bring any portion of the bowel or its mesentery between the muscular layers of the incision. The next case reported is one of **excision of the cecum for carcinoma**, in which the growth was so movable as to closely resemble a floating kidney. Two years after the operation the patient is in good health and has no sign of recurrence. The next case reported is one of **obstruction from malignant growth of the colon**. In this case the growth was brought outside the abdomen and fixed by silk sutures. The following day the bowel above the growth was opened and the obstruction relieved. A fortnight later the growth itself was removed, and two months later the divided bowel was anastomosed. A few months after operation the disease returned at the seat of operation, and in the liver, requiring the making of an artificial anus, and subsequently the patient died of the disease. [J. H. G.]

2.—Bertram C. Stevens reports a case of **gall stones complicated by a cancer of the gall bladder, liver and pylorus**, and a fistula between the gall bladder and the pylorus, in which Mr. Mayo Robson performed the operation of removing nearly the entire gall bladder, together with a V-shaped portion of the liver and the pyloric end of the stomach. The patient made an uneventful recovery, and 8 months after the operation showed no evidence of the re-

turn of the disease. The growth was a columnar-celled carcinoma. [J. H. G.]

3.—J. M. Clarke and R. G. P. Lansdown report an interesting case of tumor of the brain, in which there was a marked absence of all localizing symptoms. The only two points which would suggest the side of the brain affected were increased dullness over the left parieto-occipital region and palsy of the left external rectus. Optic neuritis was also more marked on the left side. The general symptoms from which the patient suffered were those commonly seen in brain tumor. The patient was trephined over the dull area, and a distinctly encapsulated tumor, which measured $1\frac{1}{4} \times 1\frac{1}{4} \times \frac{1}{2}$ inches, was found and removed. The cavity filled immediately with what appeared to be normal brain tissue. No palsy followed the operation. After a few weeks all of the former symptoms returned, and therefore a second operation was deemed advisable. Upon lifting the scalp a large tumor was found protruding through the opening in the skull, and no healthy brain substance was visible. The tumor was dense and was easily separated from the surrounding brain substance, being removed in three or four portions in order to avoid making the bony orifice larger. The growth weighed $6\frac{1}{2}$ ounces, and was the size of a large orange. Examination of this growth and of the former one showed them both to be spindle-celled sarcomata. The patient was palsied after this operation, but gradually recovered from it. Eight months after the operation there was no sign of any recurrence of the growth, the patient had recovered his mental faculties, speech was normal, memory good, and there was entire absence of pain. The vision, however, improved very little, but there was no oculo-motor palsy. [J. H. G.]

4.—A. L. Whitehead reports a case of cavernous angioma of the orbit in a man aged 51 years, which had first been noticed about 10 years previously. The eye was pushed so far outward that the lids could not be completely closed, and ulceration of the cornea had set in. The movements of the eyeball were almost lost, and the pupil was dilated. The tumor was bluish-black in color, and could be seen above the globe. No pulsation was present, and there was no variation in size from pressure or other causes. The growth was not attached to the walls of the orbit. The fundus was healthy and the vision 6-60. The patient was etherized, the external canthus was divided, the capsule was dissected up, and the external rectus was divided, the tumor being then exposed and removed *en masse* with some difficulty, but without injury to the eyeball. The growth was lobulated and nearly encircled the optic nerve. Hemorrhage was slight, requiring no ligatures. The recovery was uneventful, and the vision improved to 6-9, with almost complete range of movement of the eyeball. The growth measured 5.4-5 cm. \times 3.7-10 cm. Examination of the growth showed it to be cavernous angioma of the fibrous variety. [J. H. G.]

5.—Buchanan reports the result of 300 cases of dysentery treated with salines during the year 1900, with only 3 deaths, making with cases already reported, a total of 855 cases with 9 deaths, or a mortality of only a little over 1 per cent. There were 51 relapses out of 300 cases; one case relapsed 4 times, 13 cases relapsed twice and 37 cases had only a single relapse. Of the 3 fatal cases, 2 were extremely acute cases in which meat-washing stools were constantly passed, and a condition of acute gangrenous inflammation of the colon rapidly supervened. The third fatal case, after the salines had failed, made a wonderful rally after a large dose of ipecacuanha (30 grs.), but died some 7 weeks later with symptoms of chronic diarrhea. At the necropsy the small intestine was found thin and atrophied, and the large intestine was a mass of chronic inflammation from the cecum to the rectum. The patient was a feeble, old and toothless man, aged 55 years. The author uses a mixture of sodium sulphate one drachm to one ounce fennel water, which is given 4, 6 or 8 times a day as the case requires. The saline is continued until every trace of blood and mucus disappears. In the majority of cases the

inflammatory products had disappeared completely in 2 or 3 days; in others they returned on the third or fourth day, necessitating a repetition of the saline. This method of treating dysentery is advocated for acute cases only; the author does not consider it a safe method for chronic or relapsing cases with ulceration of the colon. In cases of the chronic or relapsing variety he only uses the saline for one or 2 doses during an exacerbation of the chronic state, and then continues to treat the case with soda and bismuth or with salol, with an occasional dose of castor oil. For stools containing scybala nothing is so good as a dose of castor oil guarded by 10 minims of laudanum. Unless the physician can see the stools daily he can never use the method to its best advantage. He would hesitate to apply it in a routine fashion in out-patient practice, on account of the possibility of many patients having had previous attacks, and having their bowels in a state of unhealed ulceration. The success which has this year attended the treatment of chronic cases is believed to be due to careful dieting on rice water, and boiled milk and tyre, the use of anthelmintics and the careful occasional use of the saline, with Dover's powder and the intestinal antiseptics. Not a single case of liver abscess was found among the 885 cases here referred to. [J. M. S.]

6.—From the observations made on the larval stage of the anopheles and culex to withstand low temperatures it seems reasonable to infer that it is really the larvae that provide for the continuation of the species through winter in northern countries. [J. M. S.]

7.—Jones reports the case of a woman who was suffering from absolute paralysis of the extensors of the hands and feet. At first sight the case looked like one of lead poisoning. Domestic duties of a most exhausting nature reduced the patient's strength and debilitated her constitution, for which she had recourse to whiskey in moderate quantities. The condition was considered to be a typical case of alcoholic neuritis. After total abstinence from alcohol for 4 years, during which electricity from both the continuous and interrupted currents, was used regularly, the patient was cured. Seven years later she had a second attack of neuritis, following shock and the assumption of domestic duties for which she again had recourse to stimulants. After 2 years total abstinence and the renewed use of electricity she has once more regained perfect power over her limbs and her usual health. The author concludes that alcohol is responsible for much that has occurred in the recent outbreak of neuritis, and that in a great measure the arsenic has acted on systems saturated with alcohol. [J. M. S.]

8.—Benson reports the case of a woman, aged 45 years, who suffered from carcinoma of the breast. She experienced a sudden, very severe attack of pain in both arms, she had also cramp in the soles of the feet and pain in the shoulders. Later she felt a "shivering" sensation in both arms and up the back of the neck and head, accompanied by dull aching pain over the same area. There were also cramps in the calves of the legs which came on especially at night, and could only be relieved by getting out of bed and walking about. Whiskey eased her sufferings. She was totally blind in the left eye. When the patient seemed well on the road to recovery she had a smart relapse of pain and the respiratory muscles were mostly affected. The carcinoma of the right breast, which had become more fixed to the pectoral muscle, was operated on. During the night before the operation an abundant crop of herpes appeared on the sternum opposite the third rib, mainly over the musculospiral area of both arms above and below the elbows. This had quite cleared up when the breast was dressed a week later. The blindness and the painful symptoms were considered to be due to neuritis of the optic and the cervical nerves. [J. M. S.]

9.—F. B. Judge Baldwin reports a case of a boy aged 5 years, who gave the history of having swallowed a beech nut. Upon examination an hour after the accident, the boy had a husky voice and rather rapid respiration; examination with the laryngoscope showed normal position of the soft palate but no food in body could be seen. There were

impaired respiratory sounds on the left side in the neighborhood of the third rib. The respiration on the opposite side was undoubtedly exaggerated. Two days after the accident the patient had so much difficulty in respiration, that tracheotomy was thought advisable. This was done, and an examination of the respiratory tract and exploration with forceps revealed no foreign body. The patient made a satisfactory recovery, and nine days later two small pieces of the husk of the nut were found at the opening of trachea. [J. H. G.]

10.—Nicholson has found that in certain grave states of cardiac dilation, and in advanced valvular disease, the actual blood pressure as tested by Hill's instrument may be enormously high. This fact can only be accounted for by admitting that the ventricle is called upon to work at its highest pressure. [J. M. S.]

11.—E. Muirhead Little shows an illustration of an apparatus used for genu-valgum, where no operation is advisable. The apparatus keeps the knee perfectly stiff and consists of an external straight splint extending from the hip to the shoe, to which the knee is drawn by a series of straps. [J. H. G.]

12.—Eugene S. Yonge reports a case of polyp of the tonsil, which was pedunculated and easily removed with the guillotine. [J. H. G.]

1.—Christopher Addison begins his third and last lecture with the description of the peritoneal folds and pouches in the neighborhood of ileo-colic junction. Of the 40 cases examined 6 presented an ascending meso-colon, and 9 a descending meso-colon. The fact is emphasized that the sigmoid flexure of the colon has a very short mesenteric attachment. Seven cases showed the cecum wholly within the pelvis and 3 partly within the pelvis. It is thought that when the cecum is distended it is more likely to become enlarged into the pelvis rather than into the general abdominal cavity. In 22 cases there was a loop downwards of the transverse colon from the hepatic flexure. This loop is often firmly fixed and difficult to undo, being frequently adherent to the adjacent ascending colon. In 9 cases there was no such loop, but the transverse colon passed directly across the abdomen. There were six cases in which there was a prolapse of the transverse colon, this portion of bowel passing across the abdomen wholly below the umbilicus. The various positions of the liver, kidneys, pancreas, and spleen are next described. [J. H. G.]

2.—William Rose, in discussing the importance of early diagnosis and treatment of surgical diseases of the abdomen, speaks of those which arise from inflammation and those which may be classed as neoplasms. The diagnosis of perforating gastric ulcer is first taken up, and the great importance of early recognition of the condition urged upon the general practitioner. The importance of the early diagnosis of rupture of the intestine is next mentioned. Most stress is laid upon the fact that a diagnosis of perforation of the vermiform appendix is frequently made so late that operative interference is of little avail. Even in cases of localized abscess from appendicitis, the condition is too frequently submitted to the surgeon at a late day. The

prognosis of operations for cancer of the stomach and cancer of the pylorus is more influenced by an early diagnosis and prompt institution of surgical treatment than by any other factors. When a patient presents himself with a story of persistent vomiting which medicines do not relieve, together with fixed pain in the region of the stomach, and perhaps a feeling of resistance in the epigastrium, and still more if there be some history of preceding hematemesis, an exploratory laparotomy is indicated. The wonderful improvement in the mortality of pylorotomy is next mentioned. According to Barker's statistics, the mortality of this operation between the years 1882 and 1890 was 76.5 per cent., but between the years 1890 and 1898 the mortality was only 28.6 per cent., while in the hands of certain individual operators the mortality is much lower. The results of operations for intestinal cancer are not as satisfactory as in cancer of the stomach, the mortality here being about 35 per cent. Great stress is laid upon a careful investigation of both history and symptoms before arriving at a diagnosis, although this may be apparently easy in certain cases. Every avenue of information should be thoroughly investigated in every case. [J. H. G.]

3.—Bishop, in speaking of post-partum hemorrhage, remarks that in general there are two definite aims: 1. To obtain contraction of the uterus, and, second, to obtain local coagulation of the blood. He does not agree with most of the text-books, but believes that in many cases the uterus is utterly unable to contract, no matter what stimulus may be employed, and this inability increases with every ounce of blood which is lost. This inability to contract, he believes, is due to the physiological tire of the uterine muscle. In the treatment of such a condition, the uterus must be raised until it is higher than the heart, and that means that the foot of the bed must be lifted until it is much higher. The patient should be placed as quickly as possible in the Trendelenburg position, and the legs should be elevated and bandaged from below upwards. The venous loss is thus controlled, and it now becomes necessary to stop the arterial flow. This may be accomplished by direct pressure of the aorta, but as 5-6 of the blood supply to the uterus comes through the uterine arteries, pressure of these vessels will be preferable to compression of the aorta. This may be accomplished by placing the closed fist over its ulnar surface resting upon the aorta as it lies over the left side of the vertebral column and exerting sufficient pressure obliquely backwards and toward the right, so as to enable it to compress that vessel against the unyielding surface beneath. At the same time traction should be made upon the cervix firmly by means of a vulsellum forceps. This traction increases the angle in the uterine arteries, and thereby shuts off the flow of blood. The latter process Bishop considers most essential in the treatment of these grave cases of post-partum hemorrhage. [W. A. N. D.]

4.—Arthur Cooper, in speaking of enlargement of the inguinal glands, particularly as occurring in primary syphilis, calls attention to the fact that people vary in susceptibility, and that many persons who are apparently healthy have enlarged inguinal glands. He thinks that in most of these cases the condition is due to a mild form of balanoposthitis, which has not given the patient any discomfort. The diagnosis in a patient who had not noticed such enlargement of his glands might give rise to considerable trouble in the presence of a questionable sore. The glands which become enlarged from a chancre usually make their appearance in about ten days after the appearance of the sore, and the increase is gradual, as is also the decline of the condition. Not infrequently, however, the glandular enlargement is of an anomalous type, which may result in some confusion in making a diagnosis. The history of the previous condition of the groins is of the utmost importance in making a diagnosis, as well as the elimination of other causes. In fat people and those wearing trusses, Cooper has found inguinal adenitis frequently absent in primary syphilis. The application of irritants to the sore, he thinks, frequently results in suppuration of the glands. In

making an examination of the groins the patient should always be recumbent. [J. H. G.]

6.—Mott and Halliburton state that chlorine can be detected in the blood in various nervous diseases, such as combined sclerosis, disseminated sclerosis, alcoholic neuritis, and beri-beri. For the detection of chlorine, they either employ a chemical test or a physiological test. Chlorine has been found in the blood of animals in whom the sciatic nerve was irritated. Chlorine was always found in greatest amounts when nerve degeneration was at its height. [F. J. K.]

1.—Ingals emphasises the usefulness of adrenalin and adrenalin chloride, the active principle of the suprarenal gland in the treatment of some of the acute, sub-acute and chronic diseases of the nose and throat. He employs adrenalin and adrenalin chloride in solutions, the strength of which varies from 1 to 1000 to 10,000. [F. J. K.]

2.—C. H. Mayo speaks of the great frequency of hypospadias occurring, according to Rennes, Kaufman and others, once in every 350 males. The various operations for the relief of this condition are classified and described: many of the operations are illustrated. The operation which the author recommends is one in which the deficiency of the urethra is supplied by making a urethra from the skin of the prepuce and dorsum, which is carried over the front of the glans and attached to the distal portion of the urethra. A silk-worm-gut drain is used through the urethra and the bladder drained by a catheter through the perineum. The author reports 4 cases the last two of which were operated upon after this manner with good results. [J. H. G.]

3.—Kober writes that pollution of streams used for public water supplies, by individuals or communities, should be regarded as a grave offence. In order to prevent river contamination sewerage should be disposed of properly. Irrigation of the waste products on the so-called sewerage farms offers the most approved measure in preventing pollution of streams. In addition to this measure, water should be filtered in order to prevent the spread of the so-called water-borne diseases. The idea that rivers purify themselves, the author states, is erroneous, and that biologists have almost concluded that "no river is long enough to purify itself." [F. J. K.]

4.—After briefly reviewing the literature on the subject of floating kidney in children, Abt states that from an etiological standpoint congenital origin and congenital predisposition must be regarded as the most important factors. Acute and chronic trauma may be exciting causes. The symptoms of floating kidney are most often latent. In some cases there may be moderate pain, while in others the pain may be paroxysmal and colicky in character and accompanied by chill, fever, sweating, and vomiting. The attacks of acute pain are due probably to twisting of the kidney pedicle. The kidney is often tender upon palpation and the urinary secretions may be reduced; in some in-

stances hydro-nephrosis may develop. Gastro-intestinal symptoms are common. The author gives the report of five cases occurring in children, three in girls and two in boys. In four cases the right kidney was displaced. [F. J. K.]

5.—Halberstadt gives an interesting resume of the progress that has been made in obstetrics during the last half century. He remarks that beyond the introduction of asepsis, the use of anesthesia, and symphysiotomy in parturition there has been but little else that is new in obstetrics. On the other hand gynecology has claimed all the honor in the progress in this branch of medicine. Halberstadt in speaking of the use of anesthetics remarks that the parturient state is the only condition of the system in which anesthetics judiciously administered are entirely devoid of danger. In puerperal eclampsia chloroform is especially indicated because of its direct, rapid, and general action controlling nervous physiological irregularities, exciting secretion, relaxing the os and perineum, and, in short, preparing the parts so as to aid the accoucheur in his manipulations. Its application is universal; no disease of the heart or lungs should forbid its use. Owing to the fact that uterine contractions are sometimes lessened by the administration it may be regarded as important to precede it by an oxytocic in all labors and at any stage when the pains are slight, so as to increase their force, and also to guard against postpartum hemorrhage. In no instance has been seen narcosis of the child attributable to the anesthesia. [W. A. N. D.]

6.—Reed sums up his conclusions in regard to some of the principles relating to diatetics as follows: Not until we have cured our patient of their diseased digestive organ should we advise them to "eat everything." In addition to partaking of the proper articles of food—those that will nourish and strengthen in desired amounts,—the patient should take regular daily exercise. Even persons in good health should not be advised to "eat everything," for idiosyncrasies must always be carefully considered. [F. J. K.]

7.—Crothers concludes that alcohol, taken in any form as a beverage, is a poison or produces other poisons. It acts as an anesthetic and not as a so-called stimulant or tonic. It decreases elimination and increases waste products of the body. The clear indication of the auto-intoxication of alcohol is seen when functional and organic symptoms disappear by abstinence in those individuals who are accustomed to spirits. [F. J. K.]

8.—Stewart advocates the establishment of a national bureau of materia medica, the chief objects of which are: (1) To establish standards of materia medica preparations; (2) The bureau should act as a medium of communication between manufacturers and those engaged in marketing products and those engaged in scientific work in laboratories and hospitals; (3) To gather knowledge of materia medica products, establish a system of laws pertaining to this subject, and to publish for the benefit of science; (4) Those manufacturers who conform to the required standards should be aided by the bureau. [F. J. K.]

9.—Estes makes a plea for the establishment of hospital cars for railway service. He mentions the advantages that would be derived, not only to the patient, but to communities. Individuals suffering from infectious diseases not infrequently travel from place to place and spread disease. Careful disinfection could be practised with Hospital Cars and therefore reduce the risk of communicating diseases. [F. J. K.]

- 7.—The Relation of Arterial Changes to the Heart. BEVERLY ROBINSON.

1.—Beck reports that the essential nature of this disease was a much degenerated (cheesy) tissue in the state of necrobiosis, which seemed to have a sort of magnetic effect on the dissolved calcareous salts, inducing them to amalgamate. Such petrifications are found in tuberculous (cheesy) foci of the lungs, and not infrequently in endocarditis and pericarditis, in old pleuritic bands, in uterine myomata, and in renal epithelium. In the walls of blood-vessels, as well as in degenerated thyroid glands, he states that he has had an opportunity to define the mode of petrification by means of the Roentgen rays. The tendons and their sheaths seem to be but seldom the seat of predilection for calcareous deposits. Still, with the increasing popularity of the Roentgen rays, more light may also be thrown upon the pathology and significance of this hitherto unknown disease. [T. M. T.]

2.—Booth recommends, instead of a general anesthetic, the combined use of cocaine and adrenal capsule in correcting deviation of the septum, for the following reasons:—(1) There is less immediate danger from heart failure or suspension of breathing, accidents not uncommon in chloroform and ether anesthesia; (2) The hemorrhage during the operation is nil, and he believes that the danger of secondary hemorrhage following the use of adrenal is offset by the danger of the suspension of animation following the use of a general anesthetic; (3) The operator can see what he is doing at every step during the operation; (4) The patient can sit upright and hold his head in place during the operation—an obvious advantage; (5) No special instruments are necessary; (6) The operation can be done as well in an office as in a hospital; (7) The pain is insignificant, and certainly less distressing than the nausea and vomiting following the use of ether. [T. M. T.]

6.—Brickner emphasizes the following important duties of the anesthetist for the prevention of anesthesia-paralysis:—(1) The arms should never be allowed to hang over the edge of the table. The position threatens the musculo-spiral nerves by pressure, and the entire plexus by stretching; (2) Rotation and superextension of the head should be exercised only while emergency required it; (3) Prolonged pressure of any kind should be avoided, be it that of an assistant's hand or body, or that of a harness; (4) The common practice of drawing the arms alongside the head, however much it may contribute to the convenience of the anesthetist and the comfort of the operator should not be tolerated. Avoid allowing either to remain for more than a few minutes in any one position, however innocent that position may appear to be [T. M. T.]

MEDICAL RECORD.

6. Albuminuric Retinitis in Pregnancy; Premature Labor; Death in Utero of Twin Child; Puerperal Convulsions; Hemiplegia; Acute Mania: Death. JOSEPH N. STUDY.

1.—John Rogers, Jr., reports a series of 7 cases in which four laryngotomies and ten tracheotomies were performed without a death which could be ascribed to the operation. Great difficulty was found in administering an anesthetic. Cocaine was employed in his third case, and was a great

improvement. The author recommends that it be used when the patient is controllable, but in children, or nervous patients, chloroform is required. Laryngotomy, except for tumor, is absolutely useless. The high opening of the respiratory passages, however, has some distinct elements of safety in its favor. A low tracheotomy presents some of the doubtful advantages of a less probability of subsequent stricture above a long retained canula. On the other hand, there is serious risk of wounding some of the large veins at the upper border of the sternum. In general, and especially for emergencies, and for chronic stenosis, which must subsequently be treated by intubation, the high operation is safer and better than the low. The author has met with no difficulty on account of granulations, which are often heard of as serious dangers in cases of a long retained canula. It is not always possible to diagnose at once the locality of the obstruction, but if a short canule does not relieve the dyspnea, a long one should be used, and a stomach tube is a good substitute. [T. L. C.]

2.—Lewis Fischer reports a case of recurrent vomiting of nervous origin. The child came under observation when 8 years of age. There was no family history of any chronic nervous disease, or "neurotic" element. The child had suffered from a violent pertussis which lasted 9 months. After the cough subsided the vomiting remained, even to the present time (and she is now 14). She is a frequent sufferer from tonsillitis. She continually complains of pain in the stomach, which is not distinctly localized. The symptoms somewhat suggested ulcer. As to the frequency of vomiting, sometimes the child vomits a dozen times a day. Occasionally but once, and rarely a day passes with no vomiting at all. The urine shows the presence of acetone and indican. The former indicates a disturbance of metabolism, but it is well known that acetonuria does not of itself cause vomiting. The condition persists despite treatment. On several occasions a distinct hyperchlorhydria was determined; again the gastric juice was normal. [T. L. C.]

3.—Heinrich Stern has observed that the habitual, or excessive, use of tobacco may not only exaggerate an existing glycosuria, but it may be the causative factor of the glycosuric condition. He has found that tobacco may influence the pre-established pathological output of urinary glucose in the following ways: First, by protracting the duration of transitory glycosuria, and by imparting to alimentary melituria a certain degree of chronicity. 2. By increasing the quantity of dextrose in the 24 hours' urine in the transitory as well as the chronic forms of glycosuria. 3. By transforming the lighter degrees of chronic glycosuria into the graver forms. Four cases are cited to illustrate these points. The following experiment has been frequently made by the writer: He orders a patient with a tendency to alimentary glycosuria to ingest 150 gram. of dextrose (after the complete evacuation of the bladder). The dextrose is usually given after his mid-day meal, and the patient is ordered to abstain from any work for the rest of the day. The urine for the following 6, 8 or more hours is collected separately and examined for glucose. The latter probably appears in the urinary secretion until the sixth, or, more rarely, the eighth hour after its ingestion. The same experiment is repeated the next day, but the patient is ordered to smoke at least 3 or 4 strong cigars in the afternoon. On this day it will be found that the glycosuria frequently persists for 8, 10 or even more hours. [T. L. C.]

4.—William S. Gottheil some time ago reported a case of pityriasis versicolor occurring in the palm. This was unique, since authorities were agreed that it never appeared in that locality. It is almost the same with the face. The parasitic growth occasionally extends from the chest to the neck, and even to the jaw. He has recently met with a case of primary infection of the face, and of the face alone. He has been able to find no record of a similar primary involvement. [T. L. C.]

5.—Floyd and Gier report an extreme case of simple

anemia in a young mulatto of 19 years. It followed pregnancy. On admission, examination of the blood showed 12% of hemoglobin, 750,000 blood cells and 33,000 white cells. The blood was examined once a week during the patient's stay in the hospital, 2 months, and every two weeks, then after a month or two after her discharge. The hemoglobin was moderately unevenly distributed. "Ringing" and extreme pallor of the cells was not present, except in the small deformed cells. A few nucleated reds were found. There was an abnormally large percentage (over 30) of small mononuclear leukocytes. There was no excess of eosinophiles and no myelocytes were found. A progressive improvement followed under appropriate treatment, and at the eighth month the blood count showed hemoglobin, 80%, and 4,800,000 red blood cells. A number of progressive counts are included in the article, and the case is classed as one of simple anemia because of the rapidity and degree of the recovery. Analysis of the urine and feces were made daily during the first four weeks, and the case was subjected to a thorough clinical study. [T. L. C.]

6.—J.N. Study reports a case of **albuminuric retinitis** in pregnancy. At the third month of pregnancy 5% of albumin was found in the urine, which increased to 10% at the fourth month, when the patient was passing 400 grains of urea in 24 hours. She suffered from constant pain behind the eyes, and the vision was reduced to 40/80. Her condition did not improve at any time, and the symptoms gradually grew worse. Premature labor came on without warning at the eighth month. Within ten minutes a premature male child was born weighing four pounds, which now, at six months, is developing into a strong child. Within fifteen minutes of the birth of the first child a second undeveloped male child was born dead. It had probably been dead for two months. A temporary improvement followed labor, but very soon symptoms of **partial hemiplegia** appeared, and the patient, after remaining in a **maniacal state** for some four weeks, died about three months after the birth of the child. [T. L. C.]

MEDICAL NEWS.

April 27, 1901. (Vol. LXXVIII, No. 17).

1. The Study of Internal Medicine. WILLIAM OSLER.
2. The Relation of the Student of Medicine and the Recent Graduate to the Field of Surgery. GEORGE RYERSON FOWLER.
3. The Medical Man in the Navy. W. K. VAN REYPEN.
4. The Municipal Health Department System, and More Especially in Reference to Its Advantages and Disadvantages as an Opening for the Young Medical Graduate. ARTHUR H. GUERARD.
5. The Advantages of Examining for Life Insurance. BRANDRETH SYMONDS.
6. The Outlook for the Young Physician in State Hospital and Sanitarium Work. CARLOS F. MAC DONALD.
7. The Medical Man in the United States Marine-Hospital Service.

3.—Van Reypen, in his article on the **medical man in the navy**, gives the following order of examinations:—1st. Physical; 2d. Written; 3d. Oral; 4th. Clinical; 5th. Practical. 1. The physical examination is necessarily thorough, as the question involved is not simply one relating to probable length of life, but more especially to continued physical ability to perform duty, for the officer is paid when sick and, when permanently incapacitated for active naval service on account of physical disability, has the privileges of the Retired List, where, if his disability has been an incident of service, or his retirement is on account of age, he receives as much as seventy-five per cent. of the pay at sea. 2. In the written examination the candidate is required to address a letter to the Board of Examiners, stating the date and place of his birth, the school or college at which he received his general education, the medical school

or schools in which he received instruction, and if he is an alumnus, the date of his graduation, the time when he commenced the study of Medicine, also the titles of text-books studied; the opportunities he has had in engaging in the practice of his profession and whether he has or has not been a resident physician or interne in a hospital. His name in full and post-office address should be appended. He next prepares a thesis upon some professional subject indicated by the Board, and then makes written answers to questions on the usual professional subjects, including hygiene and quarantine. 3. The oral examination is upon general educational subjects and the usual professional branches, including hygiene and microscopy. 4. The clinical examination of the patients is made at a naval hospital, and includes the use of microscope, thermometer, laryngoscope and ophthalmoscope. 5. The practical examination comprises surgical operations on the cadaver, the application of splints, bandages and surgical dressings, the use of the microscope and chemical and pharmaceutical manipulations. He must have a good general education, but need not necessarily be a college graduate. [T. M. T.]

4.—Guerard gives the following duties of the **sanitary authorities** in connection with health department work: They must insure to the community and to each individual an abundant supply of pure air, light and water, and wholesome food. The preservation of the purity of the air and the furnishing of an abundance of light and ventilation, involves comprehensive measures relating to the character of the habitations, their construction, their cleanliness and the cleanliness of their surroundings; the provision of efficient plumbing; good sewerage; sufficient air-space, and the prevention of overcrowding; protection against noxious vapors or odors arising from offensive trades, slaughter-house, gas-works, decomposing animal and vegetable matter, and the purity of the atmosphere from suspended solid particles. It is also incumbent upon the sanitary authorities to prevent adulteration and to guarantee the wholesomeness of food—meat, milk, fish, fruit and general articles of consumption. The purity and quality of various drinks must be inquired into, and the relative food values of different products determined. Besides special inspection relating to plumbing, ventilation, overcrowding, inspections of food, etc., there are also general inspections relating to street excavations, wells, privies, stables, the conditions surrounding the removal of garbage and dead animals, the conditions of public places and places of assembly, the manner and place of burial, etc. Another special feature of the work relates to the restriction and prevention of infectious diseases, the inspection of reported cases, and the quarantine of patients affected with contagious affections and their removal to hospital when required; the disinfection of infected premises, clothing, etc. [T. M. T.]

7.—General information regarding the **medical man in the United States Marine-Hospital Service** may be summed up as follows: Examinations are usually held once a year, in the spring, sometimes more frequently. The boards meet either in Washington or in New York. All applicants must be graduates of reputable medical colleges. They are given, first, a physical examination, including a test of color vision. Absolute health is a prerequisite to appointment. Each applicant then writes a personal history of himself, giving his educational advantages, etc. A written examination is then conducted in the chief branches of medicine, including anatomy, physiology, chemistry, materia medica and therapeutics, practice of medicine, practice of surgery, obstetrics and diseases of women, hygiene, pathology and bacteriology. This is followed by a brief clinical examination in a hospital. Added to this is an oral examination in common school branches, also the collateral sciences and literature, sufficient to demonstrate the scope of each applicant's preliminary education. Each applicant reaching the grade of 80 is eligible for one year and appointments are made to vacancies as they occur in the relative order of merit. [T. M. T.]

BOSTON MEDICAL AND SURGICAL JOURNAL.

April 25, 1901. (Vol. CXLIV, No. 17.)

1. Remarks on Anesthesia—General, Local and Spinal. MAURICE H. RICHARDSON.
2. Experience in Search of a Cure for Asthma in the Far Southwest, with Observations on the Comparative Value of Different Sections in Respiratory Diseases. ROBERT BELL.
3. Cholera During Pregnancy. F. S. NEWELL.
4. The Economics of the X-Light Tube.—An X-Light Plate-holder.—Removing the Irritating Gases Produced by X-Light Generators. WILLIAM ROLLINS.

1.—Richardson believes that the dangers of etherization are trivial and that the subcutaneous use of cocaine, especially in extensive dissections will be found to be much more hazardous. The only justification for the use of extensive local and of spinal anesthesia lies in diminished risk to the patient. One of the dangers from general anesthesia is that real one of regurgitation into the throat from a distended stomach or intestine when the patient is unable to swallow. Another danger arises when the patient has extensive disease of the heart, lungs or kidneys. In such cases, it may be advisable to substitute local or spinal anesthesia for general anesthesia by ether. Local anesthesia is to be preferred for all trivial operations in regions where it can be thoroughly applied, but for operations like appendectomy, the radical cure of hernia, excision of the elbows and amputations of arm or leg, seem to the author to be very far from advantageous as compared with ether.

In some very feeble patients the effect of ether is beneficial; but the dangers, definite though they may be, are unlikely to be lessened by methods whose dangers are as yet unknown. In acute febrile diseases, it seems a question whether the dangers of general anesthesia will be avoided by local or by spinal cocaineization. The use of these doubtful methods in operations of emergency seems ultraradical, if not, with our present knowledge, unjustifiable. Another class of diseases inviting disaster under general anesthesia comprise operations upon deep cervical phlegmons, tumors close to and adherent to the trachea, inflammations and growths involving or pressing upon the recurrent laryngeal nerves and imperative operations upon the trachea and larynx. In these cases the value of local anesthesia is great, and it is the author's custom to use cocaine when possible. When ether is carefully given there is no distressing anxiety as to the outcome, and the author feels confident of the patient's safety and has that confidence shaken only when the anesthetic is in the hands of the careless and overconfident or when the patient's condition is desperate. He cannot believe that either spinal or local cocaineization, after 50 years of use as extensive and varied as that of ether, or even of chloroform has been, will show a safety to be compared with them. [J. M. S.]

2.—Arizona, in Bell's judgment, stands first as a climate of value for all respiratory diseases. He places Tucson at the head of the list of cities in Arizona to which to send such patients. Tucson has an elevation of about 4,000 feet; there is very little irrigation carried on near it; its annual rain-fall is from 8 to 10 inches; its mean average annual humidity is 36%. It is singularly free from wind, dust and sudden changes of temperature because it is nearly surrounded by high mountains. It has a maximum of sunshine and is a desirable place to live in. South California is frequently resorted to by tuberculous patients, but in the author's opinion there are many places that are much better for this class of invalids. Although the annual rain-fall is but 15 inches the dense fogs which prevail all over Southern California, except in the mountains, render the climate too moist for many tuberculous patients and for others suffering from such respiratory diseases as asthma and chronic bronchitis.

Physicians in sending patients to the far South-west should be careful to send them in the first stage of their disease. Second and third stage patients may have lite prolonged but rarely recover. On arriving at his destination the patient should spend the early months of his sojourn in resting and living as much as possible in the open air. Nervous patients and patients who are liable to hemorrhage should be sent to a moderate altitude. Pa-

tients who are too weak to endure the fatigue of a journey and those who are likely to become a tax on the people of the West should remain at home. Every patient should distinctly understand that he is to remain in the West after his cough has ceased until he has regained and held his weight, and under no consideration should he return East until he has received the sanction of a competent and experienced physician. [J. M. S.]

3.—Symptomatically the chorea that occurs in pregnant women is identical with infantile chorea. The special conditions under which it develops and the grave form it tends to assume in the large proportion of cases give it a special significance, so that it deserves to be considered by itself as a definite complication of pregnancy, rather than as a modification of the more common chorea of adolescence. An important factor in the etiology of this affection is the existence of a previous chorea during childhood. Heredity and nervous impressionability are also important etiological factors. Previous infectious diseases, probably, also have an etiological importance in relation with the disease, in that they prepare the ground for its development. Pregnancy alone is no more to be considered the direct cause of chorea than is active growth in children the cause of infantile chorea. The movements come on gradually in the majority of cases and become more violent as the time of delivery approaches. In mild cases, the fetus may live and be born at term; in severe cases it usually dies and causes abortion or premature labor. The chorea usually lasts the whole time of gestation and sometimes days or weeks after delivery. As a general rule the spasms become less violent after delivery, a fact which indicates the appropriate treatment in severe cases. The mortality in the published tables varies from one in every 17 to one in 3½ cases. Newell considers rest in bed and freedom from worry valuable adjuncts to the treatment by sedative drugs. The history of an illustrative cases is given. [J. M. S.]

4.—Rollins believes that the most important discovery to be made in X-light tubes is to find how to keep the character of the light constant. Meanwhile, the best way to excite an X-light tube is to use surges of millions of volts and many horse-power, each surge lasting for not more than a millionth of a second. No X-light should reach a plate except after it has passed through the patient being photographed. The author states several requisites for a satisfactory plate-holder for X-light photographs. Since a powerful X-light generator produces ozone and combinations of nitrogen and oxygen which are irritating to the respiratory mucous membranes, a fan should be placed within the case of a static machine to drive the gases into the nearest chimney. [J. M. S.]

AMERICAN MEDICINE.

6. Gastroptosis. ALEXANDER McPHERDAN.
7. Pneumonia. A Historical Review of its Treatment. WM. CRAWFORD JOHNSON.

2.—William Henry Porter concludes his paper on the good and bad effects obtainable of digitalis used as a therapeutic agent, with the following summary: The composition of digitalis is chemically speaking, very complex, and some of its active principles antagonize others. The different preparations differ widely in their composition and action. Its cumulative action is due to it contracting the arterioles thus shutting off nutrition. It is a useful but dangerous remedy and has but a limited range of use in lesions of the mitral valve and even then only for a short

time. It should only be employed when there is low arterial tension and marked venous engorgements, and as soon as these conditions are overcome its action should be suspended. As a diuretic it is only useful when there is low arterial tension, venous engorgement, and obstruction to the exit of blood from the kidney. Acting upon the normal, and in all diseased conditions, in which there is obstruction to blood from the exit of the kidney, it decreases the excretory activity of the renal glands and impairs a nutritive activity. Finally, if pushed to the fullest extent it may completely arrest the functional activity of the renal glands. [T. L. C.]

3.—Hemmeter concludes his article (partially abstracted in our last issue), upon the logic of hydrochloric acid therapy by recommending HCl for its efficacy in supplementing the digestive work of the stomach in bringing about the normal condition for duodenal digestion. He prescribes 20 drops of diluted HCl in 2 ounces of water every 15 or 20 minutes, beginning 15 minutes before the meal; then 20 drops are taken during the eating, and 20 drops half an hour after the meal. He recommends that the medicine should be taken through a glass tube and the mouth rinsed afterwards with a weak solution of sodium carbonate. [T. L. C.]

4.—Howard Lilienthal reports an extremely bad case of hyperplastic colitis accompanied by papillomatous growths throughout the entire colon and a small portion of the ileum, which was not improved by any form of medical treatment. In order to give the lower bowel a rest a left inguinal colostomy was done with marked relief of symptoms, the hemorrhages entirely ceasing. The patient improved so much after this operation that the artificial anus was closed. The symptoms all returned, however, and the patient came under Dr. Lilienthal's care very anemic and weak and having about 12 stools a day. On December 30, 1899 he established an artificial anus in the right inguinal region in order to give the entire colon a rest. At this time he used irrigations of silver solution, etc., without apparently improving the condition of the mucous membrane. The patient's general condition, however, greatly improved and the hemorrhages again nearly entirely ceased. On March 6th an end-to-end ileo-sigmoidostomy was performed the colic end of the ileum and the proximal end of the sigmoid being invaginated. A Murphy button was used in making the anastomosis, and was passed 13 days after the operation. The general condition of the patient improved but the stools were very frequent; these, however, were reduced to about 9 a day in a few weeks. Irrigation through the colostomy wound made appearance in the rectum which could only be explained by a fistulous opening at the divided portion of the sigmoid which was confined by subsequent operation. The patient was greatly inconvenienced by the fistula of the colon and insisted that something be done to relieve it. On June 15, 1900, the entire colon was removed beginning at the rectum. The patient developed pneumonia after this operation but recovered from it. On the fourth day there was a fecal discharge from the right iliac wound which could be explained. On June 27th an abscess ruptured at the site of the old left colostomy and there was discharged a portion of gangrenous meso-colon. On October 6th the right wound was explored to ascertain the cause of the fecal discharge and here was found a "single piece of intestine, not a loop, passing directly into the fistula." This was invaginated and the wound closed. The patient made a good recovery from this last operation and finally all of the wounds closed and the patient was exhibited on January 14, 1901 in excellent general health and was having only 2 stools a day. [J. H. G.]

5.—Garrison has made a study of intestinal antiseptics in its relation to the puerperium, with special reference to the use of simple aseptic pads in obstetric practice. When called to a case of obstetrics she sees that the intestinal tract is rendered aseptic as soon as possible. If this is not possible before delivery she begins to cleanse the bowels as soon as possible after. For this purpose the saline laxatives are preferable on account of their antiseptic action, and the best of these is the tartrate of potassium and sodium. She begins with dram doses within four hours of delivery and gives a dose every four hours. The laxative may be aided by enemata if the bowels do not act in twenty-four hours. If the bowels have moved during labor, she allows twelve hours to elapse before giving a saline, and if the bowels have not been acted upon freely or the tongue

is foul she gives a compound cathartic pill within twenty-four hours of the delivery. In addition to these precautions the gastro-intestinal tract is further rendered free from danger by giving other antiseptics as salol and quinine. A flow of pure blood is Nature's way of freeing the parturient canal of toxins. This is favored by means of a binder which holds the uterus up in the proper position and prevents obstruction at the cervix. Aseptic pads should then be applied to prevent the entrance of the germs of putrefaction. [W. A. N. D.]

6.—Alexander McPhedran reports 3 cases of gastropnoptosis. He offers the following conclusions: Gastropnoptosis frequently exists without symptoms as long as the functions of the stomach are performed efficiently. The symptoms of the condition arise from the retention and decomposition of food in the stomach with the local irritation and constitutional poisoning resulting therefrom. In the condition known as Glenard's disease the gastropnoptosis, or splanchnoptosis, plays often a minor part in the production of the symptoms. In not a few instances the splanchnoptosis is rather the result than the cause of the condition. [T. L. C.]

UNIV. OF PENNA. MEDICAL BULLETIN.

April, 1901.

1. A Series of Twelve Articles on Medical Men Prominent in the Civil and Military Affairs of Revolutionary Times. FRANCES R. PACKARD.
2. Notes on Fifty Operations for Otitic Extra-dural Abscess. B. ALEX. RANDALL.
3. Primary Sarcoma of the Spine. JAMES K. YOUNG.
4. A Critique of Certain Methods of Gastric Analysis. DAVID L. EDSALL.
5. Adrenalin, the Active Principle of Adrenal Extract, a Proposed Agent in Morphin and Opium Poisoning, etc. EDWARD T. REICHERT.

1.—Dr. Francis R. Packard continues his interesting series of articles on medical men prominent in civil and military affairs of the Revolutionary Times. In this paper he presents sketches of Dr. John Brooks and Dr. William Eustis, both Governors of Massachusetts, and both physicians of prominence, and Dr. Nathaniel Freeman, soldier and Judge. [T. L. C.]

2.—B. Alexander Randall contributes a paper in the nature of a critique on 50 operations for otitic extradural abscess. Post-mortem teachings have more and more emphasized the frequency of the aural causation of extradural abscess. Very frequently extradural collections of pus present only aural symptoms. The efficacy of the Wilde incision formerly practiced, a mere periosteal section over the inflamed mastoid is no longer believed in. External mastoid periostitis may primarily occur, but the belief is gaining that the reported cases have been largely errors of diagnosis. Randall believes that those cases which have apparently been much benefited by heat or cold to the aural region, hot douching in the canal, leeching or antiphlogistic measures, would have done equally well without such treatment. When pus is present on, or in the mastoid, delay is of very great danger. Pus upon the surface of the mastoid is rarely formed there. It may have burrowed out sub-periosteally along the canal or may have oozed through the apparently healthy cortex. Its exit through a large bone sinus may be so frank as to tempt us to believe that drainage is already adequate without operative attack on the bone. Experience shows this is fallacious. The healthiest looking bone may wall in a pus-collection which is not merely menacing local structures, and tending to general pyemic infection, but is burrowing between the dura and the skull and locally infecting the intracranial contents. In 50 cases of extradural abscess operated upon by the author he has been struck by the usual absence of symptoms suggesting intracranial mischief in even the worst cases. The subnormal temperature or slowed pulse was lacking wholly, although the bulk of the intracranial collection was often enough to pre-suppose decided pressure. The extent of the dura covered with villus granulations was at times markedly at variance with the normal temperature and apparent well-being. The eye grounds were almost invariably studied and in only one or two cases suggested involvement. The hearing was good, except as explained by peripheral conditions, and parietic or incoordinate symptoms were absent. Operation was invariably successful. The author includes notes of 5

very interesting cases. He believes that the antrum should be freely opened in acute cases, all of the tympanic cavities in the chronic, not only for drainage but for full inspection of the walls, and every portion of the decidedly suspicious bone should be curetted away. The operator need not fear reaching the inner table of the dura for the inspection of this part will frequently reveal further diseased conditions, and make the primary operation a success. [T. L. C.]

3.—James K. Young reports a case of **primary sarcoma of the spine**, in a Russian Hebrew child of 5 years who was first seen April 13, 1899, when a diagnosis of incipient Pott's disease was made. Under treatment great improvement followed in a fortnight. The patient was finally readmitted in February, 1900, and died in June of that year, of ashenia. No necropsy was permitted. From this case Young concludes that the characteristic symptoms are: **pain, paraplegia, grave constitutional involvement, rapid course and metastasis.** Metastatic growths occurred in the postorbital region of this child, but there were probably also growths in the liver and in all the abdominal organs. According to Edes the pain in sarcoma of the spine is not nearly so severe as in carcinoma, whether it be primary or secondary. It is increased on pressure, on standing or sitting up quickly or upon turning over in bed. The diagnosis may be made from a severe localized pain, the tenderness over the spine, and the rapid progress of the disease. An exhaustive study of the **differential diagnosis of primary sarcoma of the spine** from a host of other conditions is given. [T. L. C.]

4.—D. L. Edsall presents a critique of **certain methods of gastric analysis**, especially 4 of which may be used by clinicians for determining the total HCl of the gastric contents. These 4 are worthy of consideration are Leo's, Toepfer's, Hewes', and the one recently described by Cohnheim and Krieger. Leo's method is perfectly satisfactory in cases in which organic acids are absent, and if simply qualitative tests for lactic acids and for volatile organic acids are negative, it may be used clinically with entire confidence, remembering always that calcium chloride must be added to the stomach contents before the primary titration for total acidity is carried out. Edsall believes that **Toepfer's method** is of little value even for clinical purposes, because the color changes in the titrations are so difficult to recognize. One of the most serious errors in the employment of Hewes' test is the use of 3 indicators, thus multiplying the errors due to indicators. Cohnheim and Krieger's method depends upon the fact that phosphotungstic acid, and the salts of this acid, precipitate native albumins and the products of their digestion in combination with the phosphotungstic acid. This method in brief consists in the determination of the total acidity of the gastric contents, then adding to another portion of gastric contents a solution of phosphotungstate of calcium, which precipitates the albumin and albumoses and sets free the HCl in combination with them. The HCl combines with the calcium of the phosphotungstate and forms neutral calcium chloride. There occurs, therefore, a reduction of acidity corresponding to the amount of combined HCl present, and the combined HCl is at once indicated by titrating a second time after the precipitation and by determining the difference between the second and first titration. These authors report a series of results which they obtained with stomach contents controlling these results by **Sjoeqvist's method**, and also results obtained when working with known quantities of HCl in solutions containing Witte's peptone. Their results were strikingly accurate. Edsall believes that this method is more accurate than those which have been suggested with the possible exception of **Sjoeqvist's method**. [T. L. C.]

5.—Edward T. Reichert presents the results of **experimental work upon adrenalin**, the active principle of adrenal extract as a proposed agent in morphine and opium poisoning, in circulatory failure in the prevention of prolapse in anesthesia and in allied conditions. Reichert found while in normal dogs a dose of 0.00025 grams per kilo is without any decided effect upon general metabolism and body temperature, in morphinized dogs it is sufficient to prevent the profound decrease of general metabolism, and the marked fall of body temperature, caused by morphine. This marked difference is most interesting and adds evidence in favor of the view advanced as to the probable involvement in morphine poisoning of the processes contained in internal secretion, and the consequent import-

ant bearing of the action upon toxic phenomena. It suggests also that morphine acts as a direct depressant to the secretory processes of the adrenal glands, thus depriving the vital centers of the secretion with the resultant marked depression of both general and special forms of metabolism. In normal dogs very small doses are without effect, presumably because the quantity of adrenalin introduced is so minute as to be rapidly destroyed. The normal supply of adrenalin being sufficient, any quantity beyond this introduced into the blood and lymph being immediately destroyed, or compensated for, by an inhibition of the secretory activity of the glands; but in **morphinized dogs**, because of the blood lacking this proper constituent, **adrenalin is not destroyed** until it has been utilized in its normal work. The positive and prompt action of adrenalin upon the respiratory movement of the heart, arterial pressure, general metabolism and body temperature justify the belief that this substance will be found of value in opium and morphine poison and the conditions named in the title. It is probably owing to its powerful local action as a vasoconstrictor that abscess will be caused by subcutaneous injections. When administered by the stomach, in morphinized individuals, it should be given with alcohol in some form so as to increase the rapidity of absorption. [T. L. C.]

AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

1. Primary Splenomegaly. BRILL.
2. Enteoptosis. ARNEILL.
3. The Estimation of the Urinary Sulphates and of the Fecal Fat in the Diagnosis of Pancreatic Disease. EDSALL.
4. Premature Infants. ADRIANCE.
5. Contribution to the Study of Fatty Infiltration of the Heart Secondary to "Supercardial Over-Fatness. ANDERS.
6. Multiple Neuritis and Hematoporphyria Following the prolonged Ingestion of Trional. HART.

1.—The extraordinary interest of Brill's communication lies in the fact that 3 cases of an **exceedingly rare disease** occurred in the same family. The family history was absolutely negative; none of the parents, grandparents, or great-grandparents apparently had any similar condition. Six children were born in the family. The 1st and 4th are now in perfect health. The 2d died at the age of 3 years of chronic diarrhea; the 3d, 5th and 6th, all suffered from **enlargement of the spleen**. The youngest of these died at the age of 9 years; he had been sickly from his 3d year, and before death an enormous enlargement of the spleen was recognized. The oldest of these 3, now 34 years of age and married, at about the age of 22 noticed an enlargement of the abdomen under the ribs on the left side, which proved to be an enormous enlargement of the spleen. About seven years later she developed a tendency to sweating with development of sudamina. This, a year later became hemorrhagic, and the patient had numerous 'blood boils.' She also had 2 attacks of pleural effusion. The blood was always normal, in all respects. During an attack of typhoid fever the spleen became soft, but subsequently enlarged again. Later there appeared on the sclerae on the inner side of the cornea, a yellowish wedge-shaped patch. The organs of the thorax and the lower part of the abdomen are displaced by the enormous spleen, but the patient is otherwise comfortable and fairly energetic. There is also progressive emaciation. There have been no attacks of fever, no symptoms of renal disease, and the liver is apparently normal in size and consistency. The 3d patient, the 5th child, a man, discovered the existence of a slightly enlarged spleen at the age of 19. He was then suffering from sudamina; there were frequent attacks of epistaxis and an erythematous eruption about the nose. The blood was always normal. Drugs had no effect; the spleen enlarged progressively, and there have been hemorrhagic boils and some pigment patches on the skin. In neither patient has there been any enlargement of the lymphatic glands. There is moderate enlargement of the liver. The distinctive features of these two cases, both of which have been carefully studied by Brill are the enormous enlargement of the spleen, the moderate enlargement of the liver, the profuse perspiration, the sudamina, the hemorrhagic tendency, the peculiar brownish yellow coloration of the skin, and the absence of blood changes

for aperiod of more than 10 years. Both patients have the yellowish wedge-shaped patches to the inner side of the cornea on the sclera. The disease is evidently not due to malaria, syphilis, rachitis, nor tuberculous. It is not a form of amyloid disease, leukemia, Hodgkin's disease, or splenic anemia. Neither can it be due to abscess. The course has been too slow for malignant tumor; the absence of any condition that would give rise to possible congestion excludes this process, and the fact that the liver is not cirrhotic shows that the condition is not Banti's disease. It is therefore impossible to classify these cases at present. [J. S.]

2.—Arnell, discussing **enteroptosis**, states that Virchow first called attention to displacement of the intestines in 1853 [Morgagni preceded him by nearly a century.—J. S.] Glenard first suggested the relation existing between this displacement and certain complexes of clinical symptoms. In the examination of these patients the important points are: to determine the position of the stomach, the abnormal mobility of the 10th rib, and to palpate carefully the other organs. He prefers inflation for the determination of the stomach area, and usually employs tartaric acid and bicarbonate of soda taken separately. In 2004 cases of which he has records since 1892, he has found enteroptosis in 11 men and 69 women. In 24 cases both kidneys were dislocated; in 33 the right kidney alone; and in 4, the left kidney alone. Stiller's phenomenon was present completely in 8, and partially in 7 cases that were examined. The condition in the other cases was not recorded. In 69 of these cases the stomach was distended, and was more or less enlarged. The total acidity was apparently slightly decreased in some of the cases. In a few of them there was moderate chlorosis, and in several slight anemia. The majority of cases occurred between 20 and 50 years. The symptoms were chiefly those of neurasthenia, and in addition, poor appetite, coated tongue, nausea and vomiting, and chronic constipation. He reports a few cases, and in discussing treatment expresses his skepticism of the use of operation, but believes that nux vomica, hydrochloric acid and over-feeding are of great value. [J. S.]

3.—Edsall in a valuable paper upon **pancreatic disease**, reports 2 cases. The first, a man of 36, had pain above and to the right of the umbilicus, and subsequently rapid emaciation. There was absence of free HCl in the stomach contents, but none of the other chemical symptoms usually supposed to indicate carcinoma were present. There was slight tenderness on pressure in the epigastrium. Later he developed jaundice and very rapid emaciation. Estimation of the sulphates showed that the ethereal sulphates bore a relation of 1 to 20 or 30 to the proformed sulphates, showing that they were markedly diminished. An operation was performed and shortly afterward the man died. At the autopsy a carcinoma of the head of the pancreas was found completely occluding the biliary and pancreatic ducts. The author also reports another case of jaundice in which the ethereal sulphates bore a relation of 1 to 8 to the proformed sulphates, and pancreatic disease was therefore excluded. After discussing the literature, however, he reaches the conclusion that this sign is not of great value. It must be carefully considered in each individual case, and is only of importance when positive. In addition the fats were carefully estimated in the second case, and it was found that they constituted over 80% of the entire amount of the feces, and that a very small proportion of the amount of fats ingested, that is about 60%, has been absorbed. However, these fats have been split, that is to say, 78% was formed of fatty acid. It seems to show that mere absence of bile does not prevent the action of the fat-splitting ferments. Excessive amount of fat in the stools, however, does not of itself indicate pancreatic disease. [J. S.]

4.—Adrian discusses the **symptomatology and treatment of premature infants**. There is usually considerable disturbance of temperature, most commonly it is sub-normal, but occasionally irregular, or febrile. The children are very liable to attacks of cyanosis on account of the inefficiency of the respiratory centre and the partial atelectasis of the lungs. The kidneys sometimes do not act well, and there is often an excessive secretion of uric acid. There is a very marked tendency to the development of anemia. Weight is gained very slowly. The author has observed 40 cases in which the children were born anywhere from the 28th to the 38th week. Of these 24 died and 16 lived. All born before the 30th week died, although one of these lived to be 9 months of age. In fact 11 of the 24 deaths were due to complications and not to premature

birth, all of the 11 children surviving the period of full term. Of course the prognosis for life is graver the earlier the children are born. With regard to treatment the most important points are the temperature and the feeding period. The children should be placed in an incubator whose temperature is regulated according to their condition; lower if they have fever, and higher if their temperature is subnormal. The children should be left absolutely at rest and not even bathed, and the clothing should be readily removable. The feeding is a very important process. The milk obtained from a woman whose child is about a month old is most suitable for administration. It should be given with a dropper, remembering that the stomach capacity is not more than a dram or two. Attacks of cyanosis should be met by the administration of oxygen and whiskey. Constipation should be avoided by small doses of castor oil. [J. S.]

5.—Anders discusses **fatty infiltration of the heart**, and reports the following cases. A woman of 40, weighing 220 pounds, who had been in ill health for some time, and asthmatic, had delirium cordis. She was extremely nervous and from time to time had anginoid attacks that could only be relieved by morphia. She was evidently suffering from fatty infiltration of the heart. The second case, a woman of 50, weighing 310 pounds, suffered from extreme dyspnea, cyanosis and exhaustion on exertion. Appropriate treatment reduced the weight 125 pounds, and the patient recovered. It is possible that this was merely a case of fatty infiltration of the pericardium. He also reports several other cases in which reduction of weight caused very marked improvement in the cardiac symptoms. He has collected 7 cases from the literature in addition to his own. It is interesting that in many of these cases the fatal termination was due to rupture of the heart. [J. S.]

6.—A woman of 50 had suffered for 20 years from insomnia for which she took large quantities of trional. This treatment was interrupted, but subsequently she again commenced it. After a considerable interval during which she used the drug constantly, she developed pain in the abdomen, nausea, and vomiting. Later she passed red urine which gave the characteristic spectrum of haematoporphyria. There was then tingling in both arms, loss of both knee-jerks, hyperesthesia and reactions of degeneration in the extensor muscles of the arms. She had delirium with some hallucination, and subsequently extreme hyperesthesia of the skin of the body. The trional was stopped and she gradually improved, and subsequently recovered completely. It is important therefore to remember that trional can produce acute poisoning just as sulphonal does, that it has a cumulative action, and that while it is being given the kidneys and bowels should be kept active. [J. S.]

A Case of Ascites and Prolonged Fever as a Result of Syphilis.—A. K.

1901) reports the case of a man 34 years old who suffered from neurasthenia, ascites accompanied by marked enlargement of the abdominal veins, edema of the lower extremities, and an irregular fever characterized by chills, elevation of temperature and night-sweats. The paroxysms would last for two or more months, followed by an intermission. On examination both the liver and spleen were found enlarged. Altogether, this state of affairs existed for 4 years. Antimalarial as well as general treatment did not have the slightest effect, the patient getting progressively worse. Having obtained a history of syphilitic infection dating 10 years back, the author placed the patient on specific treatment. After the ninth injection of salicylate of mercury, the ascites the other symptoms promptly disappeared, except an obstinate periostitis of several bones. The author explains the ascites by the suppositio that the enlarged lymphatics of the hepato-duodenal ligament compressed the portal vein. [A. R.]

A Case of Malignant Syphilis.—Mironowitch (1901) had under his care a young man of 30 of good physique and family history who contracted syphilis, and despite vigorous and persistent specific treatment passed through practically the three stages of syphilis within seven months, his central nervous system becoming finally involved. The patient committed suicide while in a state of dependency. [A. R.]

PUERPERAL POLYNEURITIS AND POLIO-MYELITIS

By JAMES STEWART, M. D.

of Montreal

Professor of Medicine and Clinical Medicine, McGill University; Physician to the Royal Victoria Hospital.

Neuritis, either localized or multiple, is a well recognized condition, occurring either during pregnancy or within a short period after labor. The following case is an interesting example of polyneuritis coming on during pregnancy, and in which also a poliomyelitis existed, as well as changes in the posterior and lateral columns of the cord. The patient first came under observation on the 23d of August, 1900, complaining of tremor and numbness below the knees and elbows. She was a farmer's wife, 33 years of age, and the mother of five children. She was uncertain as to the exact time when she first experienced the numb feelings in her limbs, but is almost certain that they were present about two months before her labor, which was on the first of July. On the 23d of August, in addition to the numb feeling, she had a fine tremor of both hands, which eventually disappeared. At this time no distinct paralysis was evident, but the movements were slow. The tremor was increased on movement. On the 11th of September she was admitted into the Royal Victoria Hospital. In her past the most noteworthy medical events were: (1) Severe vomiting after the first and last pregnancies; this necessitated her remaining in bed 6 weeks on each occasion. (2) During the 2nd, 3rd and 4th pregnancies, vomiting, although severe and long continued, did not prostrate her to that degree that she was compelled to keep her bed. (3) During her childhood she had measles, chicken pox and scarlet fever. She lived always on the farm, and since her marriage, about nine years ago, her work has been heavy and prolonged. She also had much anxiety as to whether her husband and herself would be able to retain the farm. Her father and mother are living and in good health. Four sisters living, and all said to be in good health. One is hysterical. A brother died of pneumonia, and a maternal aunt of cancer. There is no history of tuberculosis in the family.

State on Admission, Sept. 11th, 1900.—She was a well nourished woman, of a neurotic temperament. Her weight was 114 pounds. She assumed the dorsal decubitus, but was able with considerable effort, to turn to either side. There was no gastrointestinal disturbance, except a slight tendency to constipation.

Nervous System. Sensorium.—Although emotional, the mental state was normal, and remained so up to the end. At no time was there complaint of headache.

Motion.—There was considerable loss of power in the muscles of both lower limbs, but in no single muscle, or group of muscles, did it reach an absolute degree. It was distinctly more marked in the most peripherally situated muscles, but not sufficient to produce a foot drop. The patient was able to walk the length of the ward, but with considerable effort. In both upper limbs a similar but less

marked paralysis was present, being, as in the case of the lower limbs, more marked in the distal parts. The extensors, although weaker than the flexors, were not paralyzed to the extent of causing a wrist drop. There was, however, no single muscle or muscular group in a normal state as far as voluntary power is concerned.

Sensation.—She complained of a constant and disagreeable sensation of numbness in the lower limbs and lower part of the abdomen up to about the region of the eleventh thoracic segment. There was no girdle sensation. The same abnormal sensations were complained of in the upper limbs to about midway between the elbow and shoulder joints. Sensation to touch was slightly lessened over both lower limbs, and on the trunk to nearly the level of the umbilicus. There was only a slight diminution over the upper extremities. The reaction to painful and thermic stimuli appeared to be unimpaired. The calf muscles were very tender on pressure, while the remaining muscles were only slightly so. There was no disturbance of the muscular sense in any of its varieties. Both knee jerks were normal. The plantar and pharyngeal reflexes were lessened. The abdominal reflex was normal. The organic reflexes of swallowing, micturition and defecation were not interfered with. The electrical reactions were not disturbed.

Sight.—The vision was normal, and no change was found in the fundi. The pupils were equal and active to both light and accommodation. The movements of the eyeballs in all directions were not interfered with. There was neither nystagmus or jerking on voluntary movements of the eyeballs. The other special sense organs did not present any sign or symptom of disease.

The pulse was persistently rapid throughout the course of her illness, ranging from 90 to 120. The respirations were also increased, ranging between 24 and 30, till within a few days of death, when, in consequence of the terminal pneumonia, they became still more rapid (45 to 50). The temperature throughout the course of the disease remained subnormal till the advent of the pneumonia, when it reached from 100. to 102°. The urine at all times was free from abnormal ingredients.

A Summary of the Course of the Disease, from her Admission, on Sept. 11th, till Death, on the 21st of November.—When admitted, she was able to both stand and walk, but with some difficulty. There was a slow but irregular, increase in the depth of the muscular weakness during the first month of her stay in the hospital. About the 15th of October, the paralysis in the lower limbs was absolute and general. In the upper limbs it was absolute in the distal parts, and approaching so in the more proximal areas. There was complete wrist and foot drop. Ten days after admission, both knee jerks had entirely disappeared. The great nerve trunks of both the upper and lower extremities were at this period very tender on pressure, as were also the muscles. The tenderness in the calf muscles was especially marked. She did not complain of spontaneous pain when quiet. About the first of October there were signs of intercostal weakness, but it was not till later that the diaphragm showed signs of beginning failure. About the middle of October, wasting of the muscles of the

extremities was observed, being particularly distinct in the calf muscles. Towards the end of October, for a few days there was apparent improvement, not only in the motor, but also in the sensory disturbances. On several occasions throughout the course of the disease, a similar but less marked amelioration in the symptoms led to a hope of a favorable termination. Such hope, however, proved to be false. There was on the whole soon after such changes, a deeper degree of disability, both motor and sensory, and nearly always evidence of extension upwards of the paralysis. On the 17th of November the diaphragm showed signs of failing, and the following day a pneumonia was detected, which proved fatal on the 21st. The onset, course and termination of this interesting case will be made clearer by a short epitome of the leading events.

A woman, aged 33, after suffering severely from vomiting, began to complain about the seventh or eighth month of her pregnancy of a sensation of numbness in the lower limbs, and shortly afterwards in the upper limbs. This was followed after a period of two months by a slowly increasing motor paralysis of all four extremities, which progressed to practical total disability. The paralysis was of the ascending type, and finally involved the respiratory muscles. The sensation to touch was diminished, but not lost, while the reaction to painful and thermic stimuli was retained. The knee jerks were lost, as well as the plantar reaction. The abdominal reflex was retained. There was considerable muscular atrophy, but no disturbance of the organic reflexes. At first the electrical reactions were normal, but afterwards there was lessening of the Faradic reaction, showing the middle form of the reaction of degeneration. (A full examination of the electric irritability was not carried out, owing to the pain induced.) A pneumonia, chiefly owing to the previous parietic state of the respiratory muscles, ended the scene two and one-half days after its onset.

Autopsy One Hour and a Half after Death: by Dr. Adami.—Body of a middle aged female, fair size, rigidity just beginning, lividity moderate in dependent parts; body still warm, nutrition fair, pupils equal and moderate in size; orifices of body normal; breasts normal; some roughening of the skin over the front of abdomen. There was a slight, smooth scar on the anterior and inner surface of the left thigh. Feet in position of complete ankle drop, skin over the dorsum of feet puffy in appearance and slightly desquamating, probably an atrophic change. Muscles everywhere extremely flabby, especially those of the arms and legs.

Thorax.—Both lungs free from adhesions; left lung 290 grms., only slightly pigmented; apex showed some compensatory emphysema, lowest lobe completely collapsed, pleural surface near great fissure in both lobes somewhat raised and granular looking and covered with a thin layer of fibrinous lymph. The anterior edge of the lowest lobe, near fissure, was consolidated and somewhat friable. The upper lobe, a long, narrow strip extending almost the whole length of the great fissure, was consolidated, airless and friable, on section of a greyish granular appearance. Condition of diffuse pneumo-

nia in grey hepatization stage; condition found to be somewhat patchy; possibly it started as a bronchopneumonia. Bronchi somewhat reddened, contained somewhat sticky mucus; pulmonary vessels free.

Right lung, 340 grms.; slight compensatory emphysema of the upper and middle lobes; pleural surface of the lowest lobe, somewhat granular, covered with flaky lymph; upper third of lowest lobe swollen and firm, on section rather dry, consolidated, in a state of grey hepatization, condition more uniform than in other lung. Lowest third of lowest lobe completely collapsed; bronchi and pulmonary arteries as before.

Smears from consolidated area showed numerous bacilli of unknown form and an occasional micrococcus lanceolatus.

The other organs of the body showed nothing markedly abnormal, but showed a marked tendency to congestion.

The Microscopical Appearance of the Lungs.—The parts which are not so much consolidated are much congested, the bronchi show marked acute bronchitis, the lumen being filled with exudate, the alveoli of the lung are for the most part filled with an inflammatory exudate, consisting of leukocytes with occasional red cells and fibrin. The inflammatory exudate is irregular in intensity and somewhat patchy; certain other of the alveoli contain relatively few leukocytes, but a great deal of fibrin and some again filled for the most part with red cells; one or two small hemorrhages were noticed.

Examination of the Nervous Structures.

By Dr. Shirres.

The brain, spinal cord and ganglia were removed for examination, also both sciatics, musculo-spirals, anterior crurals, peroneals, anterior tibials and their end ramifications, pneumogastrics and phrenics. The peripheral nerves, certain parts of the brain and of the cord at different levels, were placed in Mul-

Figure 1.

Transverse section of the Anterior Tibial Nerve showing the endoneurium and separation of the connective tissue by the third extension.

ler's fluid, while the remaining sections were at once placed in alcohol for Nissl's stain.

Peripheral Nerves, Cord, etc.—Naked eye changes.—All the peripheral nerves were found markedly swollen and of a reddish yellow color, especially so the sciatics and anterior tibials, which were at least twice their normal size and seemed to be very edematous. The internal plantar was about the ordinary size of a normal sciatic nerve. Cord and spinal ganglion cells appeared normal. After thorough fixation and hardening of the different parts, sections of the cord and peripheral nerves and spinal ganglia were imbedded in celloidin or paraffin.

The methods employed were (1) Weigert-Pals' hematoxylin, (2) Van Gieson's hematoxylin and eosin, (4) Marchi's osmic acid, (5) Nissl's methylene blue method.

Peripheral Nerves.—Longitudinal and transverse sections were made, the latter being by far the most instructive. The changes found may be summarized as follows: Marchi's method of investigation showed the distinctive signs of a true parenchymatous degeneration. Under a low magnifying power the nerves are seen to be studded with black granular spots, with the higher power the dark spots are seen to be sections of degenerated nerve fibres, in some places two or more being blended into large masses. Scattered irregularly among those degenerated fibres, in every bundle more or less, are to be found normal healthy fibres.

Hematoxylin and Van Gieson's method revealed that along with the parenchymatous degeneration there was also marked interstitial inflammation, the blood vessels being distinctly distended, thickened, and with numerous small hemorrhages in the epineurium and endoneurium; also a distinct sero-fibrinous exudate and leukocyte-like corpuscles and spherical cells surrounding the vessels and infiltrating the sheaths and interstitial tissue between the fasciculi and a few in the substance of the fasciculi between the nerve fibres. The lymph spaces between the laminae of the perineurium were markedly distended. The nuclei of the cells of the endoneurium were very evident on longitudinal section and were in greatly abnormal numbers. All the nerves examined showed the changes above described, more or less; it was noticed that the further away from the cord, the condition of a simple parenchymatous degeneration was more marked. The pneumogastrics and phrenics, like the above, did not suffer so much from interstitial changes, but showed more of the parenchymatous condition, the degenerated fibres being clearly demonstrated by Marchi's method.

Cord Changes.—White Matter: Sections of the cord that were hardened in Muller's fluid and treated by Marchi's method showed a scattered degeneration in the position of the posterior columns, involving both Goll and Burdach's tracts in the lumbar region. In the cervical region the degeneration was confined to Burdach's column. Degenerated fibres could also be seen in the lateral region of the cord (direct cerebellar tract) in the upper dorsal and cervical regions. Upon examination of the posterior roots, along the whole length of the cord, degenerated fibres could be seen—Lissauer's column being dis-

tinctly affected. No changes could be detected in the anterior roots.

Van Gieson's or the hematoxylin method did not reveal anything like a condition of lepto-meningitis or myelitis of the cord or membranes. Sections of the cord that were fixed and hardened in alcohol and stained by Nissl's methylene blue method, revealed marked and advanced chromolytic changes of the peripheral central and perinuclear varieties, in the ganglionic cells of the grey matter, more especially in the anterior horns and Clark's columns. The most advanced changes, even on to complete atrophy and disappearance of cells, were to be noted in the cervical cord in the region of the 5th, 6th, and 7th

Figure II.

Ganglionic Cells of the Anterior Horns in the Lumbar Cord, showing displacement, etc., of the Nucleus and Chromatolysis.

cervical segments. Here, as above stated, there was a marked numerical lessening in the number of cells compared to the normal condition in those situations; also, there was a marked difference between the right and left anterior horns, the right containing hardly any ganglionic cells at all, the few that were present were simply atrophied shreds. The other ganglionic cells of the grey matter did not present such a picture of atrophy, but all more or less showed marked chromolytic changes. The lumbar and lower dorsal regions were affected in a minor degree compared with the cervical. The changes were essentially polymorphous, every grade of chromatolysis was seen from where the cells were swollen or spherical with the protoplasm undergoing alterations, and showing chromatic bodies normal in amount and situation, to stages in which these were distinctly granular or gave a condition of a diffuse stain, and finally to a condition in which the cell body was very pale and did not present any chromatic particles, or protoplasmic processes and the nucleus was absent or eccentric.

Spinal Ganglion Cells—Nissl's Method.—The spinal ganglion cells did not show any marked alteration, but there was present a marked increase and

proliferation of the cells (which looked like an inflammatory reaction) of the capsule surrounding the individual ganglionic cells.

The clinical course makes it highly probable that we had to deal, first, with a neuritis, and later with a localized myelitis (poliomyelitis). The symptoms were, for several months, those of a neuritis, rather than a poliomyelitis. In fact, at no time were there sufficiently distinctive symptoms present to enable one to say definitely that the spinal cord was involved. It was only the gradual ascending character of the paralysis (Landry type) that some three or four weeks before death gave a clue as to a probable spinal involvement. The development of the symptoms and the appearances met with in the nerves makes it clear that we had to do in the first place with a parenchymatous neuritis. The prolonged primary stage of numbness in all the four extremities, together with a prolonged period of simple weakness of the peripheral muscles pointing to a distal parenchymatous multiple neuritis as the primary lesion. Dr. Shirres refers to the fact that with the Pal-Weigert stain he was able to obtain a much clearer view of the degenerated fibers. The axis cylinders seem to have in many places disappeared when this stain was used, while with the Marchi stain a much less degree of degeneration was noticeable. He explains this by referring to the established fact that the Marchi stain gives more clear results if the degeneration is recent (6 to 10 weeks), while the Pal-Weigert shows more definite changes in older cases. The disease was probably upwards of 6 months' standing, and therefore the changes showed more clearly with the Pal-Weigert stain. The ultimate cause of the neuritis is not clear. The bacteriological examination of the nervous structures was, unfortunately, neglected, although cultures were taken at the time of the post-mortem examination. All the common causes of neuritis were absent, as lead, alcohol, acute and chronic infectious diseases, septicemia, etc., etc. What, if any, relation existed between the severe vomiting (pregnancy) and the neuritis, I have no evidence to show. A number of cases of puerperal neuritis have been reported, in which vomiting had been very severe, and the only marked feature present. Dr. Whitfield, in the *Lancet* (March 30, 1889), gives an account of such a case. Dr. E. S. Reynolds (*British Medical Journal*, vol. 2, 1897, p. 1080), narrates a case of paraplegia after labor, which he attributes to a peripheral neuritis, and in which abortion was performed on account of vomiting. He refers to a view held by Clifford Allbutt, who looks upon the vomiting of pregnancy as due to a toxin, and that the same toxin may induce a neuritis. In the considerable number of cases of multiple neuritis of puerperal origin, very few have been reported in which the onset occurred during pregnancy, nearly all being instances of post partum neuritis, which usually is attributed to sepsis. It is worthy of note that the changes in the spinal cord are not limited to the cells of the ventral horns, but that we have also a similar breaking down in the cells of Clarke's columns, and, as a result, a degeneration in the cerebellar tracts in the lateral cord. Although no degenerative changes were found in the proper structure

of the spinal ganglion cells, the posterior columns show considerable areas of degeneration (see Fig. III). In using the term "ascending paralysis," it should be understood that it is meant purely in a clinical sense, and not as signifying that the degeneration spread gradually up the cord from the peripheral nerves. It is much more probable that the poison affected the cord and peripheral nerves separately, and not that the peripheral changes caused the spinal changes by extension

Figure III.

of the spinal cord, showing the extent of the degenerative changes in the posterior columns and lateral columns.

from the periphery to the center. Further, it is still less likely that the central changes were the direct cause of the peripheral degeneration. The fact that the anterior-intra-medullary nerve roots did not show any signs of degeneration is evidence in favor of there being no direct causative relation between the central and peripheral changes.

I am indebted to Dr. Adami and Dr. A. G. Nicholls for the report on the general post-mortem examination, and to Dr. D. A. Shirres for the care and time he has taken in making a full and thorough examination of the spinal cord and peripheral nerves; and also to Dr. Hugh Patrick for the care he has taken in developing the photographs.

Literature on Puerperal Polyneuritis.—To anyone especially interested in this subject, the following articles will prove to be very valuable: 1st, J. Hendrie Lloyd, in the *Twentieth Century Practice of Medicine* (Vol. XI.), has a very exhaustive article on the whole subject of neuritis, and much attention is directed to both the local and generalized neuritides connected with the puerperal state. 2d, Professor Eulenburg (*Deutsche Med. Woch.*, 1895, Nos. 8 and 9), has a valuable paper on 38 collected cases of puerperal neuritis, being chiefly instances of the local (traumatic) form of the disease. A synopsis of the chief symptoms in all the cases is given. 3rd, Mobins (*Neurologische Beiträge*, Heft. 4, p. 24), who was the first to give a description of puerperal neuritis, gives details of his own cases (chiefly local form) and others. 4th, C. K. Mills (*Univ. Medical Magazine*, Vol. 5, p. 508). A valuable article. 5th, E. S. Reynolds (*British Medical Journal*, Oct. 10th, 1897), reports two cases, both paraplegic in distribution. He was able to collect 17 cases, not including any reported on by Eulenburg. 6th, H. M. Thomas (*Johns Hopkins Hospital Bulletin*, Nov., 1900). Chiefly dealing with the localized forms of puerperal neuritis.

LOCALIZATION OF SOUND AND ITS BEARING ON HEARING—ESPECIALLY IN UNILATERAL DEAFNESS.

By B. ALEX. RANDALL, M. A., M. D.

of Philadelphia

Clinical Professor of Otology in the University of Pennsylvania, etc.

The attempt has been made to map the field of hearing in a manner analogous to that of vision; but the essential difference must not be lost sight of, that sound-waves are not like light-waves propagated only in straight lines. The eye can take cognizance only of that which lies in front of the plane of the iris, and is further restricted by the prominence of the nose and the orbital margins. Its field, therefore, is sharply defined. The relative field of good hearing has some comparable limitations, as has been worked out by Ogston (*Med. Press and Circ.*, June 18, 1890); but it is probable that great individual variations exist, and that for different sounds the fields may vary even more markedly than the color fields of the eye. The absolute field of hearing is hardly definable, however, for not only can both ears hear sounds in the sagittal plane of the head, but, to a considerable extent, in each other's fields. Hence the great difficulty of excluding one ear from cognizance of tests directed to the other, and the need for such differential tests as have from time to time been brought forward. With all of this otologists are familiar, and they generally take these matters into practical account; but the effect upon the good ear of deafness of the other is not fully, if at all, considered. To have a deaf side is generally recognized as awkward, even when the other ear is perfect and suggests no likelihood of sharing the same fate. We meet many reports also of cases in which successful treatment of the worse ear has given notable gain of the other, which had no share in the intervention; but the rationale of this has rarely been explained with any plausibility or fulness. A brief note upon the matter seems in place, therefore, if only as a means of directing attention to a neglected but important series of phenomena.

In hearing, with both ears good, there should be little difficulty in localizing many, at least, of the sounds that come to us. Not only are they lateralized, but the other factors as to their direction can generally be sub-consciously determined. This is a matter of differential impression and analysis, for which an appreciable time is requisite; and very brief sounds may greatly puzzle us both as to their localization and interpretation. Ordinarily, we have sufficient continuity of impression to be able to follow intelligently one or more series of sounds, ignoring those interruptions which often intrude, since we can so readily recognize them as irrelevant. We form our mental concept of them from their quality, loudness and direction, aided generally in large measure by our concomitant visual impressions, but also in no slight degree by some subtle appreciation of their reflection from adjacent surfaces. This is much as we can locate a distant conflagration by a sort of triangulation in noting the direction and distance of buildings from which its light is reflected. Our drumheads can respond to and convey a vast number of coincident sound-

waves to a deeper acoustic apparatus, which then takes cognizance of their pitch and volume, the latter having probably some slight dependence upon the form and position of the external ear. The rest of the analysis and appreciation is solely a function of the sensorium. Cognizant of such differences in the sounds assailing us, we may be able to hold the attention concentrated upon those which we wish to hear amid a babel of irrelevant noises, undisturbed unless we permit our thoughts to wander. One ear is often given to the sounds engrossing us while the other merely keeps guard-hearing, yet giving no heed to the sounds upon that side and even almost automatically side-tracking those on the busy side, which might confuse its task.

The condition is very different when one ear must act alone, unaided by its fellow. The physical problem is little changed, and the auditory apparatus receives and transmits to the percipient centers the same range of sounds coming from practically all directions; but the psychic task is far more complex. One side of the brain to a much greater extent than usual, has to receive and analyze all the impressions, and these lack that element of double yet diverse character which in vision we call stereoscopic. Yet all acknowledge the huge importance for many purposes of this factor in the everyday use of our sight, in which, as we have seen, the problem is far simpler. With the eyes we recognize the apparent increase of illumination afforded by the superposed images of binocular vision and work with far less fatigue when the eyes thus supplement each other and distance, direction and object are practically unchangingly simple. With the ears we have no strain of accommodation or convergence (which should be no burden to healthy eyes), but the absence of these functions leaves us devoid of any such ready means of determining the distance, and hence many other characteristics of the objects of our attention, and throws the more work upon the interpreting faculties. Few persons make any success of fixing by a brief glance, any considerable number of articles, so that they can later enumerate or describe them; yet this, with a presumed "sense of the context" as our only aid, is what is continuously demanded of the hearing. Rotation and other movements of the head can, as in binocular vision, furnish some localizing factors; yet the problem remains too largely a mental one, and the "fatigue of the deaf," of which Dr. Blake so well speaks in the Introduction to Gorham Bacon's Manual, is by no means absent in those who, with one perfectly good ear, are often unrecognized by their companions as having any lack. Some of them are themselves as surprisingly unconscious of the defect, as are some who have grown up in ignorance that one eye is virtually sightless; but this is usually rather a matter of unilateral deafness for certain sounds only, such as the tick of a watch, which are often very unequally heard by ears supposedly normal. Yet it is full time that the value and importance of "binaural hearing" should be more fully recognized, and that due care be exercised to retain or secure it in those who are really, if unconsciously, suffering for the lack of it.

THE GERMAN CLINICS OF TO-DAY.

By JOHN C. HEMMETER, Phil. D., M. D., Etc.

of Baltimore, Md.

Professor in the Medical Department of the University of Maryland, and
Director of the Clinical Laboratory.

About thirty years ago the methods of scientific diagnostic investigation which had been inaugurated in Vienna by Rokitsansky and Skoda, had taken root firmly in Berlin, and had been further developed by Virchow and Traube. Pathological anatomy not only led the advance and assigned the guiding line for clinical diagnosis, but the deductions for therapeutics were also based upon the evidences furnished by this science. Experimental physiology and experimental pathology were also sciences influencing the tendencies of clinical medicine. This was a glorious and epoch-making period in the history of clinical diagnosis. Unfortunately, however, some of the skepticism and nihilism of the Vienna school had gone along with the advancement, the diagnosis was held up as the main object of the clinician; but the actual therapeutics, what could be done to control, check and remove the disease, was passed over and neglected. Expectant therapeutics, to observe, not to injure, those were the motives.

The treatment of disease was not entirely neglected, but the therapeutists placed their hope in the future, and had no confidence in the methods of the present. There were many ironical allusions to the helplessness of internal medicine when it was put to the test of relieving suffering or healing a disease. Among the practitioners there prevailed a spirit of pessimism. Such must inevitably be the case when the practical therapeutic duties of clinicians are subjected to too rigid a scientific criticism, based upon the ideals of pathological anatomy. The objects of therapeutics could not be accomplished; our methods to help and to heal could not be improved, if we were to be guided exclusively from the lessons of autopsies. Therapeutics must reckon with the result of approved experience, also, and must help and heal according to the measures which are at their disposal at any one time. We cannot console the suffering patient with promises of remedial discoveries of the future. This truth, once recognized, therapeutics was freed from the spell under which too rigid a scientific criticism had placed it to the disadvantage of practical results for the patient. Up to that time the motto was "to cure diseases." This was transformed to the devise, "To make the diseased well," or "To heal the patient." These two mottoes do not represent a "distinction without a difference," for by saying "To cure diseases" we refer by the name "Disease" to whatever abstract conception of a morbid condition may prevail in the medical mind at any given time. Such conceptions have differed greatly concerning the same disease at various times; and accordingly the treatment necessarily differed also. It was greatly to the merit of Von Leyden to emphasize the difference between attempting to cure a disease and attempting to heal a patient. By healing a patient we mean relieving him of his suffering, healing his morbid condition, independently of what

our conception of the disease may be. In the one case we are dealing with the abstract formulation of symptoms known as a "disease," and based upon the alterations pointed out by pathological anatomists, too apt to be manipulated categorically and dogmatically. In the other case we are dealing with the many varieties of human individuality as they are influenced by abnormal states. Modern therapeutists are not satisfied to study the disease process and its course; the physician must also familiarize himself with the special manner in which disease manifests itself in, and influences the individuality of each and every patient. The personality of the patient is put in the foreground of treatment, not the conception of the disease. This is one of the predominant features of the therapeutics in the German clinics of to-day. It probably had its origin in the great discovery of Lister, and the impulse it has given to modern surgery. Then came the suggestion to the internal clinicians: "You must become surgical also," and as much as possible internal therapeutics has attempted to follow out this suggestion. Under the direction of that scholarly medical philosopher, Naunyn, a journal is published on the border districts of disease lying between internal medicine and surgery, much to the advantage of both these branches.

Another feature of the German clinics is the tendency to make use of a large variety and many methods for the relief of suffering and to cure disease. Pharmacy, i. e., medicines and the improvement. These two mottoes do not represent a "distinction without a difference," for by saying "To cure diseases" we refer by the name "Disease" to whatever abstract conception of a morbid condition may prevail in the medical mind at any given time. Such conceptions have differed greatly concerning the same disease at various times; and accordingly the treatment necessarily differed also. It was greatly to the merit of Von Leyden to emphasize the difference between attempting to cure a disease and attempting to heal a patient. By healing a patient we mean relieving him of his suffering, healing his morbid condition, independently of what

First came the evolution of so-called specific remedies, based and inspired by the cure of hydrophobia by Pasteur; Koch brought out his tuberculin; Behring the diphtheria anti-toxic serum. Then followed similar serums for the treatment of tetanus, the plague, cholera, and the pneumonia antistreptococcic serum. But even where there are no specific remedies, the efforts are persistently made to restore health to the patients. The therapeutics of the disease, of the localized pathological process, may, in some cases, have to continue to be expectant, but the treatment of the diseased individual must, nevertheless, be active and systematic. Frequently a sick individual may be aided in overcoming the disease by the thoughtful and logical application of a number of apparently insignificant means and methods. The patient is helped through the danger of the disease. As Thos. Clifford Allbutt puts it, "The physician learns to play a winning game against the disease." Next to the actual treatment by drugs, medicines, etc., the German clinic has wonderfully evolved the method of treatment by diet. In no other civilized nation in the world are diet treatment or nutritional therapeutics made the objects of thorough scientific investigation as in Germany. There are two journals which make the dietetic treatment one of the chief reasons for their publication. Boas' "*Archiv für Verdauungs-krankheiten*" (Archives for Digestive Diseases), and Leyden's "*Zeitschrift für Diätetische und Physikalische Therapie*," and a third journal exclusively devoted to methods and means that add to the comfort of the sick (*Die Therapie der Gegenwart*). Right here I desire to emphasize the necessity of such a journal in our country. We need

*Address before the Medical and Chirurgical Faculty of Maryland

a journal of high scientific standard, which will be the depository for all investigations and observations, clinical, experimental and pathological, concerning the treatment of disease by diet and physical methods. It will be a poor consolation to suggest to us to utilize the already existing German journals for that purpose. In the first place, very few of our American practitioners understand German sufficiently to derive any benefit from these journals, and in the second place, our American digestive organs are sufficiently different from the German, our diet a more manifold and peculiar one, our habits greatly at variance with those of the Teuton, to make such a journal edited from the American standpoint a great desideratum. Moreover, many of our foods are unknown in Germany. Our beverages have an entirely different chemical composition. Even the amount of proteid, carbohydrate and fats in the more commonly used solid foods differ from those used in Germany.

Among other newer tendencies issuing from the German clinics is the participation of internal medicine in the humanitarian and social duties of our present age. This is the sphere where prophylaxis becomes active. This tendency found its expression in the International Congress for combating tuberculosis, as a collective disease. I would urge upon the profession the expediency of a Congress to design methods and means for the study and relief of malignant diseases in this country, which are alarmingly on the increase. Large expositions have been held in Berlin exhibiting everything that is employed for the cure of disease, but more particularly for the care and comfort of the sick. I could not mention all the practical little devices seeking to improve the condition of patients, improved bed clothes, practical devices in dishes, cups, feeding tumblers and tables to be extended over the sick bed, both for feeding and entertainment, improvements in the construction of the bed itself, in bandages, urinals, thermometers, expectoration cups, gastric, rectal, colon and vesical irrigation, etc.

Great interest is manifested in hydro-therapeutics, also in aero-therapeutics, the treatment by hot and cold air, by gymnastics and massage. The representative German internal clinic of to-day is no longer under the ban of pathological anatomy, but its highest aim is the perfection of treatment, to help and to heal. Naturally, an exact diagnosis is essential to correct treatment; it is not now equally harmless and insignificant, whether we are right or wrong; since we are no longer supinely and helplessly carried down the stream of pathological events, but feel ourselves capable of buffeting at least with its waves, or perhaps of riding triumphantly over them; for why should we despair that the reason which has enabled us to subdue all nature to our purpose, should (if permitted and assisted by providence), achieve a more difficult conquest, and ultimately find some means of enabling the collective wisdom of medicine to bear down those obstacles which individual shortsightedness, selfishness and passion, oppose to all sanitary and prophylactic improvements, and by which

the highest hopes are continually blighted, and the fairest prospects marred?

After all that can be said of the benefits the human race derives from other sciences, medicine remains the most blessed of them all. Its theories and lessons may, it is true, occasionally baffle the medical mind in the sphere of conduct, as part of an order of things, too vast to be more than partly understood. Medicine, indeed, presents some difficulties which perplex the intellect, and a few, also, it cannot be denied, which wring the heart. But on the whole, the progress in medical science is in harmonious relation with the human spirit, and it shows at the present day a more enduring progress than any other science. Different from these, medicine has not passed its zenith; it does not point centuries back to the life and work of its great men; they are here, living with us at the present day, our contemporaries, and the prospects are that the future will produce medical men equally as great who will solve for us the riddles of the nature of syphilis, the cause and cure of cancer, the biology of the bacteria, and why it is that they cause certain diseases. From out the dim future these problems to be solved and our suffering fellow-men call to us. "Work and despair not."

1734 Linden Ave.

VOLVULUS AND INTUSSUSCEPTION OF MECKEL'S DIVERTICULUM.

By JOSEPH McFARLAND, M. D.

of Philadelphia

Professor of Pathology in the Medico-Chirurgical College, Pathologist to the Philadelphia and Medico-Chirurgical Hospital, etc.

The patient in whom the following case occurred, died in the wards of Blockley Hospital, with symptoms partly attributable to intestinal obstruction, partly to uremia, and became of interest only at the subsequent pathological examination:

Necropsy.—Body of a somewhat emaciated middle-sized man of about 60-65 years of age. Nothing of interest upon the exterior of the body except a lipoma the size of a pea upon the inner aspect of the left foot just below the inner malleolus. From the mouth a discharge of frothy, bloody fluid has occurred. Death 12 hours ago, rigor mortis well marked. Body cold. Usual incisions made to reach the organs. Costal cartilages not calcified. As the parietes were turned back, the abdominal cavity was found to contain about a liter of purulent fluid. The surface of the intestines was dulled, and there were numerous deposits of fibrinous lymph by which the different links of intestine were glued together in places, and on the left side to the abdominal wall. The great omentum, which was congested, was drawn up like a fringe along the transverse colon. There was an incomplete external inguinal hernia on each side, that on the right being larger than that on the left. Both contained a single knuckle of small intestine, which drew out with ease. The vermiform appendix was small in size and short. It was normal except that it had a peculiar acute angle at about its middle. It contained no enterolith, and was not adherent to the neighboring parts. As the bowel was examined, it was found that an obstruction occurred in the ileum about two feet above the cecum, where a peculiar

knotty twist was observed. This will be considered under the head of "intestines."

Thorax.—The left side of the chest contained about 500 cc. of blood-stained fluid. There were no pleuritic adhesions. The pericardium was normal, and contained a normal amount of normal fluid.

Heart.—The heart was of normal size. The right side and its valves were normal, the auricle probably somewhat dilated. The left chambers were probably slightly dilated. The endocardium of the left ventricle was thickened and opaque and obscured the muscular substance below. The mitral valve showed thickening of both leaflets and the chorda tendinae were thickened. The valve contained a few yellowish atheromatous patches and was dotted with red areas as if blood had irregularly infiltrated into the tissue. The aortic valves were slightly thickened. The coronary arteries were not sclerotic. In the aorta a small amount of atheroma was present, but the ascending aorta was widely dilated and seemed thinner than normal.

Lungs.—Both lungs showed inflation of the upper lobes and congestive edema of the lower lobes.

Abdomen.—The *spleen* was of normal size. Its substance was very soft and flabby, and the organ was so lacerated as to be torn in removal. The capsule was thickened, and there were several deep scars upon the surface resembling those left by old injuries. Section showed the substance of the organ transformed to a reddish pulp. *Adrenals.*—Normal.

Kidneys.—*Right.*—Considerably larger than normal, pale yellowish in color, flabby in consistence. The capsule strips readily. Upon the surface there are several deep depressions suggesting the loss of tissue seen in anemic infants, but not accompanied by fibroid changes. The pelvis and ureter are dilated. There were a few superficial cysts. *Left.*—This kidney is much larger than the right, and is also in the advanced stages of chronic parenchymatous nephritis, with fatty change. The pelvis and ureter are both dilated. *Bladder.*—The organ is contracted. Its shape is pyriform, the fundus forming the narrow part of the pear. The walls feel so thick, and the organ so filled with solid matter that a neoplasm was suspected. When opened, however, it was found that there was an enlargement of the middle lobe of the prostate, and chronic cystitis. The obstruction of the urethra by the prostate probably explains the hydronephrosis that existed. *Duodenum and Gall-Ducts.*—

Normal; the ducts patulous. *Gall-Bladder.*—Contained three ordinary calculi the size of small cherries. There was no cholecystitis. *Liver.*—Normal. *Pancreas.*—Normal. *Stomach.*—Normal. *Large Intestine.*—Normal except for the inflammation of the serous surface. *Small Intestine.*—This organ was the seat of the interesting observation already mentioned. When this was torn loose from the numerous plastic adhesions found about it, it was found that a Meckel's diverticulum about 4 centimeters in length was rotated upon its long axis about one quarter of a circle, and then invaginated for about two centimeters into the ileum, producing an obstruction that reduced the lumen of the intestine to about one-third or less. The intestine was quite empty, so that it is probable that the obstruction

has at no time been complete. By what force the Meckel's diverticulum ever became so twisted and invaginated, is difficult to conceive. The intestinal obstruction observed before death and the peritonitis with purulent exudate to which death was in part due, depended upon the intussusception. The deeply congested and swollen state of the invaginated tissue indicate that had death occurred a little later, gangrene of the bowel would have occurred. This case adds one more to the already long list in which Meckel's diverticulum has been responsible for intestinal obstruction. In addition to the obstruction, the intestine presented at about the junction of ileum and jejunum a lipoma the size of a peach stone attached by a short peduncle. There was also a single small body the size of a pea, loosely attached to the peritoneal surface of the small intestine. It was dark in color, matted in appearance, and more closely resembled one of the scattered peritoneal nodules seen in abdominal neoplasms than anything else. It was, unfortunately, lost before microscopic study could be made. As there was no primary neoplasm elsewhere, it may have been a primary neoplasm of the peritoneum, possibly an endothelioma. Unless the condition of the kidneys precluded the possibility of operation and spinal anesthesia was out of the question for some reason, the case could easily have been relieved by surgical operation. Probably, however, the symptoms presented were so vague that a correct diagnosis was impossible, and had the symptoms of intestinal obstruction been complete, the existence of two hernias might have further confused the surgical diagnosis.

DEATHS FROM ANESTHETICS.

By D. H. GALLOWAY, M. D.

CHICAGO.

Three deaths from anesthetics have occurred recently in Chicago, all within a period of ten days. This statement is both startling and disquieting to any one who makes much use of anesthetics, either as an operator or as an anesthetizer. The daily press has noticed two of these cases, but I have seen no mention of them in any medical journal. The profession regards them with an apathy which seems borne of a belief that they are inevitable, and that there are no means at hand for lessening the numbers of such deaths. A prominent surgeon said to me the other day: "A few years ago the dread of the surgeon was sepsis, and that caused most of the deaths; but now the anesthetic has taken the place once occupied by sepsis." I hardly think the majority of physicians or surgeons will entirely agree with him, yet there is some foundation for the opinion. Sepsis can now be almost absolutely avoided, but the danger from anesthetics does not seem to be in the least diminished. It seems that in our present state of knowledge no human foresight or skill can prevent occasional fatal results from anesthetics. It may be that these three cases were all of the unpreventable kind; but most of us know that of all surgical procedures the administration of anesthetics receives the least amount of attention and skill. Thousands of patients are

anesthetized every year in Chicago by persons wholly devoid of skill in the use of these agents, who are unable or unwilling to give to the work the amount of attention that is given to every other surgical procedure by every one making any pretensions to surgical skill.

A few weeks ago I was in an operating room, as a spectator, and saw chloroform given in a careless, off-hand manner; I turned to the surgeon, who was waiting in another part of the room, and said to him that if I should administer chloroform as it is being administered there, I was sure I should kill every patient I tried it on. While we were talking, the patient stopped breathing, and we were obliged to spend several anxious minutes in bringing him back to life. On another occasion I was present to assist at an operation, and advised two or three times that the chloroform be stopped to prevent what I believed was going to be a collapse of the patient from the anesthetic. The anesthetizer afterwards made some very caustic remarks about what he considered officious interference. A few days later, while assisting at another operation at which everybody but the operator was wholly unknown to me, I saw the anesthetizer giving chloroform and talking to nurses and others standing about, apparently only looking at the patient occasionally. We had scarcely begun the operation when I noticed the patient's condition was bad. I hesitated to interfere, but I could not refrain from calling the anesthetizer's attention to the patient's condition, and advising the removal of the chloroform; he removed the mask, and after watching the child for a few moments, said: "Why, he's all right," which was true. After a few inspirations of fresh air, he revived, and the mask, chloroform, inattention, and conversation were resumed. In less than five minutes I saw that the child was again being overwhelmed by the chloroform. I again suggested to the anesthetizer that he stop the chloroform for a little while. He did so, and after watching the patient while he took half a dozen more inspirations, he said with a scowl and in an impatient tone: "The child is all right." The chloroform was reapplied, and in two or three minutes more the child stopped breathing. I noticed this, though the anesthetizer did not. I called the surgeon's attention to the patient's condition, and he asked the anesthetizer whether the child was breathing. The anesthetizer slowly removed the mask, and after watching the patient for a time which seemed to me interminable, slowly said: "Why—I—don't—believe—he—is." After another apparently long time, and without moving, he said, with great deliberation: "Ought we to do something?" With this I took the child from the table, and standing on one foot, with the patient hanging head down on the other leg, did artificial respiration for six or eight minutes before there were any signs of life. Then putting the patient back on the table we prepared to resume the operation. The anesthetizer, who had not moved from his stool, put the mask over the patient's face and resumed the chloroform. I told him to take the mask off and give no more chloroform until he had to. We finished the operation, which required twenty or twenty-five minutes, without another drop of chloroform being given, and during that whole time the child was

as limp as a rag. That anesthetizer afterwards told me that he had not given more than a dozen anesthetics, that he had never received any instruction at all, but had never had any trouble before. A surgeon once told me that he did not care who gave his anesthetics, that he believed they were just as safe in the hands of one person as another. He acknowledged having had a number of deaths from anesthetics. If his opinion is correct, this is the only instance on earth where knowledge and skill are of no advantage in carrying on a complicated process. I believe few surgeons would have the hardihood to make public such an opinion if they held it; yet the majority of them in practice act as if this were their opinion. They are perfectly willing that medical students or recent graduates without any skill or instruction; or, even persons making no pretense to medical knowledge, should administer anesthetics to their patients. In remote districts, where doctors are few, and emergencies are urgent, this is justifiable. In a city like Chicago such emergencies almost never arise. There is another opinion among the profession at large which might be called a superstition; it is that if a patient is taken off the table alive the anesthesia has been entirely successful, even though the patient lies in a stupor for hours afterward. There can scarcely be a greater mistake than this. The patient should have enough anesthetic to allow the operation to proceed without consciousness on his part or interference with the work of the surgeon. The ideal anesthesia would be one in which this was attained with the use of the smallest possible amount of the anesthetic and not one drop more. It is, of course, impossible to attain this condition exactly, but it may be approximated by skillful administration and by continuous, and the closest, attention to the condition of the patient every moment of the time. While in most cases, unless the patient is very feeble, or there has been great shock from the operation, he should revive and become conscious within a very few minutes after the anesthetic is discontinued; but if he has been drowned in the vapor of the anesthetic, he may lie relaxed for an hour or two afterwards; such a condition certainly adds greatly to the gravity of the operation. *Many operations are practically devoid of danger, but no anesthetic is ever administered without jeopardizing the life of the patient.* If a surgeon takes a hundred dollar watch into a jewelry store and asks to have it repaired or cleaned, and the jeweler hands it over to a wholly inexperienced apprentice who ruins it, the surgeon would consider the act of the jeweler unjustifiable. If this same jeweler comes to the surgeon for an operation, he is sent to a hospital, and very likely an inexperienced interne is called upon to administer the anesthetic. Every surgeon realizes that this is the state of affairs which exists; but very few make the slightest effort to remedy it. The responsibility for this condition of things lies not wholly with the surgeons, but partly with those who are in authority in the medical colleges. The subject is scarcely ever mentioned to the students; no effort is made to interest them in the subject of anesthetics, and the facilities at hand are not used, or are inadequately used for purposes of instruction. A few of the students appreciate their responsibilities

when called upon to administer an anesthetic and are anxious for instruction. A few days ago in one of the college clinics, a student was assigned by the man in charge of the clinic to administer an anesthetic to a little girl. I was attending this clinic for the purpose of instructing students in the use of anesthetics, and told this one that I would put the little girl to sleep; that he should watch carefully how it was done; I would then turn the case over to him, and give him what instruction I could. When I had the child anesthetized, I looked around for the student, and he was gone. I saw him in the next room talking and laughing with other students; he was keeping one eye on me, and when he saw me look he hastened in and asked whether I was ready for him. I said to him: "I thought you were going to stay and learn how to give chloroform?" He replied, airily: "Oh, I am not afraid of chloroform; I never have any trouble with it; I have given it twice." I turned the patient over to his care, or carelessness, and left the room, believing that any effort toward instructing him would be wasted. One in every two or three thousand anesthetics result fatally. How many of these might be prevented if all anesthetizers were careful and skillful, it is, of course, impossible to say; but surely many of them. Do you suppose a surgeon would be looking about him and laughing and talking while opening the abdominal cavity, if one in two or three thousand, or one in ten thousand, were accidentally killed by him at the very beginning of that operation? I rather think he would be very seriously intent on his work, and acutely alert to every indication which might enable him to minimize the chances of a fatal result; yet I have often seen an anesthetizer holding an ether cone over the face of a patient, while he was engaged in flippant conversation with some one, and not looking at the patient at all.

The number of times a man has administered anesthetics is no criterion of his skill, though he may acquire skill by practice and without instruction, he will do so at an wholly unknown expense to the unfortunate patients who come under his care. I have resuscitated, or helped to resuscitate, when artificial respiration was necessary, seventeen patients from an overdose of an anesthetic. I have not had a case of my own for nearly six years until within a few weeks. This one case illustrates so well the power of chloroform, as well as the dreadful suddenness of its action, that I shall describe it. The patient was a woman, and the operation was for the removal of a calculus from the common duct. The patient was in a very weakened condition, and the surgeon warned me that he feared trouble from the anesthetic. Chloroform was the anesthetic selected. The patient was anesthetized, placed upon the table, and the operation begun. She had taken the anesthetic without the slightest untoward symptom; all reflexes were abolished; the pupils contracted; ears, cheeks and lips pink; circulation and respiration perfect; but the abdominal muscles were rigid. A little more chloroform was given, and although the patient's condition remained as before, I felt that the anesthesia was as deep as was safe. The surgeon again remarked that the abdominal muscles were unrelaxed; the other conditions remained perfect. I picked up the chlo-

roform bottle with some misgivings. I was using a small piece of gauze bunched over the patient's mouth and nose as an inhaler; I put on *three* drops of chloroform, and before I could set the bottle down the pupils dilated widely and respiration ceased. I instantly removed the inhaler, raised the patient's jaw, inserted my finger in her mouth, and raised the epiglottis. The change was so sudden that I believed respiration would be resumed spontaneously. The color of the patient's face, and the appearance of the eyes soon dispelled that illusion. The operation was suspended, artificial respiration resorted to and continued for about one minute before natural breathing was re-established. The operation was resumed, and, strange enough, though the patient was never again so completely anesthetized (the surgeon insisted on changing to ether), the abdominal muscles were completely relaxed. The anesthesia had been produced so quickly, and the surgeon had worked so rapidly, that a very short time had elapsed from the beginning of the anesthesia to the time of the accident, so that I believe that had the anesthesia been maintained at the same safe degree a little longer time, the abdominal muscles would have relaxed. If unnecessary deaths occur from anesthetics, the responsibility extends beyond the anesthetizer and includes the managers of medical colleges who ignore its importance; who make no effort to teach it properly, if at all, and who confer diplomas which the people accept as evidence of a training which the student has not received.

ESOPHORIA, OR LATENT SQUINT.*

By FRANCIS VALK, M. D.

of New York.

Professor of the Diseases of the Eye, New York Post Graduate School and Hospital, etc., etc.

Ophthalmology, as well as other branches of our profession, has been advancing during the past decade, and to-day the methods of diagnosis and the treatment of the conditions of errors of refraction and the motility of the eye, are almost complete, so much so, that we may and can complete our diagnosis of these conditions simply by the objective examinations. It is to this advance that I would suggest to you the consideration of latent squint. I remember, not so many years ago, at the time I read my first paper on refraction, before this Society, that nearly all my cases were reported as simply hypermetropic and we gave little thought to the muscular equilibrium or balance of the eyes. Hence, many of our cases failed to find the relief from the use of their glasses, as might have been expected. This was no doubt due to the imperfect methods of examinations in use at that time, as now the results would be far different. But all ophthalmologists have not agreed upon the exact methods of examinations that we should pursue, nor are the results of our final work the same in all cases, even though we may be so much more exact in the estimation of the refractive condition of the dioptric apparatus, particularly so in the methods of testing the motility of the eyes, in other words, the power of the eyes to move in

*Read upon the Medical Society of the State of New York, Albany, January, 1901.

the field of fixation and in that of fusion. May I not also suggest that there is the same difference of opinion in the other branches of our profession, of which you are more interested than this one, as I believe it is not fully settled yet whether antitoxin is a true and positive specific for that dreaded disease, diphtheria, and as to the right and proper time to operate in all cases of appendicitis? Some will advance one method, and yet we will find others who will take the opposite side just as strongly. Medicine has not yet reached that stage—nor do I think it ever will—when we can make the conditions of all our cases an exact science, by which we can tell just what will be the final result, as in all we must deal with the personal equation of our patients, an extremely varying quantity. If others may have diverse opinions, so do the ophthalmologists hold the same in reference to the subject I propose to present to you, and while some may tell you that latent squint does not exist, or simply requires the use of glasses; others will tell you that nearly all cases of asthenopia present this condition, and that the majority will require one or more operations.

For my own views, I must say that I am inclined to take a conservative course, simply endeavoring to correct the refractive error, whatever that may be, and then to place the muscular apparatus, if necessary, in that condition of equilibrium that Nature obviously intended it should have. Having done this, and the patient finding no relief, I can justly feel that the eyes are not at fault. My methods of examination may not be correct—as they are not approved of by all—but they have at least the advantage of having been used for many years, and so, as to their reliability, and to the advisability of operations, I must leave to your own conclusions. If not correct, they will not stand the test of time and will soon pass into innocuous desuetude. There is much diversity of opinion in reference to the condition of the muscular equilibrium of the eyes. When there is an absence of this condition, the writers state that the fundamental cause is hypermetropia, and then proceed to explain the relation between cause and effect, or, we may say, the physiological connection between accommodation and convergence, to account for it. But they fail to point out why this condition may and does exist when the refraction of the eye is found to be myopic. So we find this latent tendency, with myopia, described in "vague terms" as ciliary spasm—a rare condition in myopia—or we find no explanation at all; or, again, it is so described that the reader cannot decide what is the chief or primal cause of the symptoms, and is completely at sea as to what procedure he shall adopt when he fails to correct his cases by the use of glasses or by the method of exercising the muscles, so frequently suggested. It is for these reasons that I shall attempt to give some suggestions, based on the treatment of my own cases, which has invariably given relief. At one time I also held the opinion that hyperopia was the cause of this condition, but I noticed the vast number of hyperopes that had no tendency to latent or fixed squint, and that the greater the hypermetropia, the less did I find this inability to keep the visual lines fixed, then I began to doubt my former opinions. When I also found

this condition associated with myopia, and even emmetropia, I felt compelled to discard the theory of the connection between accommodation and convergence as the true cause of the squint, and naturally to look for other reasons that would meet all the indications. This, I think, can be found in the field of fusion or the desire for single vision existing in the human eye. This desire for single vision, or fusion, must be controlled by a different center of the brain than that which controls the movements of the eyes in the field of fixation.

The power of an eye muscle to act according to its physiological function is shown, first, by the ability of the individual to do certain acts by the process of muscular contraction, stimulated by the innervation and controlled by the will power, and secondly, the power to turn the eyes, one independent of the other, under the stimulation of the desire for single or binocular vision. This latter power is the fusion force, and is not under the control of the will power of the individual. Under these conditions, we find that the eyes can turn to all parts of the field of fixation in nearly the same degrees of the arc of a circle, while on the other hand the eye will also move to a certain extent and within a certain field (*fusion*), not by the will power, but by that of the muscular apparatus, under the stimulation of the center for fusion, from the desire for single images, or that the images may be on corresponding parts of the retina. This power of the muscular apparatus seems to be limited within a certain field, and we find this fusion force acting in the same way when the eyes are directed to the different parts of the field of fixation. Hence the ability to fuse these images must be controlled by a special center, and the extent to which the eyes can be turned to produce this fusion must represent the power of the muscles to turn the eyes. I can see no other way to consider the action of the ocular muscles than as their individual power to turn the eyes under certain conditions; moreover, I cannot consider this force as innervation, nor that there should be more stimulation to one muscle than to the other, since the size and the insertion of all the straight muscles seem to point to the fact that one muscle must have more power than the other, or, in other words, exert a greater power to turn the eye under the stimulation of the fusion force.

The physiological act of turning the eyes in all directions within certain limits requires very little force, as is well shown by the action of the interni and the superior recti muscles, for the eyes will turn upward as well as inward; and yet the size and the insertion of the interni clearly indicate that these muscles must have been intended to exert a greater power in some way. May we not also accept the supposition that Nature arranged this muscular force, not only to perform the simple act of turning the eyes, but that they might also conform to all the requirements of the more important functions, namely, that of binocular vision and convergence, as controlled by the fusion force of the eyes? Do not the daily needs of vision confirm all this? It is in the act of single vision, both for the distant and near points, that we find the eyes constantly called upon to keep the visual lines fixed on an object, while at the same time the eyes are moved to different parts

of the field of fixation. Upon this supposition I cannot see what influence innervation, the position of rest, or the natural elasticity of the externi, have to do with the fusion of the images on the retina. If we accept this reasoning, and believe that certain muscles have a greater power to turn the eyes under certain stimulation, then we should have some test, sufficiently reliable and exact, which will meet the requirements, and indicate to us what is the actual power of these muscles to turn the eyes under certain conditions. I have used and tried faithfully all the various tests as suggested for this purpose, such as the phorometer, Maddox rods, etc., but I can find no one so reliable and so clearly indicative of the power of these muscles as the old and simple prism test. We turn the eyes in the field of fixation under the stimulation of the will, simply because we wish to see in certain directions. This is the conscious part of the action of the eye-muscle; but having performed this act, we now call into action the unconscious part, in which the eyes must adjust the visual line according to the direction of the rays of light as they pass through the dioptric media. If these rays of light are deviated from their natural path, the eyes will turn on the center of rotation to meet the deviated rays until the visual line will be parallel with them and the principal axial ray falls upon the macula. If I deviate the rays passing into one eye 20° from a direct line, then to have single vision there must be sufficient muscular power to turn the eye in the direction of the deviated ray, namely 20° of the arc, and if we cannot fuse the images then, we do not have sufficient muscular power in the muscle so tested. Therefore, the strongest prism that will deviate the rays and yet have single vision remain must indicate the power of that muscle to turn the eye. Now if the deviation by a prism represents the power of the eyes to turn on the center of rotation under the stimulation of the fusion force (duction), what do we find is the relative force or power of these straight muscles? Evidently we may have some standard comparison, in the same way and for the same reason, that we have the standard for the acuity of the vision. First, the power of the externi to turn the eyeball outward must be considered. Let me state at once that I do not consider this power as acting from the position of extreme convergence or any point midway between that of extreme convergence and divergence, as has been suggested by some writers, but as starting from the usual first position of the eyes, in which they are directed toward a point about twenty feet distant and about 15° below the horizon. Secondly, the power of the eyes to move under the stimulation of that unconscious force, or duction, as shown by the prism test must be measured. We should find the outward movement or abduction about 6° ; any decided variation from this may indicate some latent squint. The inward movement or adduction is about 24° ; the upward movement or sursumduction, about 2° , and the downward movement, or dorsumduction, about 3° , or somewhat greater than the upward power. These movements are indicated by the relative size and insertion of the straight muscles, and very beautifully represent the power of the muscles to turn the eyes under the desire for single vision, while the slightest failure

of this muscular power may result in diplopia. Now, in the above standard we shall find a certain relation in the power of these muscles, one to the other, as the interni are the most powerful, next, the externi; then the inferior, and lastly the superior, each one having a certain ratio to the other. When this is constant—no matter what the actual power may be—we will not, as a rule, find much, if any, muscular asthenopia or tendency to latent squint. Having then this standard by which to compare the results of our tests of the muscular balance as found in our patients, what will be the indications of the condition that is the title of this paper? At once we note that the power of the interni is far greater than that indicated by our standard; or vice versa, that the power of the externi is too low, so that under the stimulation of the fusion force the power of abduction is not great enough to control the position of the eyes except by the excessive stimulation of the externi to keep the visual lines fixed. These patients present the usual train of symptoms, chiefly pain in the head, radiating backward toward the neck, and a pulling sensation about the eyes. Latent squint of the convergent class is sometimes described as spasmodic action of the interni, and in some cases our tests show this condition; but even if it is spasmodic action of that muscle, it still indicates too much power and should and can be controlled by proper and suitable means. Some of my best cases have shown this condition, as I have noticed a peculiar change in the response of the externi to the prism test, in which there seems to be a decided loss of power after we have tested the adduction. This is shown by our test as well as by the phorometer or the Maddox rod. If we test the power of abduction we find a certain ability to turn the eye outward under the stimulation of the fusion force, that, as measured by the prisms, may be as high as 8° . Now testing the adduction in the same way, we have 20° or more, showing a fairly good balance between adduction and abduction; but if we go back and again test the power of abduction, we will find that it has become reduced to 1° or 2° , or possibly we will have homonymous diplopia—particularly if we place a red glass before one eye, which may persist for some time before the balance again adjusts itself, and we have single vision. I have considered this a very valuable test to develop the tendency of the eyes to turn inward and while it may be due to some spasmodic action of the interni, yet I consider it one of the best indications for the operation I shall propose. Having found the conditions of latent convergent squint, our methods of treatment for its correction are, first, the use of suitable glasses to correct any existing refractive errors; these failing, the combination of prisms with the glasses may be tried; then, possibly, tenotomy of the interni; but best of all, in my opinion, is the operation for shortening the externus with the catgut suture, thereby increasing its power to turn the visual line outward and at the same time avoiding all danger of an over-correction. It is to show the results of this operation of shortening the ocular muscles for the correction of this condition that I present these cases from my private case-book, and also to demonstrate the utility of this standard test:

Case, 1484. Hy. with Ah. glasses for four years, V.-20 20 Ad. 20°, Ab. 2°, (Ratio 1 to 10). Operation shortening Ext. Rect. Result, Ad. 15° Ab. 4°, (Ratio 1 to 4).

Case, 1755. Hy. with Ah. glasses several years, no relief. V.-20 15, Ad. 25°, Ab. 2°; after testing interni, Ab. 0°. Was told by another oculist that operation would do no good. Operation was shortening left externus, result, Ad. 15°, Ab. 5°. Two years later reports: Can use the eyes all that is needed with comfort.

Case, 1829. Ah. glasses, V.-20 15, Ad. 30°, Ab. 4°. Operation, shortening left Ext. Rect. One year after, is so much improved that she returns and asks for an operation on the other eye and I shortening the R. Ext. Rect. in the same way with this final result, Ad. 20°, Ab. 5°. Can now use the eyes with comfort.

Case, 1839. Hy. with Ah. using glasses, no improvement. V.-20 15. Ad. 15°, Ab. 0°. Operation shortening L. Ext. Rect. result, Ad. 16°, Ab. 3°.

Case, 1909. My. with Am. using glasses, V.-20 15. Ad. 20°. Ab. 4°. after testing Interni, Ab. 0°, operation shortening left Ext. Rect. Final result. Ad. 15°, Ab. 6°. Two years later reports no pain or asthenopia.

Case, 1492. Hy. with Ah. using glasses, V.-20 20, Ad. 10°. Ab. 1°, Operation shortening left Ext. Rect. One year after has Ad. 12°, Ab. 4°.

Case 1977. Hy. using glasses, V.-20 15. Ad. 25°, Ab. 0°. Operation, left Ext. Rect. Final result, Ad. 20°, Ab. 6°.

Case, 2051. Ah. using glasses, V.-20 15, Ad. 30°, Ab. 6°. After testing interni, Ab. falls to 0°. Operation on Ext. Rect. Final result, Ad. 20°, Ab. 6°. six months after operation.

Case, 2065. My. using glasses, V.-20 15. Ad. 30°, Ab. 3°. Operation Ext. Rect. Final result, Ad. 24, Ab. 6°.

Case, 2292. Hy. with Ah. using glasses, D.-20 20, O.S.-20 40. Ad. 30°, Ab. 3. Operation, Final result, Ad. 20°, Ab. 6°.

Case, 2371. Hy. with Ah. using glasses, V.-20 20. Ad. 25°, Ab. 6°. after testing interni, Ab. 0°. Operation shortening Rt. Ext. Rect. One year after, Ad. 25°. Ab. 6°, permanent.

Case, 2385. Ah. ax. 180°. using glasses, V.-20 15. Ad. 20°, Ab. 4°. after testing interni, Ab. 0°. Operation shortening. Four months after, Ad. 15°, Ab. 4°.

Case 2088. Ah. using glasses, V.-20 15. better with glasses, but not relieved. Ad. 20°, Ab. 1°. and homonymous diplopia after testing interni. Operation shortening. Ab. 4°. much better.

Case, 2459. Ah. using glasses, V.-20 15. Ad. 25°, Ab. 2°. falls to 0°, with homonymous diplopia after testing interni. Operation shortening. Six months after, Ad. 15°, Ab. 5°.

Case, 2621. Ah. V.-20 15. Glasses do not stop asthenopia. Ad. 20°, Ab. 1°. Operation shortening. Result, Ad. 15°, Ab. 4°.

Case, 2571. Ah. ax. 180°, V.-20 15. Glasses relieve at first, then fail. Ad. 15°, Ab. homonymous diplopia with red glass. Operation shortening, result, Ad. 15°, Ab. 5°, complete relief.

These cases usually present the history that the patients cannot read; the eyes are painful; headaches, frontal and usually extending backward, are experienced; and there are car sickness, nausea, etc., etc. I have presented the histories of these cases of esophoria, or latent convergent squint, in the simplest condensed form possible, noting the refraction; glasses worn without relief; acuity of vision; the muscle imbalance; the muscle operated upon, and the final result. They all seem to show a want of power in the externi recti muscles, a tendency for the eyes to turn inward, and finally show an improvement in that power, by the muscle balance after the operation. Now, I would state that the same operation was performed in each case, namely, that of shortening the muscle by the insertion of the catgut suture with a single needle so as to form a "tuck" at the insertion of the tendon into

the sclera, and allowing the suture to be absorbed. The operation was described in the *PostGraduate Journal* for May, 1896, and it seems to me to more fully meet the indications than any other procedure, such as graduated or partial tenotomy of the interni, since we have a want of power in the externi recti muscles. To counteract this imbalance, I have found the operation for shortening the straight muscles the best in my experience. Some of you must be familiar with this simple method of mine, by which I shorten the ocular muscles in their long axis, thereby increasing its natural power to turn the eyeball under the stimulation of single binocular vision, but in a few words I would state that I use a single, sterilized catgut suture, and after the muscle has been exposed, dissected from its sheath in Tenon's capsule and held away from the eyeball by these little twin strabismus hooks, the needle is passed through the tendon very close to the sclerotic, then under the muscle and as far backward as we propose to make the "tuck," and then through the belly of the muscle. Now crossing the muscle with the suture, the needle is again passed through and under the tendon, at a point above or below the place at which we started. You can now see that as we tie the suture over the insertion of the tendon, we must bring the middle part of the muscle forward, so taking the "tuck," and shortening the muscle very materially in its long axis. There is very little if any reaction after the insertion of this suture; it does not require a second operation for its removal, and the prominence remaining gradually flattens out and disappears in from six to eight weeks. The operation has never failed in my hands, and I am glad to say that in the hands of my friends it has shown the same measure of success and may be used in cases of true squint, of both the convergent and other varieties, as in that of the subject of this paper. In closing, let me say I am trying to follow Nature in the movements of the eye, and to quote from Prof. Tyndale, "In dealing with Nature, the mind must be on the alert to seize all her conditions; otherwise we soon learn that our thoughts are not in accord with her facts."

STRANGULATED HERNIA.

By WALTER LATHROP, M. D.

of Hazleton, Pa

Superintendent and Surgeon, State Hospital, Hazleton, Pa.

The great importance of this subject, and the comparatively frequent occurrence of the trouble, are my chief reasons for bringing it before you this evening.

These cases, as a rule, first come under the care of the general practitioner, and on his judgment and skill much of the result of the case depends, for very often the preliminary treatment, or handling, of the hernia, determines the result, as regards reduction, and certainly the life of the gut, to say nothing of the mortality.

I shall say nothing about the anatomy of hernia, but will speak of the subject in a general way. The clinical varieties leading up to strangulation are the irreducible, incarcerated, inflamed, and, lastly, strangulated. In the irreducible form, we have the circulation and function of the bowel or omentum,

unimpaired, but the contents of the sac cannot be returned or reduced.

This condition occurs often in umbilical hernia, but may be present in any variety. The contents of the sac are usually omentum, though a coil of intestine may also be present.

The symptoms are few in these cases, being usually shown by colicky pains and constipation. Often rest alone will cause the symptoms to disappear, and the hernia may be returned easily.

Local inflammation calls for antiphlogistic treatment, cold applications, and absolute rest.

An incarcerated hernia is an irreducible one, in which the contents of the bowel are held back, or obstructed, and yet the circulation is unimpaired. The symptoms develop slowly, owing to the slow accumulation of feces in the loop of gut, and the gradual filling up of same; constipation is present, and usually a sense of weight, and dragging is experienced. There may be nausea, and even vomiting, but it is not the rule, except in late stages of the trouble. There is pain, often radiating about the abdomen. Examination reveals a tumor quite tense and painful. There is impulse on coughing, but not marked. The symptoms may subside gradually, or increase, and go on to strangulation.

Failure to obtain relief after giving enemas and using all medical means, would lead one to suspect strangulation. In these cases it is positively injurious to resort to force in attempting reduction, and by this I mean the use of taxis, of which I will speak later on. High enemas may be given, and if any result follows, should be repeated, and purgatives given also; rest is imperative; applications to the hernia are essential and useful. These may be hot or cold, but better hot. The salines in small and repeated doses may be used, *after* the enemas have partially reduced the swelling.

If these means fail, then operation is indicated. Inflamed hernia would most naturally occur in an irreducible hernia, where there has been any prolonged irritation, such as taxis (repeated and severe), a blow or fall, an ill-fitting truss, etc. We have in these cases a serous exudation, and a peritonitis, in which the sac and its contents are involved. These cases may be quite severe when the tumor is an entero-epiplocele, but otherwise they tend to recovery. Ice may be used in these cases, and opium may be given if pain is severe; enemas should be used also. No cathartic, or laxatives should be given until pains and tenderness have subsided.

We now come to the most important condition of all, namely, strangulated hernia, which to my mind is one of the most satisfactory of all surgical affections, if attended to at the proper time, and a most unsatisfactory and dangerous one if neglected, or its seriousness overlooked.

Strangulation in a hernia is present when, in addition to being incarcerated, the blood supply is cut off. It is apt to occur in middle and old age, and usually in an old hernia, for which a truss has been worn, often for years; but I have had one case in which the strangulation was apparently spontaneous with the rupture: The man was working in the mines, and on attempting to lift a large piece of coal felt something "give way," as he expressed it, and

from a short time after that till his admission to the hospital (24 hours later), he presented the typical symptoms of strangulation, and the operation proved it to be so.

The chief causes of this trouble are: straining, lifting, vomiting, sometimes coughing, absence of truss, after wearing for a time, or any severe muscular action. It may also follow in irreducible or incarcerated hernia, after manipulation has been prolonged. It is said to occur oftener in femoral than in inguinal hernia, though I have not yet seen one of the femoral variety.

As to the mechanism of strangulation, many theories have been advanced, and it is probable that there is some truth in all of them; suffice to say, that venous congestion, and interference with the blood supply is a chief factor.

We have the compression of the ring itself; we have frequently fecal impaction, and paralysis of the muscular coat of the gut. Congestion is increased, serous exudate thrown out, and thus the volume beyond the neck is increased, and reduction rendered impossible. The pathology of this condition is well described by Coley. The seat of most marked pathological changes is, in most cases, at the neck of the sac, not because the neck is an active agent of constriction, but on account of its being the narrowest portion of the sac, and the tissues being densest, and most resisting immediately about it. In some instances the lesions may be most marked in the sac, owing to its own constricting effect. The first abnormal phenomena are those of venous obstruction. The color of the intestine becomes dark red, blue, or mahogany. The wall is thickened from edema, and its surface becomes dull, instead of glistening. This is followed by exudation into the sac, the fluid being first clear, then bloody or turbid. This is followed by coldness of the bowel, a deep furrow at the neck, becoming later on gray or yellowish in color, but first hemorrhagic. The whole loop may become gangrenous, and separation of the slough may occur at the neck, the sac being converted into an abscess cavity. There may be lesions of general suppurative peritonitis before this occurs, or local peritonitis and adhesions about the neck, may prevent infection of the general peritoneal cavity.

Symptoms.—These are, as a rule, well marked, and should not be overlooked in making a diagnosis, between strangulation and simple irreducible hernia, though the latter may become strangulated if not relieved. The general symptoms are those of intestinal obstruction. The local are usually pain, tenderness on pressure, irreducibility, and loss of impulse.

Where the hernia has been reducible, the symptoms are shown after straining at stool, or a sudden effort, such as a heavy lift, vomiting, or violent coughing will sometimes produce it.

The pain is often referred to the umbilicus, or to neck of the tumor. There is no impulse on coughing, and a dull sound on percussion. The general symptoms are usually well defined; there is nausea, vomiting and severe pain. The vomit changes in character from the contents of stomach to watery substances, bile, and later on to fecal matter. Constipation is absolute, the only movement of bowels

being below the seat of trouble, which might follow the use of enemas. The temperature is not elevated, as a rule, but the pulse is increased, slightly at first, and soon becomes rapid, as the trouble progresses. Nourishment is refused, from the fact of persistent vomiting. The prostration becomes greater and the countenance assumes an anxious look. The abdomen may be swollen, and tympanitic. The extremities grow cold, cyanosis is present; and then hiccough occurs, and dissolution is the outcome, after a period of from four to eight days. *This is a case in which operation is not performed.* The diagnosis would be shown by the symptoms of intestinal obstruction, vomiting, constipation, and pain with a tumor at the site of the hernia.

The prognosis depends on the length of time the strangulation has progressed. The mortality is greater, the longer the time of operation is delayed.

The complications may be several, such as peritonitis from sloughing of returned gut, and consequent infection. Local peritonitis may be present for a time, but is not serious; shock may cause death in old patients, and in late operations.

It is said that the mortality is from 10% to 12% in cases operated upon within 36 hours, or less, while 50% die after delaying three days. It is said to be greater in umbilical hernias, than in femoral, or inguinal.

Treatment.—We have two things before us in these cases: first, to return the contents of the sac to the abdomen by what is known as taxis, and second, to do the operation of herniotomy. It is wise before doing either of these things to try the effect of rest, opiates (hypodermically), and cold applications to the tumor. In very large hernias, or in old persons, hot applications are best; always keep the thighs flexed, and pelvis elevated.

These procedures being unavailing, the next thing is to try reduction by taxis; and right here let me state that after a fair experience with these cases (40), I believe taxis is decidedly *harmful*, and personally, I am opposed to trying it. If used at all, it should not be longer than *three to five minutes*. It is all right to try in *emergencies*, or when operation is refused, or some time must elapse before surgical aid can be procured. Again, some diseases may contraindicate operation, such as serious kidney lesions, but even in these cases local anesthesia can be used, and the strangulation relieved, thus rendering prolonged manipulation or taxis entirely unnecessary. Some of the dangers of taxis are, if too severe, or prolonged, rupture of bowel or production of subsequent peritonitis. There may result an apparent reduction, yet the symptoms reappear after a few hours, owing to the sac being reduced, and yet the constriction at its neck not being relieved. Aspiration of the fluid in the sac has been recommended, but is of little value.

If reduction should follow taxis, the after treatment should be rest in bed, until the bowels move, replacement of truss if opening be small, and *best of all*, the radical treatment of the case. It is not necessary to remind you of the contra-indications to performing taxis, but in general it should never be attempted *after twenty-four (24) hours*.

The next consideration is relief by operation. I believe the mortality recorded against operations for strangulated hernia is due largely to *injudicious*

and *prolonged taxis*, and postponement of operation till late stages of strangulation.

If performed *early*, I believe the operation of herniotomy to be practically safe, and the result almost certain.

Under anesthesia, a free incision should be made down to the sac, then proceeding carefully, the sac is opened, and the constriction sought for and then divided. The bowel should now be inspected, and will be found in nearly every case to be dark and hemorrhagic, and frequently will require some thinking to determine its vitality; hot saline solution should be used freely and warm gauze sponges applied to the intestine. Returning circulation will be shown after a few minutes, by the change of color, from dark brown to reddish, and then to a fairly healthy look, though congested.

It may now be replaced, and a radical cure be performed if the patient's condition warrants it, and I have not yet failed to do the complete operation. Cushing, of Johns Hopkins, advocates the use of local anesthesia in these cases, and has reported a number of operations. He uses infiltration anesthesia, and has had good success. It is certainly adapted to aged patients, and those in whom serious kidney complications are to be feared. Several New York surgeons also use eucaine B. in some of their cases; I have had no experience with eucaine, but mean to try it as soon as I have the opportunity; but believe I shall prefer general anesthesia. I had recently an interesting case of strangulated inguinal hernia in a woman, five months pregnant. The tumor was large and hard. The operation was performed one hour after her admission, and showed a large enterocele, the ring of constriction being exceedingly tight, and the mass of intestine large, and very suspicious in appearance. The constriction was relieved, the intestine covered with gauze wet with saline solution, and after a few minutes the color improved, and I returned it to the abdomen, ligated the sac, and did a radical operation. Her recovery was rapid and uneventful.

In February I had another case of interest, this, also, in a woman pregnant, and presenting a large strangulated umbilical hernia. She had been ill four days, was vomiting continuously, and had absolute obstruction of bowels. Taxis had been practised until the surface of the tumor looked like a large inflamed area over an abscess. Her condition was anything but favorable, but I determined to operate at once, and had her prepared rapidly, and etherized. A free incision showed a mass of omentum, in the centre of which was a large knuckle of gut, very dark and forbidding in appearance. I found a very tight ring of constriction, which was divided, and the usual treatment of the bowel begun. After probably eight or ten minutes the color began to improve, though very slowly, several large hemorrhagic spots persisting, leading me to fear perforation; but I determined to replace the bowel, and trust to nature, as the woman was in a very critical condition. I closed the opening completely, with three rows of chromicized gut, and to be brief, her recovery was uneventful, and she went home in twenty (20) days, none the worse for her very narrow escape.

I have little to add to this article, but I would like

to impress the importance of early interference in these cases, and my belief in the safety of operation when taken in time, and even when gotten late, we should not despair, but resect the gut if gangrenous, though careful applications of hot saline should be thoroughly tried beforehand. I believe a radical cure should be done in every case where possible, and there is practically no added danger in doing it. To sum up then, I would say:

- 1.—The mortality in these cases is due to delay in operation, and to unnecessary taxis.
- 2.—Taxis is never free from danger, and its use should be discouraged, save in emergencies.
- 3.—Strangulated hernia is invariably fatal, unless relieved, and early operation will nearly always succeed, and life will be saved.

AMMONIUM PERSULPHATE SOLUTION. A NEW DECOLORIZING FLUID FOR STAINING SPORES AND SPUTUM.

By ROBT. L. PITFIELD, M. D.

of Philadelphia.

Assistant Lecturer in Diseases of the Mouth and Throat.

The following method of staining spores is introduced as new because of the original formula for a new decoloring agent which is used in the process. The decolorizing of anything by acids means oxidization. This method of decolorization depends also upon oxidization. The active ingredient of the reagent is the persulphate of ammonium. This salt of ammonium decomposes in the presence of water and oxygen is evolved. To demonstrate spores, prepare a cover slip as usual, spreading it very lightly, fix in flame and then stain with boiling carbol-fuchsin or Ehrlich's aniline water, gentian violet or fuchsin. The cover slip should be in boiling stain for at least a minute. Wash and run on the following:

Ammonium Persulphate	5 grams
Alcohol, 95 per cent.	50 c.c.
Water.	10 c.c.

At the end of a half minute wash in water and counter stain. The preparation will show red or violet spores and bacilli stained with contrast stain. In case the spores are not stained repeat the staining and decolorize for a shorter period and then counter stain.

The decolorizing solution will keep for several months. After making it, it will be observed that some of the ammonium persulphate is not dissolved. This is unimportant and keeps the solution charged with oxygen for several days as it slowly decomposes.

This solution is slightly acid, but its properties do not depend upon the reaction. The addition of soda, potash, or ammonia to neutralization does not detract from its decolorizing powers.

This stain will decolorize all of the basic dyes in solution. It apparently does not affect eosin, methyl-green or their tinctorial properties. Glycerine causes an amorphous precipitate and destroys the action of the reagent. Sputum may be stained in this way, but there are disadvantages. The stain can decolorize the tubercle bacillus if pushed too far.

The tubercle bacillus resists the decolorizing action of this reagent, and the preparation is clean and free from all precipitates. But the reagent must be kept a day before using, since a fine crystalline deposit forms on the preparation after using a fresh solution.

Histological Study of the Cerebrospinal Fluid in the Course of Herpes Zoster.—BRISSAUD and SICARD. (*Gaz. Heb. de Med. et de Chir.*, March 21, 1901, 48, pp. 400-402, No. 12). At a meeting of the Société Médicale des Hôpitaux, held March 15, 1901, Brissaud and Sicard reported the results of the histological study of the cerebrospinal fluid from 2 patients suffering from herpes zoster. The eruption had a longitudinal distribution. Lymphocytes were present in large numbers. The cells took the stain in a variable way, and were associated in pairs and in chains; more rarely they were actually attached to each other. These cases show that leukocytes may appear in the cerebrospinal fluid, even in such a benign disease as herpes zoster, in which the meninges are only slightly affected. It is probable that lumbar puncture will in the future permit a study, in this disease which is so rapidly curable, of the final disposition of the leukocytes in the cerebrospinal fluid. In the discussion that followed the reading of the paper Vidal said that the interesting studies showed the importance of histological study of the cerebrospinal fluid in the course of nervous diseases. In chronic meningeal processes, such as follow general paralysis, tabes or meningo-myelitis, large mononuclear leukocytes are found as well as lymphocytes. It is difficult in such a case to say whether these large mononuclear cells are leukocytes or endothelial cells. Ch. Achard and M. Loeper said that they had made lumbar puncture in 2 cases of herpes zoster of the lumbocentral region. Cultures from the cerebrospinal fluid in these 2 cases resulted in the growth of micro-organisms that presented the characteristics of certain varieties of the bacillus coli communis, with this peculiarity that inoculated milk was not coagulated at the temperature of the incubator, but became coagulated by boiling. The result seems to add evidence to the opinion that herpes zoster is of an infectious origin. It also confirms the theory that accounts for the cutaneous eruption in a large number of cases by making it dependent upon a spinal or meningeal change that involves either the nerve roots or the nerve centers themselves. Finally, the question arises whether herpes zoster may not be produced by different micro-organisms and whether cerebrospinal meningitis may not be set up by different infections? [J. M. S.]

Recurrent Gastric Ulcer.—Professor Hayem, in *L'Indicateur Médical* (April 1, 1901, No. 14), reports the case of a man of 41, in whom gastric troubles had existed for five years. At first there were symptoms of dyspepsia, then suddenly hematemesis occurred. With treatment he improved. Then the symptoms recurred, again improving with treatment. This was repeated once more. Now he has his fourth attack. There is pain under the xiphoid cartilage, with fecal masses palpable in the intestines, to account for the constipation. He is thin, very pale, and functional murmurs are audible. Hematemesis persists. Hayem diagnosed recurring gastric ulcer. The cause of recurrent gastric ulcer with hemorrhage is unknown. In a case of this sort, it is always possible for cancer to develop, and hemorrhage or perforation may cause death at any time. The stomach must be kept at rest long enough to allow the ulcer to heal well, only small amounts of water being given by mouth, and alimentation per rectum. Should abundant hematemesis occur, gastro-enterostomy may be necessary. [M. O.]

A Rare Idiosyncrasy Toward Quinine.—Gorbatsheff reported before the Moscow Therapeutic Society (*Medicinskoje Obozreniye*, March, 1901), a case of a man in whom even small doses of quinine produced chills, considerable elevation of temperature, delirium, dryness in the throat, thirst, vomiting and a severe dermatitis accompanied by a scarlatiniform eruption. [A. R.]

1.—Out of 22,181 patients received at the First Reserve Hospital in Manila, from August 1st, 1898, to May 1st, 1900, only 7 per cent. had gunshot wounds. There were 59 cases of intentional self-inflicted gunshot wounds, a number of these being wounds of the forefinger. At one time there seemed to threaten an epidemic of these wounds. Of the total number of gunshot injuries received 223 were brought in dead, or died within 24 hours, leaving the total number treated as 1373. The mortality of this latter number was 4.2 per cent. Robinson found the "explosive effect" to be rare, occurring in only 24 cases out of 462. When it did occur it was usually in gunshot wounds of the long bones or of the calvarium. In no instance was it noted in muscles alone, and in but 2 instances was it observed in wounds of solid organs. The old Remington bullet produces a wound which is nearly always infected, and the same is true of the "soft-nosed," or Dumdum Mauser bullet. The modern high-velocity projectile produces a wound which is seldom infected. This is due to its hardness and smoothness, which produces little bruising of the tissues, and to the fact that probably its high velocity produces sterility. Also the early application of antiseptic dressing on the field must be considered one of the greatest means of preventing infection from gunshot injuries in modern warfare. Many of the gunshot wounds of bone, even where comminution takes place, if produced by the modern bullet, will heal without suppuration or necrosis. In a number of cases where the bullet has not been extracted it has produced little trouble. It is thought advisable, however, always to remove the bullet of a Remington or a revolver. In 63 cases of high-velocity gunshot wounds of long bones there were but 12 infected, while out of 27 Remington wounds of the bones 23 were infected. Almost 50 per cent of the low-velocity gunshot wounds of the chest became infected, while only 12 per cent. of those due to the new modern projectile gave serious trouble. Primary hemorrhage from gunshot wounds produced by the modern bullet was very uncommon. Three cases of aneurism are recorded as a result of gunshot wounds. Gunshot wounds of the knee joint are usually aseptic, but if infected, Robinson thinks demand immediate amputation to save life. As the direct result of gunshot wounds there were only 12 major amputations performed, and only 3 of these were primary. A number of interesting cases are recorded of injuries to bones requiring resection: also several cases of interesting gunshot wounds of the face. Three cases are recorded of severe penetrating gunshot wounds of the brain which recovered. Every case but one of gunshot wounds of the spinal cord died of cerebrospinal meningitis in from 3 to

5 days. Robinson is strongly of the opinion that gunshot wounds of the abdomen, when produced with a modern high-velocity projectile, should not be operated upon. Of 30 cases treated without operation 20 recovered. Of 4 cases operated upon 3 died and only 1 recovered. Death from hemorrhage usually followed gunshot wounds of the spleen. Among these patients there were 2 factors which Robinson thinks militated against aseptic surgery, the greater tendency here to infection and the general poor health of the patient. [J. H. G.]

2.—Knott gives his conclusions from a study of 118 cases of sarcoma of the uterus, which he has collected from the literature of the past ten years. Of the 118 cases, 33 were reported as affecting the mucosa of the fundus uteri. Forty-six cases of sarcoma of the parenchyma were found. Circumscribed sarcoma of the muscular wall of the uterus microscopically closely resembles a fibro-myoma. Knott reports an interesting case of diffuse sarcoma of the uterine wall which he considers an extremely rare condition. Sarcoma of the grape-like variety was found in 29 of the 118 cases. These growths usually arise from the mucous membrane of the cervical canal. Sarcoma beginning in the chorionic villi is the most malignant type of uterine sarcoma, and pulmonary metastasis is frequent. Out of the 118 cases there were 10 of sarcoma deciduo-cellulare. The ages of the patients ranged all the way from 7 months to 67 years. As sarcoma of the mucous membrane so closely resembles a simple polypus, microscopic examination of all such growths becomes of very great importance. The most frequent form of metastasis in the cases collected was pulmonary. The only thing which promises anything in the way of treatment in uterine sarcoma is an early and complete hysterectomy. [J. H. G.]

3.—Cystic degeneration of the kidney in adults is rare, occurring more frequently in the male. In most instances both kidneys are involved, one usually being much in advance of the other. The disease may last for a long time without producing any trouble and not become known until the tumor is large enough to be palpated. Albumin is not found in the urine until late in the disease. The condition may be suspected in the presence of a renal tumor with a sudden uremia or anuria in a patient who has heretofore shown no signs of renal disease. The presence of tumor on both sides renders the diagnosis much more likely. The difficulty in treatment arises from the inadequate knowledge of the exact condition of the less diseased kidney, and this can only be told by exploratory incision and inspection. Beck reports a case of a woman 55 years of age who gave an interesting family history, two sisters having died of cystic degeneration of both kidneys. The patient had a tumor in the left abdomen which reached from the iliac crest to the costal arch, and which was nodular and movable. A diagnosis of cystic kidney was made. In operating, the trans-peritoneal route was chosen in order to give an opportunity for examining the right kidney. This kidney was found slightly enlarged and gave evidence of the presence of cysts at its lower pole only. The left kidney was removed in its entirety; it weighed three (3) pounds and was made up of a number of cysts varying in size, the largest being three inches in diameter. The patient reacted well from the operation, and in the first 24 hours passed 17 ounces of urine. Eight days after the operation the urine became scant and renal cells were increased. Uremia set in and the patient died on the 11th day from interstitial nephritis. Beck doubts the advisability of removing a cystic kidney even when the other organ appears to be normal. He thinks that probably a better treatment would be puncture followed by an injection of a drop of a saturated solution of iodoform in ether, for the smaller cysts, and in the larger ones he advised their excision. [J. H. G.]

4.—Curtis reports a case of a girl 20 years of age suffer-

ing from cicatricial contraction of the pharynx and posterior naris following ulceration due to inherited syphilis. The opening from the mouth to the nose was less than $\frac{1}{2}$ inch in diameter. The opening downwards into the esophagus and larynx was only $\frac{1}{4}$ inch in diameter. Her diet was restricted to fluids and semi-solids. Breathing was noisy and difficult, and dyspnea came on with slight exertion. Chloroform was administered, tracheotomy performed and the anesthesia kept up through the tracheotomy tube. The patient's head was drawn over the end of the table and allowed to hang down. A transverse incision was made above the hyoid bone on the left side and deepened until the pharynx was opened between the epiglottis and the tongue. The lower pharynx was found shut off from the upper by a membranous septum extending from the posterior pillar of the fauces and left side of the pharynx across to the base of the tongue. The right side was nearly free from cicatricial tissue and the opening was on that side. The septum was divided with the knife while the finger made pressure from the wound below. The division was continued until three fingers could be passed through into the mouth. A flap of skin was then cut from the left side of the neck near the angle of the jaw and was carried in and sutured over the raw surface in the pharynx, its base being still attached. The upper pharynx was then packed with gauze so as to firmly press the flap into position. Rectal feeding was kept up for 7 days. No infection occurred. The flap healed nicely in its new position. After the first week she was fed through a stomach tube. On the 10th day, under local anesthesia, the skin flap was divided transversely where it joined the mucous membrane of the pharynx. On the 14th day the patient was out of bed. Twenty-four days after the first operation chloroform was again administered and the opening in the pharynx closed by suture. The wound healed rapidly. The tracheotomy tube was removed several days after this operation. The patient was given a soft rubber rectal bougie, No. 4, about $\frac{3}{4}$ inch in diameter, and instructed to pass it at frequent intervals. In spite of the fact that the patient did not do this there has been very little contraction, and the instrument passed with but little difficulty. The transplanted skin in the pharynx has assumed the appearance of mucous membrane. [J. H. G.]

5.—Macdonald thinks that lymphatic involvement in carcinoma of the stomach comes on later than in other organs, and that when the disease is situated at the pylorus the patient is apt to die from stenosis before any very extensive lymphatic involvement occurs. These facts would tend to make a prognosis of pylorotomy more favorable than is generally supposed. Of course the earlier the operation is done the more favorable will be the prognosis, and Macdonald thinks that many cases may be operated upon earlier than is now the custom. He thinks a combination of the following symptoms may be taken as an indication for an exploratory operation: First, a chronic gastritis progressive in spite of proper dietetic medicinal and physical treatment; second, a loss of gastric motility; third, progressive diminution of gastric peristalsis; fourth, a diminution of free hydrochloric acid, progressive in character; fifth, emaciation of patient under forced diet; sixth, reduction of the hemoglobin in the blood progressive to 65 per cent. or under, and a moderate leukocytosis. Hematemesis, lactic acid, the Oppler-Boas bacillus, and epigastric tumor are symptoms which occur too late to permit of radical surgical intervention. When the cardia is involved the esophagus is much more apt to become infected than is the duodenum when the pylorus is the seat of the cancer. In a complete pylorotomy it is very desirable to remove the lymphatics along both curvatures of the stomach as well as those lying behind the pylorus. The line of excision should be at least three centimetres from the line of palpable infiltration. Macdonald thinks Kocher's recent clamps to be the best adapted for this work. It is his custom to close the stomach and duodenum after doing the resection then to anastomose the jejunum with the posterior gastric wall and then to unite the duodenum and jejunum below. During the past year he has employed this method 8 times with 7 recoveries. In making the anastomosis between the stomach and bowel he uses the suture, but in making the anastomosis between the jejunum and duodenum a Murphy button is employed. When a case of carcinoma of the stomach is too far advanced to permit of a radical operation Macdonald has found an amelioration of symptoms to follow a gastroenterostomy. [J. H. G.]

6.—Wharton reports first a case of compound dislocation and fracture of the lower end of the tibia with fracture of the fibula in which a good result was obtained after the immediate resection of a portion of the tibia and astragalus. The next case is one of a compound comminuted fracture of the tibia and fibula in which a loose fragment of the tibia was wired between the distal and the proximal portions of the bone. The patient made a good recovery. His next case was one of fracture of the fibula with marked displacement due to a portion of muscle lying between the fragments. His fourth case was one of Pott's fracture where reduction was only accomplished after a division of the tendo-Achilles. His fifth case was one of comminuted fracture of the upper extremity of the humerus in which an excellent result was obtained from an excision of the shoulder joint. His last case was one of extensive gunshot injury of the shoulder joint in which excision was done with a good result. [J. H. G.]

7.—O'Hara describes an original forceps for making intestinal and visceral anastomoses and illustrates his article by a number of photographs showing the use of the forceps. The instrument is a small one and possesses the advantage of requiring no additional instrument or even the hands of an assistant to prevent contamination of the wound surfaces with fecal matter during the anastomosis. [J. H. G.]

8.—Spellissy describes an improved brace for head extension which is applicable to all cases of Pott's disease in the cervical and upper dorsal regions. He also presents photographs and describes a hard rubber spring brace for lateral curvature. [J. H. G.]

3. The Influence of Bile on Metabolism. ELLIOTT P. JOSLIN.
4. The Relation of Diabetes Mellitus to Lesions of the Pancreas. Hyaline Degenerations of the Islands of Langerhans. EUGENE L. OPIE.

1.—Ewing begins his study of the malarial microorganism by a consideration of the staining methods employed to demonstrate it. He then considers the general morphology of the parasites. He believes that the rings form of the tertian parasite does not represent a vesicular nucleus. The study of this form by Nocht's method indicates that the nucleus of this protozoon is one of the distributed type which does not exhibit a vesicular nor possess a nuclear membrane. The ring form of the tertian parasite may be fully distinguished from the ring form of the estivo-autumnal parasite even in early stages by the following characteristics: (1) The nuclear body and the chromatin mass of the young tertian parasite is achromatic to methylene blue, which densely stains the nucleus of the estivo-autumnal organism. (2) The tertian ring is usually coarse and irregular, but the estivo-autumnal ring is geometrically circular and more delicate. (3) One or two grains of pigment are nearly always invariably found in the early tertian ring but are absent from the estivo-autumnal ring. (4) The tertian ring is usually pigmented before the chromatin becomes subdivided, while the chromatin of the estivo-autumnal ring is always subdivided before the appearance of pigment. (5) The infected cell is usually swollen from the moment of infection by the tertian spore and commonly shrunken when harboring the estivo-autumnal ring. The author interprets the larger forms of the tertian ring which are devoid of chromatin as sterile forms, and cannot accept the view that the chromatin entirely disappears at any stage of the fertile parasite. In specimens stained by methylene blue, the first demonstrable indications of the division of the parasite are seen in deeper staining capacity and tendency toward reticulation. After considering the arguments for and against plurality of species in the estivo-autumnal group of parasites, the author concludes that the evidence secured fails to establish any clinical or morphologic grounds on which to separate the parasites of pernicious malarial fever into 2 or more groups, and he further considers that the grounds are insufficient to warrant the classification of *Hemameba*

immaculata as a separate species of parasite. Furthermore, the arguments so far advanced seem, at best, merely to justify the opinion of other observers that pigment-free rosettes, as seen in the human subject, are an occasional form of the estivo-autumnal parasite. He finds that the nucleus of the malarial parasite belongs to the "distributed type" of protozoan nucleus, consisting of granules of chromatin, and, certainly in the older and possibly in all stages, of an achromatic substance in which the granules are imbedded. While the claim of Bastianelli and Bignami that the parasite possesses no "true nucleus," in the meta-zoan sense must be admitted, it exhibits, nevertheless, all the nuclear structures required in some protozoa. In specimens derived from fresh malarial blood, chromatin was never seen in the form of a filament, all elongated masses being invariably of granular structure. On the other hand, when exflagellation occurs with the human parasite, the chromatin becomes filamentous, figures representing monaster are produced and the chromasomes are extended as active flagella. It appears, therefore, that in the further cycle of the malarial parasite, division occurs by a very simple process which may be likened to amitosis, the only visible changes in the chromatin being subdivision and fusion. In another cycle of development, adapted for the extracorporeal growth of the parasite, division occurs by a modified form of karyokinesis, the chromasomes leaving the parent cell to fertilize other individuals. The full significance of crescentic bodies, even in the coccidia, has not yet been demonstrated, although the position of these bodies in the development cycle has been determined. There is evidence in the coccidia that some of the crescentic bodies represent the female element and require fecundation by the flagellum or male element in order to become fertile. Of the mode of origin of the crescents in man there is still nothing definitely known. With Nocht's method, however, the author has been able to demonstrate chromatin granules in the vast majority of crescents in all stages. That the young parasite during its passage from the parent rosette to the new red cell is sometimes caught in the plasma in both fresh and dry specimens is evident from the reports of various observers. The possibility of identifying such young forms in the fresh condition may, however, be doubted. The young parasites probably swim in the plasma for a very short time, and soon become attached to red cells. They remain attached to the cell for a while, but soon penetrate within, where their further development is completed, as has already been explained by Mannaberg. In 4 cases of tertian infection the author has encountered appearances in the blood that seem to admit of no other explanation than that of conjugation of malarial parasites has been accepted probably by a majority of clinical observers residing in temperate climates; but seems never to have gained uniform support from those who have studied largely in tropical climates, nor from comparative biologists. The strongest evidence in favor of plurality of species is found in the results of experiments on the inoculation of malaria, which, when properly controlled, have invariably produced the type of organism found in the specimen of blood used in the inoculation. Whatever may be the final outcome of the discussion it cannot be doubted that the 3 groups of parasites, quartan, tertian and estivo-autumnal, exhibited morphologic characters that are to a large extent immutable. Yet the 2 widely different forms—the estivo-autumnal rings and the crescents—are regarded as belonging to the same species, and the whole ground-work of a morphologic classification is found to be insecure on account of an extreme polymorphism observed throughout the entire group of protozoa. [J. M. S.]

2.—After tracing the fibers of the chorda tympani nerve in the submaxillary gland, Sihler came to the conclusion that the gland cells themselves are not supplied with nerve fibers, but that the terminal fibers are found on the capillary vessels just as in the case of the capillaries of muscular tissue, and that, therefore, those nerves of muscle that are analogous to the glandular nerves are not the motor nerves proper, but are those going to the capillaries. The author's histologic studies lead him to the conclusion that there is a vast peripheral network of fine nerves, co-extensive with the capillaries of the muscles and glands, which has connection with sensory nerves and into which motor nerve trunks also enter, and which he therefore looks upon as being both sensory and motor. These nerves,

so intimately connected with the capillaries, influence the protoplasm of their walls in such a way, that, according to the activity of the nerves, the transudation of lymph is increased or diminished. Further, they take cognizance of disturbances of a local or mechanical nature, and, in response to local causes of irritation, influence the capillaries of a part to pour out more fluid and act in the interest of the organ in question. As increase of lymph formation and vasodilation must, in the long run, go hand in hand, it would seem reasonable to suppose that the nerve fibers going from the capillaries to the arteries and veins may exert an inhibitory influence on the vaso-constrictors, or a stimulating one on the vasodilators, thereby a larger supply of blood is furnished to the irritated part. The author's investigations have led him to conclude that the motor nerve-endings of the muscles remain on the outside of the sarcolemma, and except that the surfaces where muscle and nerve come into contact are covered with a strong sheath of Schwann which has its own nuclei. What may be the exact condition of things at the points where muscle and nerve fibers are in actual contact whether the sarcolemma and neurolemma are wanting there, or perforations exist, or whether electrical phenomena observed in nervous activity can be used to explain the processes going on there—cannot at present be stated. The precise relation of muscle to nerve here is an unsolved and difficult histologic problem. [J. M. S.]

3.—In the case of a married woman, aged 54 years, who for the past 3 years had suffered from attacks of gall stone, operation was undertaken for the relief of the condition. The patient's condition became so critical while on the operating table that the gall bladder alone was emptied of stones and a biliary fistula made, the duct being left untouched. After the operation the discharge of bile from the wound was constant, the stools remained colorless and repeated tests failed to show bile acids in them. Joslin then instituted a series of experiments to determine the influence of bile on metabolism. The experiments were divided into 3 periods which were similar in all respects except that in the middle period the patient received 30 grams of dried ox bile daily. As a result of his experiments the author concludes: (1) That bile increases the digestion of fat when given by the mouth in pill form. The percentage of fat lost in the stools of the patient with complete biliary fistula was 63% in the first period and 57% in the third. Under bile medication the stools contained 23% less fat than in the first period and 17% less than in the third. In other words, bile increased the digestion of fat relatively by 50%. (2) That the digestion of nitrogenous food is improved by bile pills, when the amount of fat in the stools is large. Instead of an average of 15% being lost in the feces, but 7% escaped digestion during the 4 days the patient took bile. (3) That ox bile is a cholagogue. (4) That the effect of the bile on the bowels in this case was not remarkable, although they moved more satisfactorily during the bile period. (5) That urea and nitrogen were excreted in greater amount in the bile period than in either of the other periods. No definite conclusion as to the general effect of bile on body metabolism can be drawn from this fact that because more nitrogen was ingested during the bile period. (6) That the amount of urine was increased more than 50% during the bile period. Although the bile pills were coated with salol, the amount of that drug administered was not enough to produce this effect. On the other hand, in taking 30 pills daily the patient drank several extra glasses of water, and in the second experiment her general condition was naturally better than at any other time. [J. M. S.]

4.—Opie reports the case of a negress, aged 54 years, who died from diabetes mellitus. At the autopsy it was found that the pancreas weighed 80 grams, was soft in consistence and on section was of a gray-yellow color. Microscopically, it was found that the islands of Langerhans were the seat of a very remarkable change. In varying amount within almost every island there was a homogeneous material that stained with eosin. This hyalin substance at times lay in the midst of groups of cells, but was usually in contact with the walls of the capillaries penetrating the island, or next the peripheral fibrous tissue, and was therefore usually between the remaining cells and the capillary walls. The cells of the island were in large part replaced, so that between the hyaline particles only an occasional compressed fusiform or irregular nucleus

could be seen. The hyaline metamorphosis was strictly limited to the islands of Langerhans, the glandular acini remaining intact. In this pancreas, therefore, a lesion of obscure etiology has destroyed the cells of the islands of Langerhans, while those of the secreting acini, as well as those of other organs, are unaffected. The association of diabetes mellitus, the author believes, affords convincing proof that the islands of Langerhans are intimately connected with the glycogenic metabolism.—[J. M. S.]

THE PRACTITIONER.

March, 1901.

1. Etiology, Prophylaxis and Treatment of Malaria. PATRICK MANSON.
2. Malaria—Its Parasitology: with a Description of Methods for Demonstrating the Organism in Man and Mosquito. D. C. REES.
3. The Intermittant Fevers and Blackwater Fever. LOUIS W. SAMBON.
4. The Genus Anopheles. ERNEST E. AUSTIN.

1.—Patrick Manson discusses the etiology, prophylaxis and treatment of malaria from two points of view. First, the circumstances bearing on the introduction of the parasite into man; and second, the circumstances affecting the development of the clinical manifestations of malarial infection. Under the first head, he remarks that the knowledge that certain species of mosquito are the necessary media for malarial infection, has enabled us to completely and satisfactorily explain many facts which hitherto eluded us, such, for instance, as the long recognized association of malaria with high atmospheric temperature and paludal conditions. The danger of being out of doors at night in malarial countries is explained by the habits of mosquitos, which are mainly nocturnal. The value of the mosquito net and similar contrivances, of smoke, and of fire, as protections from malaria are explained by the circumstances that these things keep the blood-sucking insect at a distance. The etiology of malaria therefore, resolves itself in a great measure into the study of the natural history of certain species of mosquito. Especially the genus anopheles, which so far has been the only variety definitely proven to serve for the transmission for the parasite. The leading facts in the life of a mosquito are as follows: The egg deposited on still water floats on the surface or becomes attached to vegetation at the margin of the pool. In about two days a minute larva is hatched out and at once proceeds to feed greedily upon the organic materials suspended in the water. It grows rapidly and finally assumes the pupa form from which the perfect insect presently emerges. The duration of aquatic life varies with different species and is affected by the temperature of the water. In cold weather the development is entirely suspended. This hibernation of the larva is one of the ways by which the cold season is bridged across and the species carried over from summer to summer. The insect remains quiet during the day, feeding at night. The male is in most instances purely phytophagous. The female anopheles even in confinement will accept a meal of blood every 2 or 3 days. About 20 days after birth she deposits some 150 or 200 eggs, an operation repeated every few days so long as conditions are favorable. The entire cycle from egg to egg occupies about 50 days. It is calculated that a single female will give rise in four generations to a progeny of two hundred million. In confinement the mosquito has been kept alive for 2 months. Man is the great source from which the mosquito obtains the parasite. Under his second head, dealing with the circumstances affecting the development of the clinical manifestations of malarial infection, Manson mentions the important consideration of age, the young being especially susceptible, individual susceptibility innate or acquired, and such accidental occurrences as make for physiological depressions. Very few individuals are absolutely immune to the disease. Discussing the prophylaxis of malaria, Manson takes up the question of: first, suppression of mosquitos; second prevention of infection by mosquitos; and third, prevention of infection of mosquitos. Under the first head he discusses the abolition or, the prevention of, the formation of the special type of pool in which these insects breed. Subsoil drainage should be practiced wherever possible. The painting of stagnant water with petroleum is also mentioned. The prevention of infection of mosquitos should be secured by insisting that all malarial patients should

use mosquito net, at the same time endeavoring by the vigorous and persistent use of quinine, to remove the malarial gametes from the blood. Lastly, he discusses the value of preventing mosquito bites, and details the various experiments of Sambon and Low, Celli, Grassi and the Red Cross of Italy. These show very much can be done to prevent malaria in individuals living in notoriously malarious counties. He does not believe that Koch's method by drugging an entire community with quinine is feasible. As to treatment, quinine is the only reliable drug. He seems favorably impressed with the value of equinine. [T. L. C.]

2.—D. C. Rees has made a careful study of the parasitology of malaria, and presents an historical account of the development of our knowledge. The malarial parasite is now regarded as belonging to the class sporozoa, and closely connected with the coccididae. English observers have grouped the malarial parasites of man with those of birds into a separate sub-order, the hemamebidae. He presents a clever schematic illustration of the phases of development of the endogenous and exogenous life cycles of the malaria parasite. A convenient table is included in the article, showing the nomenclature employed by various writers for describing the stages of development of the malaria parasite. The technique of the demonstration of the malaria parasite in the blood is also given in great detail, and the author describes his method of breeding, transporting and infecting mosquitos. [T. L. C.]

3.—Lewis W. Sambon contributes a paper upon the intermittant fevers, and black-water fever. Under the phenomena of the paroxysm he describes the three distinct stages, the cold, hot and sweating stage, and presents a detailed account of the correlation of the parasites and the course of intermittant fevers. Especially interesting in that part of his paper devoted to multiple and mixed infections, in which he considers: 1, infection with several groups of the same species of parasites; 2, mixed infection, with a parasite of two or more types of intermittant fever; 3, complications with other diseases. Under this latter head he states that we now know positively that there is no such thing as a true "malarial pneumonia," but a pneumococcus pneumonia may occur in the course of a mild tertian or quartan infection. Siriasis may become a very grave complication of intermittant fever, and multiple neuritis may develop after an attack of intermittant fever. Black-water fever is described by Sambon as an acute infectious disease characterized by a sudden and intense hemolysis and clinically marked by irregular paroxysmal fever accompanied by rigors, bilious vomiting, jaundice and hemoglobinuria. In considering the etiology of black water fever Sambon concludes that the symptoms, the postmortem findings and the epidemiological features of animal fevers (referring to a hemoglobinuric fever found in sheep and other animals, in which an exceedingly minute parasite is present) are exactly like those of the hemoglobinuric fever of man. It is therefore quite reasonable to infer that black-water fever may be due to a protozoal organism akin to that of cattle red-water fever. We have as yet no remedy known to be of the slightest value in black-water fever. Sambon recommends a moderate dose of calomel followed by irrigations of the colon. He places more dependence upon the irrigations. Plenty of water may be allowed. In general the treatment is symptomatic. [T. L. C.]

ARCHIVES OF PEDIATRICS.

April, 1901. 18th Year, No. 4.

1. The Blood in Infancy and Childhood. ALFRED STENGEL and C. Y. WHITE.
2. Enteric Fever in Childhood. Wm. L. STOWELL.
3. An Unusual Case of Erythema Multiforme. FLOYD M. CRANDALL.
4. Decubital Ulcer in an Infant of Ten Months. VAN DERPOEL ADRIANCE.
5. Apparent Cure of a Case of Frequent Convulsions. Probably Epilepsy. ANNA R. LAPHAM.
6. A Case of Head-Nodding Associated with Spasmodic Torticollis. JOHN H. JOPSON.

2.—William L. Stowell reports 24 cases occurring in 19 family groups. Sixty-one cases of typhoid fever in children, of which the author believes that in many cases carelessness in the home caused the spread of the disease rather than an identity of origin. The youngest patient was 9

years old. The convulsions were not frequent, nor was delirium a constant symptom. Apathy and mental dullness are common in children, even the very young. Headache was often present, perhaps more in those with high temperature than in those without. Epistaxis is very common, usually during the first week. It is sometimes one of the very first symptoms and relieves the early headache. In 2 cases there was an almost universal eruption, which appeared about the time the temperature had reached its height. Beside the rose spots there may be other eruptions, such as erythema, herpes or sudamina. The compressibility and non-resistant qualities of the pulses are diagnostic. Both leukocytes and erythrocytes are diminished in number. If pneumonia sets in as a complication there is usually a great increase in leukocytes. The hemoglobin is greatly reduced, ranging from 25% to 60%. In 95% of cases the serum reaction is positive. Tympanites is less common in children than in adults. Gurgling at the iliocecal valve cannot be counted a diagnostic point. Excessive tympany is usually a precursor of death. If it develops very suddenly the possibility of perforation should be borne in mind. The author has not had a case of perforation in a young child, and from his experience he would infer that the hemorrhages are more common and more likely to be fatal in adults. Children are prone to be constipated during the first week, and usually have from 1 to 3 loose stools daily during the second week. Diarrhea was noted in 32.6% of the cases. A majority of these cases presented tender and enlarged spleens. Albumin was absent as a rule, but the diazo-reaction was found to be a helpful diagnostic test. Complications of typhoid fever in children include varicella, parotitis, pneumonia, intestinal hemorrhage and perforation of the bowel. Three of 77 cases, 16 of which were adults, had relapses. The average duration of the disease was 23½ days. The mortality in 61 children was nil. Milk diluted with vichy, seltzer or lime water and, if the fever is high, partly peptonized, is the best diet. Lemonade, iced coffee and iced cocoa may be used freely; ice cream is also allowed. Intestinal antiseptics is of prime importance. Salol is the author's favorite drug; but he has also had good results from the use of the well-known tablets of podophyllin, calomel, guaiacol, menthol, etc. He has never aborted a case thereby. During the third week, the soft compressible pulse of a flagging heart needs help; strychnine, digitalis, camphor and ammonia may be used for this purpose. He does not give alcohol to children; although he uses liquid peptonoids freely. Occasional doses of antipyretics may be given in certain cases and be very helpful; but their effect on the circulation should be watched. Children do not show the same benefit or even tolerance of tubing that adults do, and the author relies on sponging. [J. M. S.]

3.—Floyd M. Crandall reports the case of a boy, aged 8½ years, who had been healthy, but who became ill with fever and sore throat. On the fourth day of the disease a **multiform erythematous rash** had developed that involved the entire body. A culture made from the throat was contaminated but contained no diphtheria bacilli. Recovery was complete and there has been no recurrence. [J. M. S.]

4.—Vanderpoel Adriance reports a case of duodenal ulcer in an infant, 10 months of age. The diagnosis was confirmed at autopsy. [J. M. S.]

5.—Anna R. Lapham reports the case of a girl, aged 2 years and 4 months, who had **frequent convulsions**. During a 3 weeks' residence in hospital 387 attacks are recorded. The child's father was nervous and her mother was a neurasthenic. The mother, in addition, had convulsions when a child of 3, which were followed by paralysis. Treatment by bromides, tincture of *passiflora incarnata*, trional and codeine had reduced the number of the convulsions, when the mother took the child away. The convulsions immediately returned and a paresis developed. Later, the child was sent to the country and all medication was abandoned, and under the care of a trained nurse who regulated the patient's diet the convulsions and the paresis disappeared and the child has been well for months. The author believes that the etiology of the condition is traceable to a **toxemia due to intestinal ptomaines**, although there was a history of a fall. Of course, heredity must have played some part in the development of the condition. [J. M. S.]

6.—John H. Jopson reports the case of a female infant, aged 11 months, who presented **spasmodic torticollis** due to right-sided contraction of the sternomastoid muscle, ac-

companied by **head-nodding**. One month before the patient was seen, she had fallen down stairs and the following day developed a bronchitis. The torticollis and head-nodding were noted after recovery from the attack of bronchitis. The condition improved under treatment by small doses of tincture of belladonna. [J. M. S.]

JOURNAL OF NERVOUS AND MENTAL DISEASE.

March, 1901. [No. 3.]

No. 1. The Amelioration of Paralysis Agitans and Other Forms of Tremor by Systematic Exercise.—JOHN MADISON TAYLOR.

No. 2. A Case with Symptoms of Cerebro-spinal Meningitis, with Intense and General Alteration of the Nerve-Cell Bodies, but with Little Evidence of Inflammation. WILLIAM J. SPILLER.

No. 3. A case of Muscular Dystrophy. CHAS. GILBERT CHADDOCK.

1.—Taylor has studied the effects of systematic exercises and massage in various cases of **paralysis agitans**. He reports in detail one case. A man of 52 had been afflicted with the disease for about 7 years. The rigidity gradually became so extreme that the only voluntary motion preserved was the festinating gait. There were pronounced contractures in the tissues of the trunk and neck, and exaggerated cervical and dorsal curvatures of the spine; even the power of articulate speech was lost. The exercises were continued for six months, and consisted of massage of the thickened rigid skin, passive extension of the contracted muscles, and gradually increased voluntary movements. There was at first considerable pain, then tingling, and finally a pleasurable sensation after the exercises. The patient was able to write and to speak, and was also capable of performing light tasks. Taylor believes that the points to be observed in this form of treatment are the re-establishment of the largest degree of elasticity in the tissues which have suffered contractures, which should be obtained by passive extensions and flexions followed by active movements. As far as possible the normal attitude and carriage should be restored. [J. S.]

2.—The patient, a boy of 8, an idiot with spastic gait, was suddenly attacked with fever, pain and diarrhea. He developed photophobia, hyperesthesia of the skin, sluggish reaction of the pupils, which gradually gave way to immobility of the pupils and retraction of the head. He developed coma and died, 6 days after the appearance of the first symptoms. At the autopsy a petechial eruption was observed on the thighs; there was edema of the brain, no distinct evidences of inflammation of the membranes, and miliary tubercles. The internal organs were apparently normal. Microscopically no evidence of inflammation of the nerve tissue was discovered, but extensive degeneration of the nerve cells in the entire central nervous system. There was a slight round celled infiltration of the pia mater of the spinal cord. This condition has been reported in two other cases; one published by Spiller and McCarthy, was a case of internal hemorrhagic pachymeningitis in an idiotic child, and the other by Hirsch and Sachs, a case of amaurotic family idiocy. Numerous bacteria were found in the nervous tissue, which were probably present before death. It is not certain that this is a case of intoxication. [J. S.]

3.—The patient, a man of 39, without a significant family history, had never been able to whistle. At the age of 15 he first noticed that he was not able to close his eye-lids completely. At the age of 24 there was distinct weakness of the right arm, which gradually extended to the left arm. Nevertheless, he was able to continue his occupation of machinist. Finally, however, increasing feebleness compelled him to give up that occupation. His present condition is one of muscular wasting, involving the muscles of the face, with the exception of the muscles of mastication, the shoulder, the arms and the thighs. The fore-arms, legs and abdomen are fairly well preserved. The weakness on the right side is greater than that on the left side. There is very marked emaciation, and the muscles that are still normal in size have a curious wooden-like consistency. The patient has evidences of senility, that is to say, there is an arcus senilis, and he has suffered from presbyopia for several years. [J. S.]

5. Pernicious Anemia—With an Analysis of Eighty-seven published Cases, and an Inquiry into the After-History of Twenty-two reported Cures. HORACE C. COLMAN.

1.—Croom reports several cases in which mental disturbances occurred after gynecologic operations, which were uncomplicated and simple, and in which the operation *per se* was entirely successful. In another group of cases major operations were performed. The cases developed in women who, so far as could be traced, had no hereditary tendency to insanity. Undoubtedly the first factor in the production of post operative insanity is heredity; the second, is sepsis; and the third group of causes, such as loss of blood and defective action of the kidneys. It seems probable that the essential prerequisite for the development of postoperative insanity must be a neurotic organization predisposed, either from hereditary taint or acquired nervous weakness and instability, to take on diseased or perverted action in consequence of any disturbing influence. Under no circumstances ought any insane woman to be operated upon unless for some distinct condition that is compromising life. [J. M. S.]

3.—A benign acute disease is one in which the natural tendency is towards recovery and in which our efforts are directed to keep the patient alive until the disease has subsided. In such cases the nutritive condition and the state of the blood and the tissues are the really dominant factors in the maintenance of life. On the other hand, there are cases of acute disease that do badly from the outset and progress steadily until life is destroyed. As simple examples of this class, we may take acute tuberculosis and the acute form of ulcerative endocarditis. Such acute diseases are malignant by their very nature. There are other disorders which, although benign in some subjects, are malignant in others, such as erysipelas in the old and feeble and acute catarrhal pneumonia in debilitated persons. The diagnosis between the benign and the malignant forms of the same acute disease is then of great importance. The malignancy may depend in some cases upon the varying virulence of an infective disorder in different outbreaks, such a disease as scarlatina, or even measles appearing sometimes in a severe form, and proving fatal to the healthy. But more commonly in the case of an ordinarily benign disorder, the malignancy is due to bad reaction on the part of the subject. A true diagnosis is the first condition of prognosis. Inheritance has much bearing on prognosis. Some families show a poor vitality, and when an epidemic disease attacks the children, they die off rapidly. In other stocks the physique may be far from robust, and yet the members are tough and pull through illness successfully. The history of the patient has an obvious bearing, for example, alcoholism hinders recovery from every kind of acute disorder. Other factors that Fox considers as having a bearing on prognosis are, general physique and habits, temperament, the condition of the circulatory organs, the respiratory organs, the digestive organs, the skin and the kidneys. [J. M. S.]

4.—Whyte believes that recent researches show that the stimulant effect of alcohol on the brain, the heart, and the muscles, if existing at all, is very brief, lasting probably only a few minutes. The apparent effect of the drug in stimulating respiration needs further investigation as to its mode of causation. On the tissues, alcohol acts as a protoplasmic poison, and this must be borne in mind if we are to use alcohol for its nutritive value. Clinical observation has been, on the whole, moving along parallel lines with the researches in the laboratory, and there has been a marked tendency in recent years to restrict the administration of alcohol as a medicine. As regards the whole class of diseases of the nervous system, there are few who would

expect any benefit from alcohol except of a sedative or narcotic character. The great mixed mass of mental diseases, as found in asylums, are best treated without alcohol, whatever the cause or nature of the case. In some cases of simple dyspepsia a little alcohol with a meal, well diluted, is found to give relief often, no doubt, through its sedative action on the nerves or it may be by increasing the secretion of gastric juice and thus aiding digestion. Other gastric conditions, such as catarrh and ulcers, as well as all intestinal disorders, are better treated without alcohol. Liver disorders are probably in all cases prejudicially influenced by alcoholic beverages. In kidney diseases of all kinds alcohol should be rigidly withheld. In no class of diseases is alcohol more generally considered indispensable than in septic cases, puerperal fever particularly its value is questioned. Alcohol is recommended in croupous pneumonia as a food and as a stimulant. The brief stimulating effect of alcohol, such as it is, is to be measured by about 15 minutes, after which comes a prolonged period of depression. The food value of alcohol in pneumonia need hardly be taken into account. These facts should give pause to the employment of alcohol in this disease. The complication of pneumonia with inebriety is very grave, and it has been a widely accepted dictum that alcohol must be given in such cases; but it has been proved best in cases of delirium tremens or habitual alcoholism to stop the alcohol at once and completely, therefore why should it be continued where an infectious disease is engrafted on an intoxication. [J. M. S.]

5.—Will be abstracted when concluded.

BRITISH GYNECOLOGICAL JOURNAL

February, 1901.

Inflammation of the Fallopian Tubes.

E. STANMORE BISHOP.

1.—Bishop gives a comprehensive paper on inflammation of the Fallopian tubes with illustrative cases. He remarks that ever since it became possible to diagnose salpingitis as distinct from inflammations of the pelvic connective tissue it has been recognized that in certain cases suppuration occurs; that the pus thus formed distended the closed tube; and that the tube thus became converted into an abscess-sac of which the ovary might or might not be a part, the presence of which was a continuous menace to the life of the patient. For the removal of this pus-cavity operators have been divided as to which operation is the best, the vaginal or the abdominal. Those in favor of the vaginal route claim that the tube tends to sag downward from its own weight into Douglas' pouch, and can most easily be reached by a posterior kolpotomy. An opening thus made gives vent to the purulent accumulation and permits of its free escape without interfering with the contents of the abdominal cavity. Bishop, however, claims that various improvements in the abdominal operation have rendered that the operation of choice. Especially is this true of the Trendelenberg position. The increased view of the field enables the operator to proceed more cautiously and more correctly. Also, the doing away with the drainage-tube has removed the most potent cause of subsequent ventral hernia. His illustrative cases are of the severe type, and show the conditions for which the surgeons should be prepared who propose to attack a case of pyosalpinx by the abdominal route. [W. A. N. D.]

8. Investigations Concerning the Depressing Effects upon the Temperature of some Convulsive Poisons. By HARNACK, assisted by H. DANNIAR and J. STARKE.

1.—Loewi presents a series of investigations concerning nuclein metabolism. His conclusions are that the nucleins of the food are partly broken up in the intestine, the phosphoric acid of the separated portion being excreted in the feces while the nitrogenous portion is absorbed. The major portion of the nuclein is, however, absorbed in toto, the phosphoric acid remaining in organic combination. It is possible by feeding nucleins to cause a nitrogen and phosphoric acid retention in the same ratio in which these substances are contained in the ingested nucleins. The addition of nucleins to the food, under some circumstances, increased the retention of nitrogenous substances and also of phosphoric acid. With the exception of uric acid no specific nitrogenous or phosphorous-containing end products of nuclein destruction appear in the human urine in recognizable amounts. The ingestion of guanin, combined with nuclein, results in marked increase of the uric acid excretion. The uric acid excretion is normally purely dependent upon the food taken. The observation concerning the influence of nucleins in causing a nitrogen and phosphoric acid retention is a very notable one, and one that is very difficult to explain. It is an observation that is supported, however, by the work of other observers referred to, the only contrary results being found in the work by Milroy and Malcolm, who found a loss of nitrogen and of PO. The preparation they used was, however, probably toxic in its effect, and the condition was therefore not caused by the nuclein itself. The statement that uric acid is the only end product of nuclein disintegration found in the urine is based upon coincident observations of the nitrogen, uric acid, and P O. excretion. There were no determinations of the amount of xanthin bases, and it is quite possible that these bases may have been present in considerably larger amounts than normal. The final conclusion that the uric acid excretion is normally dependent purely upon the food is in direct opposition to the recent statement of Burian and Schur, who insist that there are in normal persons decided differences in the amount of uric acid excreted; that there is, in other words, an individual disposition observable in relation to the uric acid excretion. Loewi criticises the statements made by Burian and Schur, which are certainly contradictory in many particulars, and are rather strongly fenced about with conditions. Loewi's own statement is based upon his observation of three persons who were excreting practically the same amount of nitrogen and the same amount of PO. The uric acid in these persons was directly proportionate to the nitrogen ingestion. He insists, therefore, that if normal persons are put under exactly the same conditions of metabolism, the excretion of uric acid will be practically exactly the same in all normal individuals. [D. L. E.]

2.—Gerhardt's article refers to the question whether in cases of mitral lesion the enlargement of the right heart is really a compensatory change, or whether it is purely a result of the extra work thrown upon the right heart. Basch and his students claim that the right heart does not compensate for the mitral lesion, but that it merely hypertrophies in order to carry out properly the extra work which has been thrown upon it and to keep from failing in its own work. The three questions which Gerhardt attempts to answer in this connection are: First, Whether, as Basch states, swelling and rigidity of the lungs constitute the chief unfavorable results of the mitral lesion or whether the most important unfavorable influence is really imperfect flow of blood into the left ventricle; second, What means are there for increasing the flow of blood into the left ventricle; third, can increased labor on the part of the right ventricle actually increase to the normal point the blood pressure in the larger circulation, which in mitral cases is below the normal. Gerhardt has carried out experiments which he details at length, and which convince him that while there is some actual reduction of the amount of air inspired when the pulmonary vessels are over-full, this is so slight that it is by no means sufficient to explain the severe respiratory disturbance which is seen in cases of mitral disease. The real cause of the disturbance of respiration, and of the other main symptoms in mitral lesions, he thinks must be considered to be imperfect supply of

blood to the various organs. Compensation of the mitral lesions would therefore be furnished if the disturbance of the blood flow through the mitral orifice were in any way improved. The only way in which the blood flow could be improved would be through increasing the pressure in the auricle as compared with that in the ventricle. Gerhardt thought that it was possible that the suction action in the left ventricle was sufficiently increased in cases of mitral stenosis to succeed in some degree in compensating for the lesion. Were this the case, one would expect some degree of hypertrophy of the left ventricle, even in pure mitral stenosis. This he was unable to show. It is well known, however, that the auricle itself does hypertrophy, and this furnishes some compensation; it is only an imperfect compensation, however, particularly in stenosis with regurgitation, and the auricle soon fails in carrying out the work put upon it. He reports another series of experiments in which he largely increased the pressure on the right side of the heart, and consequently in the pulmonary vessels, and determined the pressure in the larger circulation (in the carotid). He found that the carotid pressure could be distinctly increased by increasing the work of the right ventricle, though the increase in the carotid pressure was much less than the increase in the pressure of the pulmonary arteries; he decides that increased work on the part of the right ventricle can to some extent compensate for a mitral stenosis, and he believes that the hypertrophy of the right ventricle seen in these cases is a real phenomenon of compensation. Another way, and this is evidently purposeful, in which the flow of blood through the mitral orifice is made more complete, is by slowing the heart beats. One may frequently observe in mitral stenosis that the pulse is unusually slow. As a general conclusion, he states in which the flow of blood through the mitral orifice is made more complete, is by slowing the heart beats. One may frequently observe in mitral stenosis that the pulse is evidently purposeful. As a general conclusion, he states that one may consider the changes seen in the right ventricle to be actual compensatory changes, and although there are certain unfortunate collateral results connected with these compensatory changes, he does not believe that the most important alterations seen in mitral lesions are swelling and rigidity of the lungs, and the consequent interference with respiration. The changes in the lungs are rather due to changes in the vessel walls resulting from the constant high pressure in these vessels. [D. L. E.]

3.—Magnus refers to the work that has already been done, particularly by Starling. The latter author attributes the diuresis seen after injection of salt solutions to the plethora supposed to be produced by these injections. Magnus believes, on the contrary, that his experiments do not justify this conclusion, and that the diuresis is rather due to a change in the constitution of blood after the injection; that the diuresis is due, in other words, not really to the injection of fluid, but to the amount of salts introduced into the blood. In order to study this question further he made transfusions of blood itself, of the same species, without defibrinating. He found that transfusing from 33 per cent. to 70 per cent. of the entire quantity of blood contained in one dog into another, resulted in no serious symptoms. Urine was excreted in just about the same amount after the transfusion as before; in only one instance was there any notable increase in the urine. Hence he decides that transfusion causes either no increase in the urine or an extremely slight increase that is not worthy of any attention. He then raises the question as to whether there was really an increase in the total quantity of blood after the transfusion, or whether a good deal of the fluid passed into the tissues. He answers this question by reporting hemoglobin estimations which he made before and after transfusion. The total amount of blood in the animal was taken to be 7 per cent. of the body weight, and reckoning the total amount of blood before and after the transfusion, and taking the hemoglobin contained in the blood before and after, he decided that there was a decided increase in the amount of blood, though this was not fully equal to the quantity injected. The increase in the amount of blood varied: the smallest increase was from 100 up to 117, the largest from 100 up to 195. He believes, however, that the tables presented show that there was an actual increase in the amount of blood, in other words a plethora and that this did not increase the excretion from the kidneys. He believes that the explanation of the apparent passage

of a portion of the fluid into the tissues must be found in filtration. The blood was the same as that of the animal injected, and diffusion or osmosis can therefore not be made answerable for the phenomenon. There is no reason for considering that there is any such thing as an increased secretory power of the capillary cells, consequently filtration is the only explanation. It was remarkable how rapidly this filtration took place. The effect of the transfusion was to raise the blood pressure greatly, the arterial pressure going from 100 to 150, and the venous pressure showing as marked a change as from 60 to 160 within 10 minutes. The question as to whether the capillary pressure in the kidneys was raised in this general increase of pressure was investigated by means of the onkometer. There was a distinct increase in the volume of the kidneys which gradually increased to the normal. This does not demonstrate definitely, however, that there was an increase in the capillary pressure, but it does demonstrate a general increase of pressure, and shows that there is no vaso-constriction of the kidneys in transfusion. To demonstrate that change in the composition of the blood will cause increased diuresis after injections of salt solutions, animals were given first an injection, a solution of Glauber's salts, and directly afterward a transfusion of blood. In these cases there was a marked increase in the urine excretion. The general conclusions reached were that transfusion, without changing the constitution of the blood, causes a marked plethora with increase of the arterial, venous and capillary pressure, and in the general volume of the kidneys. This is associated with the passage of fluid into the tissues, but not with diuresis; while with a change in the character of the blood diuresis follows. Plethora cannot be considered to be the cause of the diuresis after injection of salt solution; the diuresis is rather due to change in the constitution of the blood. [D. L. E.]

4.—Gottlieb and Magnus conclude that in some cases there is no very marked parallelism between diuresis and changes in the kidney circulation. This is chiefly seen when the diuretic acts rapidly and temporarily, while if the action be prolonged or frequently repeated, this relation between circulatory changes and diuresis is not observed. Diuresis may occur without any increase in the blood flow. In some animals after a single dose of the diuretic the excretion of urine and the amount of blood flowing through the kidney were not parallel. This was chiefly the case in chloralized animals, and was perhaps due to the influence of the chloral. They observed, on the contrary, that increased readings of the onkometer were seen without a coincident diuresis. They therefore conclude that there are very complicated relations between the activity of the kidneys and the circulation through these organs, and that their experiments do not allow them to conclude that there is any casual relation of increased circulation to increased diuresis, and the changes in the circulation cannot be considered to be *primum movens* for the diuresis. The conclusion, which they believe is justified, is that rapid circulation through the kidneys is as a rule an accompaniment of active functioning of these organs, and a free circulation is usually associated with free diuresis, but a large amount of blood in the kidneys does not always mean a very marked activity of these organs. They conclude that the diuretic effect of caffeine is due to the influence of this drug upon the secreting apparatus of the kidney, and not due to its influence upon the circulation and the kidney. Finally, they state that the cause of diuresis is really in the first place in the increase of one or more of the blood components above a certain point. This occurrence results in the active secretion by the kidneys of the excess, and this is accompanied by the excretion of considerable portion of water carrying these portions in solution. They think that it is possible that the diuresis in such instances occurs merely passively without any special cell action, and that the kidneys really act as a filter which works only when the concentration of the blood goes above a certain point. This is, however, very improbable. It is much more probable that there is a marked selective activity of the kidney cells, which is greatly increased in normal subjects by any increase in the blood concentration. [D. L. E.]

5. After detailing their experiments, the authors discuss their results, and state that during diuresis there is very frequently to be observed a decided increase in the ureteral pressure and this is certainly due to the diuresis when it occurs, but exactly in what way it is caused is not

clear. The fact that increase of the ureteral pressure does not occur regularly with diuresis indicates that there are complicated relations between the two. It is certainly not due directly to changes in the blood pressure. It is more probably dependent upon the excretory activity of the kidneys and the suction filtering action of the organ, and therefore dependent upon two variable factors. They think it is very probable that there is a relation between pressure in the ureters and the activity of the secretory elements of the kidneys. [D. L. E.]

6.—The authors refer to the fact that 3-methylxanthin has not previously been found in human urine, even when Krueger and Salomon determined the xanthin bases present in 10,000 liters of urine. Hence they decided that theobromin did not produce 3-methylxanthin in man as it does in animals, or that in the hospitals from which the 10,000 liters of urine were obtained the patients were receiving food that either contained no theobromin, or contained so little that it had no influence upon the constitution of the xanthin bases found. The investigations reported here showed, however, that after taking 9.3 grams of theobromin, 1.513 grams of heteroxanthin were obtained, and 0.796 grams of 3-methylxanthin; in other words, that theobromin in man furnishes for each 100 parts about 8.56 grams of 3-methylxanthin, and probably even more; hence the human organism behaves in the same way toward theobromin as do the organisms of lower animals. [D. L. E.]

7.—The case reported was that of a man of 61 who had emphysema, bronchitis, arteriosclerosis, with diarrheal attacks and associated with marked distension of the abdomen, but unassociated with either tenesmus or the passage of mucus and blood. Microscopic examination showed great numbers of coccidia-like bodies. The patient's condition was somewhat improved by giving him yeast, but he was made worse by calomel. No further special medication was undertaken in connection with his intestinal trouble, as his general condition would not allow of active intervention. Death soon occurred. The post mortem showed some injection of the mucous membrane of the intestine with occasional ecchymoses, and slight swelling of some of the follicles. The patient died of edema of the brain and encephalomalacia. The bodies described are very attractively pictured in an accompanying illustration. They were usually from 6 to 8 micrometers in diameter, the largest being 12 or 13 micrometers in diameter. There was a slightly greenish shining homogeneous body with a delicate capsule; the body was round, and occasionally seemed vacuolated. Some of the bodies showed nuclei and some did not. Occasionally two nuclei could be seen. At times there were two bright points seen on the periphery diametrically opposite to each other. These strongly resembled the polar bodies seen in karyokinesis. Lugol's solution had no effect, and the bodies took stains in general, badly. Methylene blue gave a poor stain, but a much better stain was obtained with carbolfuchsin. Hematoxylin gave imperfect results. Sections from the intestine showed the bodies to be present in the lumen and in the mucosa, but only near the surface of the latter. The bodies seemed to be coccidia, but this could not be definitely determined. They were thought to be most probably, however, coccidia *blumina* because of their general appearance and the position in which they were found. Their pathogenicity was doubtful, but it was thought that they were pathogenic because of the fact that some histological changes were nearly always found in the areas where they were present in considerable numbers. This chiefly consisted in loss of epithelium, flattening of the cells, and frequently marked infiltration with leukocytes. [D. L. E.]

8.—Harnack contributes an extensive report that is of general interest only in so far as it shows that santonin reduces the rectal temperature through increasing the heat loss, and that the latter is due to dilatation of the peripheral vessels. The alteration of the vessels is constant, and coincides with the depression of temperature. The fall of temperature does not occur if increase of the blood loss is prevented, and if the heat loss is not increased. The fall of temperature is not occurred if the vaso-dilating effect of santonin is antidoted by the administration of atropine. The action of santonin is more complicated when doses are given of such a size that they produce convulsions, as in such cases much more heat is produced. The result then depends upon individual factors, such as age, size, and the species of animal. In young or small animals, in spite of protracted convulsions subnormal temperature, is found to be persistent. The effect of santonin is much more dangerous when increased

loss of heat is rendered impossible by keeping the animal in a high temperature. It therefore seems probable that the increased heat loss is a method of protecting the organism against the effect of the convulsive poison. [D. L. E.]

1.—Pick reports the following cases. The first, a woman of 29, who had been sick for a year with slight jaundice, had chills followed by fever, sometimes with, sometimes without pains in the abdomen, and appearing at regular intervals. In a period of 6 months 46 of these attacks occurred. Subsequently there was apparently complete obstruction of the bile ducts, ascites and death. A gallstone was found that had been impacted in the common duct, and had broken through into the duodenum. There was biliary cirrhosis of the liver. The second patient, a woman of 53, had an attack of typhoid fever in 1892, then had severe pains in the abdomen followed by the passage of numerous faceted gallstones. The liver was slightly enlarged, and at intervals of 2 or 3 days she had attacks of chills followed by fever, and usually accompanied by abdominal pain. The liver was enlarged, and there was slight jaundice. Subsequently she improved, and became entirely well. Careful investigations of the urea in this case showed that during these attacks it was diminished, apparently as a result of diminished formation, although according to the present status of the ammonia theory this could not be positively proved, because neither the ammonia nor the total nitrogen was diminished. It seems therefore reasonable to conclude that the products of the albuminous metabolism are not conveyed to the liver in the form of ammonia salts but in some other form which cannot be excreted by the urine. In regard to the diagnosis of intermittent biliary fever Pick gives the following points. The regular intermittent fever; the prolonged course; the absence of any signs of acute inflammation; particularly the absence of leukocytosis during the attacks, and the very marked reduction in the elimination of urea in the urine, which is contrary to the usual marked increase during febrile conditions. The prognosis is rendered very grave by the occurrence of this form of fever, but not hopeless. The most unfavorable complication is the development of biliary cirrhosis. [J. S.]

2.—The patient, a woman of 74, had suffered for 15 years with pain in the right hypochondrium. Nevertheless she had remained in good health. One morning she awoke with nausea, and vomiting of blood. This was repeated; the patient rapidly became weak, and died in the course of the day. The autopsy was made 32 hours later, and there was found bilateral lobular pneumonia, parenchymatous nephritis, hemorrhagic and biliary cirrhosis of the liver, and marked cystitis. In addition the liver was spongy, crepitant, contained numerous fine bubbles of gas and showed the characteristic changes of cirrhosis; microscopical examinations revealed numerous short rod-shaped bacteria that upon cultivation proved to be the bacteria coli communis, proving that gas-formation can be produced by various microorganisms. [J. S.]

3.—Elsner has performed a very elaborate series of experiments in order to determine the amount of methylene blue that is excreted from the body. The blue was administered and then the amount excreted in the urine and intestines determined by colorimetric methods. These are necessarily somewhat inexact, but control showed that they were accurate enough to determine within a few per cent. In 4 cases it was found that the total quantity excreted averaged about 68% of the quantity ingested. The

remaining methylene blue is probably either decomposed by bacteria or retained in the body. This is particularly likely to be the case if there is any dead tissue near, as for example, in a case of general amyloid disease, in a case with gangrenous ulcers, and a very low per cent. of excretion was found in a case of severe gastro-intestinal atony which improved as the latter was benefited. [J. S.]

4.—Grassmann in continuation of his article, reports 2 cases in which pericardial murmurs appeared in the course of syphilis, in one, heard best over the apex and disappearing when the patient lay down, and in the other, best heard over the pulmonic area. He also reports 96 cases in which there was alteration in the outline of the heart. In 79 of these there was dilation of the right ventricle; in 8, dilation of the left ventricle; and in 9 cases, of both ventricles. He gives the histories of a number of these cases. In many of them symptoms of relative mitral insufficiency developed in the course of the disease. In some cases these are possibly due to the alteration that takes place in the blood in the secondary stage of syphilis. Nevertheless, this cannot be always true, because in some cases in which relative insufficiency exists, the hemoglobin may be present in great quantities, or only slightly reduced. It is interesting to note that from time to time the outline of the heart may change considerably. (The paper is still unfinished.) [J. S.]

5.—Kaufmann reports the case of a man 30 years of age, who had convulsions at the age of 3 years, and subsequently suffered from a slowly progressive paralysis. There were no disturbances of sensation, or of the functions of the sphincters. The reflexes persisted, and there was no degeneration in the muscles, but greatly diminished response to electric stimulation, and indications of fibrillary contractions. There was a luetic infection, after which the right arm became paralyzed; there was tenderness along the surface, and slight fever. This was improved by anti-luetic treatment but not completely cured. The case therefore presents a progressive muscular dystrophy associated with paralysis of the serratus muscle as a result of syphilitic neuritis. Kaufmann has undertaken a series of exact measurements upon this, and upon 3 other cases according to the method of Mollier, in order to determine the various combinations of paralysis that occur in the muscles of the shoulder girdle. It is impossible to go into the details of these, but the results show paralysis in the right shoulder, of the pectoralis, of the rhomboidei of the serratus, and of the serratus in the left shoulder. The elevators of the clavicle and the scapula, and the upper trapezius were approximately implicated on both sides. In conclusion he mentions a fifth case in which the right shoulder was very much higher than the left, and the scapulae occupied a curious oblique position. Measurements showed that this was probably due to paralysis of the rhomboidei. [J. S.]

6.—Jesionek reports the case of a woman 56 years of age, who developed an eruption of reddish spots upon the body associated with swelling of the knees and ankles. The joint symptoms rapidly disappeared but the eruption remained in the form of pea-sized spots of brownish color slightly depressed, that gradually disappeared to be replaced by a new group in the course of 5 or 6 weeks. The spots were not painful nor irritating in any way. The fact that they appeared on the face caused such discomfort of mind that she could not sleep and rapidly emaciated. When examined it was found that the head, neck and mucous membranes of the throat were all involved, whilst only some old spots, indicating a previous eruption, could be distinguished below the waist. Three types of eruption were detected, the first, pea- or cherry-sized, sharply circumscribed and projecting from the surface. These had a brownish-red color; the surface was glistening, their consistency was somewhat like that of putty, and they were slightly translucent. Another type were flat papular brownish-red bodies, round or oval; these were somewhat softer than the others, and also glistening. Finally there was a group of small irregular nodules about the size of a pin-head, pink in color, slightly projecting, and closely resembling the eruption of acne. Numerous intermediary forms were also observed. Microscopically these bodies showed a tumor-like infiltration starting from the middle of the corium and extending into the center of the bodies. Most of the cells apparently resembled lymphoid cells, others however, were large and oval and resembled epithelioid cells. Numerous giant cells were also present. How-

ever, nothing resembling tuberculous growth was found. Treatment consisted in the careful curettement of all the diseased bodies, and then touching the raw surface lightly with the actual cautery. Perfect recovery ensued with very small scars. The case evidently resembled *acne telangiectodes* as described by Kaposi, and apparently represented a degenerative process of the epithelium of the hair follicles. [J. S.]

7.—Reineboth has performed a number of experiments in order to determine the macroscopic results of *contusion of the lungs and pleura*. When the pleura was exposed and bullets of various weights dropped through glass tubes 50 cm. long, it was found that even if weights of 2 grams were employed no microscopic effect occurred in either the lung or the pleura, proving that the pulmonary tissue is not very vulnerable. Similarly it was impossible by striking upon the pleximeter laid upon the exposed ribs, to produce a suggillation of the pleura. Weights of 20 grams or more were also dropped upon the exposed thoracic wall from a height of 60 cm.. It was found that suggillation rarely occurred if the first, second, or third ribs were struck; never when the 3rd to 5th ribs were struck, and not infrequently when the 5th to the 8th rib was struck, proving that the thin edge of the lung was more vulnerable. When a hammer was used it was found that suggillations could be produced in any part of the lung. They were diffuse and particularly severe in the lower portions. When the movable ribs were struck it required considerable force to produce the suggillations. When the blows were made upon the back either upon or near the spinal column suggillations were sometimes but not frequently produced. These occupied the apex of the lung and sometimes extended along the course of the ribs. Contusion of the lung could not be produced by blows, however severe, upon the epigastrium, and the effect of the period of the respiration rhythm was not observed. Reineboth considers that the results cannot be applied directly to human pathology, but hopes that they will stimulate more careful observations of the results of contusion in man. [J. S.]

8.—Freudweiler has performed an elaborate series of experiments in continuation of those abstracted for the *Phila. Medical Journal* from the previous number of the *Archives*. In that paper he studied particularly the histology of artificial topi produced by the injection of biurate of sodium into the tissue. A number of questions were, however, raised regarding the cause of spontaneous topi. Among these he mentions particularly the idea that they are produced by some local alteration in the tissue that is associated with general defect in the chemistry of the body. This local effect upon the tissue may be produced by the trophic influence of the nervous system, and this influence upon the tissue may be produced by an action upon the central nervous system of the defective blood (the so-called neurogenic theory), or the local alteration may be produced by local congestions. The predisposing causes are of course the familiar ones of alteration in the alkalinity of the body juices. Finally the local alteration may be produced by some injury or disease of the part, or gout may be an infectious process. In order to elucidate these points Freudweiler has performed a number of experiments in which he has attempted to saturate the body juices with uric acid, chiefly by the ligation of both ureters, and then to promote the deposit of urates by local injury, or by alterations of the chemical reaction of the tissues. In a series of preliminary experiments he found that the tissues of the hen do not react as vigorously to uric acid as do those of the rabbit. He also experimented with the xanthin and hypoxanthin bodies and found that they were both more poisonous than uric acid. Various of the preliminary bodies formed in the synthetic production in uric acid, particularly ammonium lactate and glycol, also produced considerable local irritation, and the same was true of hipuric acid, kreatine and kreatinine, and uric acid. All these experiments seem to prove that the formation of uric acid from various other substances was not possible, but that the topi were composed of uric acid deposited as such. Neither uric acid nor any of these other bodies apparently were capable of producing an additional deposit, even if the uric acid contents of the blood was increased, and the same was true of increased alkalinity, or local necrosis caused by the actual cautery. When, however, there is a great excess of uric acid in the juice it was found that it was deposited in the following organs named in the order of frequency: The pericardium, the pleura, the periton-

eum, the kidneys, the liver, the stomach, the heart,, the fatty tissue of the abdomen, and the muscles. It is rarely deposited in the joints or tendon sheaths. The serous membranes are much more frequently affected than the others, and usually there is some inflammatory change in the neighborhood of this infiltration. It seems likely, however, that acute inflammatory processes have a tendency to promote a deposit of uric acid crystals, and the fact that the synovial membrane of the great toe is commonly injured in these days, may explain the greater frequency with which this place is affected in gouty attacks. Freudweiler, however, particularly avoids suggesting any new theories, but he believes as a result of his experiments that we may reasonably assume that gout is a constitutional disease characterized by an increase in the uric acid in the body juices. This has a tendency to promote the occurrence of local infections, and when these occur coincidentally with the maximum proportion of uric acid in the blood there is a local deposit of crystals. These deposits relieve the tissues for awhile, until there is again a local infection with maximum proportion of uric acid. [J. S.]

9.—Strupler calls attention to the great difficulty of diagnosis in disease of the pancreas associated with septic processes. He reports two cases, one a man of 44, who was brought to the hospital unconscious with the history that he had suffered for some months with a feeling of discomfort in the abdomen and thorax and had suddenly fallen unconscious on that day. There was bilateral tuberculosis, endocarditis and embolism in the left cerebral hemisphere, there was some distension in the abdomen, and a trace of albumen in the urine, but neither blood nor sugar. He died 6 days after admission. In addition to the conditions recognized clinically, there was fat-necrosis of the pancreas. In another case the patient, a very obese woman, had suffered for 25 years with pain in the abdomen just beneath the ribs. She was slightly edematous, had extreme tenderness in the epigastric region; the urine contained a trace of albumen and of sugar. She gradually developed a sense of resistance in the abdomen, had a septic temperature and died. The feces did not contain an excess of fat. At the autopsy there was necrosis of the pancreas going on to gangrene and internal pachymeningitis. Broncho-pneumonic areas were found in the lungs.

XXIII.—Until a few years ago, ganglions were commonly believed to be due to synovial fluid from a nearby joint, which had escaped along a tendon. After reviewing the literature of the subject, Borchardt reports the case of a Russian dentist, with a firm, spindle-shaped tumor, 6 cm. long, on the inner side of her arm. The skin was not adherent over it. As it was increasing in size, she had it excised. On incision, a bluish cyst was found in the tendon of the long head of the triceps, containing a mass of jelly. It was a typical ganglion, both macroscopically and microscopically, characterized by a specific, widespread degeneration of the connective tissue, leading to the cyst formation. Its etiology was unknown. Only two analogous cases have been found in literature. They are quoted. From the minute study of these cases, Borchardt concludes that a ganglion can be compared with other softening cysts. He believes that most ganglions are par-articular, a true arthrogenous ganglion being very rare. The case above described is an example of a tendogenous ganglion, due to degeneration of the tendon; while those

ganglions which follow softening in the periosteum should be called periosteal ganglions. [M. O.]

XXIV.—Young reports the case of a man of 48, who had his right testicle removed nine months ago for tuberculosis. Since then he has had great pain at the end of urination, with an evening elevation of temperature. The urine contained tubercle bacilli. From a cystoscopic examination, under chloroform, the posterior wall at the upper end of the bladder seemed diseased. There were hard nodular masses about the right seminal vesicle and vas deferens. Suprapubic cystotomy was performed, and another cystoscopic examination was then made. The vertex and posterior wall of the bladder were found affected. The peritoneum was stripped from the bladder and rectum, and the seminal vesicles and vasa deferentia excised. Then the upper, posterior part of the bladder was excised, and the bladder closed, a catheter being left in the urethra, with drainage through the suprapubic wound. He recovered very slowly. The second case was in a man of 62, in whom the same operation was performed, with the excision, also, of the upper part of the prostate, and of both testicles. A tubercular ulcer in the bladder was also removed. He is now recovering nicely. Young describes the technique of the operations in full. [M. O.]

XXV.—Lennander reports the case of a woman, aged 29, from whose right kidney a swelling had been growing for 8 years. Six years ago she had an attack of pain and tenderness over the tumor, with fever, all of which symptoms disappeared suddenly, with the appearance of pus and blood in the urine. The tumor did not diminish appreciably in size. Percussion over the large tumor now elicited absolute flatness, and causes the patient much pain. On opening the abdomen, it was seen that the tumor had pushed up the peritoneum before it, and on incision, at first a clear fluid escaped, which later became thick and purulent. As the patient's general condition was very poor, the pyonephrotic sac was stitched to the abdominal wall, and packed. The tumor was no longer palpable, region of the kidney was tender, yet the patient's general condition was very poor. From the pus, a pure culture of the bacterium *coli commune* was obtained. Ten days later, acute appendicitis occurred, lasting about 5 days. Two months later, as the fistula had not healed, Lennander operated again, removing the appendix, and the pyonephrotic sac, after which he performed nephropexy upon the rest of the right kidney in which one pelvis was still sound. The kidney had a double pelvis and two ureters, and had probably been movable for at least 8 years. This might have caused pyonephrosis. In two months the patient was well. Lennander quotes three similar cases already reported, and then adds a description of a preparation, from a boy of 6, in whom the left kidney had a double pelvis and two ureters. In this case pyonephrosis had followed cystitis from phimosis. [M. O.]

XXVI.—While osteomyelitis is primarily a disease of childhood and youth, it sometimes occurs also after the age of 25 years. The oldest patient among the cases Reiss reports was aged 54. Occasionally a healed osteomyelitis will break out again years later. Following the infectious diseases, osteomyelitis may occur at the site of a former fracture, rheumatism, or bone disease. Osteomyelitis generally occurs in the diaphysis of the long bones, near the epiphyseal junction. Suppuration leads down to marrow, and necrosis follows. Lengthening often follows necrosis. Fracture may occur spontaneously. The result of these processes depends upon the cartilage groove; when this remains intact, growth continues; if this be destroyed, even partially, shortening will result, and no epiphyseal line will be seen in Roentgen photographs. Reiss reports, in all, 16 cases of osteomyelitis, with discussion of their course and main complication, disease of the neighboring joint. He concludes that when the cartilage groove is partially destroyed, recovery, with normal growth following, is possible; but that in most cases, even when a part of the cartilage groove is macroscopically normal, bony callus will take its place; that after separation of the epiphysis, in osteomyelitis of the epiphysis, no regeneration of the epiphyseal cartilage can occur, since bony callus holds them together; that when osteomyelitis occurs primarily in the epiphysis, it in no way affects normal growth; and that should this process extend from the epiphysis to the diaphysis, thus destroying the cartilage groove, further growth will stop. The article is well illustrated with Roentgen photographs. [M. O.]

XXVII.—Fenger reviews the literature of the renal retention, dividing the cases into those in which the site of obstruction is in the kidney itself, in the pelvis of the kidney or outlet of the ureter, and in the ureter itself. A table of 30 cases collected follows, 10 of which Fenger had himself. The extra-pelvic operation gives the best results. But when a large cystonephrotic sac exists, the trans-pelvic method must be followed. There is little danger to life in these operations. In 5 cases the result was negative, nephrectomy following in four of them. Good functional results were obtained in 22 of the cases. In a few of these, fistulae remained. Only two of the cases have recurred, in both of which nephrectomy was necessary. [M. O.]

XXVIII.—Schmieden studied 49 cases in which "joint-bodies" occurred, and removed all but 5 of them by operation. He considers only cartilaginous or bony bodies true joint-bodies, excluding foreign bodies, blood-clots, tumors, etc. They frequently follow traumatism, especially in tubercular subjects. A few showed connection with the interarticular cartilage. One was found outside of the joint-capsule. These true joint-bodies are composed of connective tissue, cartilage, and bone, being broken off bits of the bones which enter into the formation of the joint. They may in fact increase in size, being set free in the joint. Schmieden divides them into those caused by arthritis deformans, which are not microscopically part of the normal joint surfaces, and those not due to arthritis deformans, which contain parts of normal joints. Nine cases were due to arthritis deformans. Those not caused by arthritis deformans may be traumatic. Fourteen cases were due to direct traumatism, 6 cases to indirect traumatism. In three cases the joint-bodies certainly contained part of the joint surfaces, yet no traumatism or inflammation had ever effected the joint. Perhaps a slight, hardly noticeable traumatism, in childhood, might have caused these joint bodies. In simple cases, the joint-bodies can be removed. In severe cases, resection of the joint will be necessary. [M. O.]

XXIX.—Marx and Woithe believe that all methods in use for ascertaining the virulence of bacteria are faulty. Neither animal inoculation nor serum reactions have overcome these faults. They estimate the functional worth, i. e., the virulence, of a pathogenic micro-organism, not from its effect upon any animal, under unknown conditions (immunity, or disposition), but from certain morphologic peculiarities of the bacterial cells, which stand in the closest relation to the creation of specific functions (chemical, biological, etc.), easily and surely recognizable microscopically, with judicious handling of material. Their process, which depends upon the formation of "Babes-Ernst" metachromatic bodies when the bacteria have reached the point of greatest virulence, passes through four stages of morphologic differentiation. To do this successfully, the following technical points must be carefully carried out. No water must be allowed on the cover-glass; the culture material must be thickly spread; it must be well dried and fixed; it must be cooled before adding the methylen-blue; and it must be examined microscopically at once. Their method is for bacteria without spores, which do not belong to the tuberculosis group. To ascertain the grade of virulence of pathogenic bacteria found in a body, the bacteria must be examined directly with the body juices in which they were found. For cultures will not show how virulent the fresh micro-organism was. They have experimented mainly with staphylococci. After the virulence has been discovered, inoculation in animals will show its pathogenicity. [M. O.]

XXX.—Schaefer gives a detailed history of the lance as an implement of war, with an account of the character of the wounds caused by it in the different parts of the human body. He concludes that from statistics of military surgery, lance wounds, in the overwhelming majority of cases, have been slight. The literature shows a series of severe lance wounds which have run a surprisingly favorable course. This is due to the shape of the lance, as its blunt, swollen point pushes the organs out of the way. Therefore it is a humane implement. Finally, by making its point sharper, it would become a very dangerous weapon. [M. O.]

31.—In those cases of narrow stricture, situated low down in the esophagus, in which gastrostomy must be performed, much depends upon whether even a small instrument will then pass through the stricture. If this first effort meet with success, all will probably go well. Alapy reports the case of a boy of 7, with two strictures of the esophagus following the ingestion of lye. The upper stricture could be passed, but the lower, just above the cardia, would not let even a filiform bougie by. Gastrostomy was performed. A week later, an elastic bougie was introduced through the stomach up to the site of the stricture, and a silk catheter was passed over it. Then the bougie was withdrawn, and a filiform inserted, which easily passed through the stricture and out to the mouth. After that, dilatation was accomplished quickly, and the child recovered. Alapy devised this method to overcome two difficulties: Finding the cardia, and passing the stricture. As ordinary filiform bougies are not long enough, he advises the use of the Phillips bougies. [M. O.]

32.—Franke divides his researches in the treatment of complicated fractures into two parts, those of the extremities, and those of the skull. Modern aseptic treatment has made these wounds much less dangerous than they formerly were. In every case he tried to keep the wound aseptic, to put the fragments in good position, to keep up absolute rest, followed, after healing, by regulated movements. The region of the wound was disinfected, and if the wound was small, and contained a foreign body, it was removed, the wound dried out with sterile gauze, and a sterile dressing applied. In large wounds, counterincisions, drainage, removal of splinters of bone, etc., followed, but washing out with antiseptics was never done. Large pieces of bone were saved, sharp edges being sawed off first, to prevent pressure on the blood vessels, and gangrene. When dislocation seemed imminent, bones were sutured together with silver wire. Attempts were made to cover the bone with soft parts. The injection of a little iodoform ether, and drying with sterile gauze, completed the treatment. With this many limbs escaped amputation. Even when gangrene was feared, conservative treatment was carried out. Yet some cases had to be amputated. Immobilization was secured by plaster bandages, extension, or splints. Roentgen photographs were taken regularly. The fractures of the skull were treated in the same way. Wounds were generally enlarged, to see the amount of damage done. Even a greater attempt was made here, to make the surface smooth. Many blood vessels of the dura and pia were ligated. Where parts of the brain were badly injured, they were removed, as were foreign bodies, splinters, etc. If possible, clefts in the dura were sutured. Great care was taken to prevent bone defects. The bone was replaced, after being washed in a boric acid solution, and the skin closed over it. Osteoplastic resection was necessary in some cases. The histories of 73 complicated fractures of the extremities, and of 24 complicated fractures of the skull are given in detail. [M. O.]

33.—Wolff reports the rare case of a carcinoma occurring in the wall of a closed dermoid cyst. He could find no similar case in literature. A Russian, aged 21, had always had a small tumor over the inner canthus of his left eye. This had increased in size during the past two years, but never caused any symptoms. It was elastic, but did not decrease on pressure. A typical dermoid cyst was removed with difficulty, on account of its attachment to the periosteum. Some of the surrounding connective tissue was removed with it. Microscopical examination showed carcinomatous degeneration of the cyst wall. He reports a similar case following the removal of a dermoid cyst of the sacrum. In both cases carcinomatous changes occurred in dermoid cysts, in one, closed and intact, in the other, upon the remaining wall left after excision of the cyst. [M. O.]

34.—Kelling speaks of the prejudices against the use of the Murphy button in gastro-entero-anastomosis. Yet he considers that a good anastomosis button will resemble the Murphy button, for it must remain unchanged until the

necrotic intestinal wall has been thrown off, and then be wholly digested in the stomach or intestines. Kelling has constructed a button from ivory that has been deprived of its calcium. It is in one piece, a cylinder with funnel-shaped ends, covered with rubber as a protection against the digestive juices. This covering is absent in the deep outside groove where the stitches will be placed. It is fixed in place by two sutures. Its application is fully described, with attention to every detail. A number of experiments upon animals follow to show its usefulness. For operations on the colon. Kelling has devised a wooden button, which he has used in dogs. Kelling has also employed absorbable plates of bone or ivory from which the calcium has been removed. [M. O.]

35.—Hugel reports three cases of colon tuberculosis in which operation was necessary. In the first the mass was in the ileocecal region; in the second, in the ileocecal region, ascending and transverse colon; and in the third, in the right colic flexure. Resection of the affected part of the intestine, with anastomosis, was performed. Two of the patients recovered while the other died. Microscopic examination confirmed the diagnosis of all three cases. Hugel believes that the whole part affected should be removed. Should phthisis also exist, he thinks that the intestine should be stripped for its entire length, and the exposed ends of the intestine opened. With an iodoform gauze compress the stripped intestine can be cut off from the peritoneum, and resection can be formed later, when the strength of the patient permits, without a second laparotomy. But he believes that by lighting off the mesenteric vessels leading to the exposed section of the intestine, certain involution of the tubercular process will follow, and perhaps save later resection. [M. O.]

36.—Grosse reports the case of a girl of 5, whose right leg, especially below the knee, was markedly smaller than the left, even at birth. Nor did the right leg grow below the knee. Various different supports had been used without effect. Roentgen photographs showed the absence of the tibia, the fibula being alone. Professor von Bramann operated, bringing the fibula into the knee joint, taking great care that the epiphyseal cartilage was not injured. Foot and leg were then put in plaster. With a support down the leg, about the waist, and a block under the foot, she soon could run. In six weeks femur and fibula had grown together, and her leg has developed well in the two and a half years since. The former shortening of 5½ cm. has been decreased 2 cm. She can now support herself without any splint, walking with a slight limp. Grosse reports another case of von Bramann's, with similar results, no splint now being needed. M. O.

37. Manasse reviews the experimental operations upon nerves, before telling of his work in grafting one nerve upon the other. For a successful result, in investigations of this kind, he believes that function must be restored throughout the region supplied by the paralyzed nerve, the peripheral end of which has been grafted upon a neighboring nerve; that electric excitability must return; that the two nerves must grow together anatomically, which will be seen, histologically, by the continuity of the nerve-fibres. On account of its simplicity, Manasse decided to graft the facial nerve upon the accessories, as treatment for traumatic paralysis of the facial nerve. He performed experiments upon 11 dogs 5 of which were carried to a conclusion. Their histories follow in detail. A description of the different methods of operating is given. Manasse's results were not at all satisfactory, nor does he consider the operation an easy one. [M. O.]

23.—During 10 years' experience, von Bokay has intubated 1203 times. He divides the injuries from intubation into those occurring during intubation; those occurring while the tube remains in the larynx; those occurring during extubation; and those occurring later, cicatricial stricture, stenosis, etc. During intubation the mucous membrane is apt to be scraped off, or false passages may be made. Both occur as a rule above the vocal cleft, and it may be possible to fracture the cricoid cartilage. The slight abrasions of the mucous membrane occur often, and heal rapidly. The histories of 5 cases of false passages are given, with photographs from the autopsies. The diagnosis is easily made, for the symptoms do not ameliorate, and hemorrhage may occur following intubation. The prognosis is unfavorable. Von Bokay thinks that these accidents are due mainly to unskilled intubation. Tracheotomy will often be necessary, yet life may not even then be saved. While the tube is in place, ulcers can easily form. The mucous membrane becomes irritated by the pressure of the tube, inflammation follows, and the cartilage is laid bare 72 hours after intubation. Such ulceration was found in 13% of von Bokay's cases at autopsy. In 5% only were deep ulcers seen. In his experience, the ulcers were seen on the anterior wall of the larynx, trachea, thyroid and cricoid cartilages. Experiments show that ulceration is not due to frequent intubation, but to tubes that have been left in place some time. Sixteen cases of ulceration, out of 1203 cases, healed after tracheotomy. Most ulcers occurred in the first and second year; a tube was perhaps used that did not suit the child; or the diphtheritic process may itself have caused ulceration. The histories of 18 such cases follow. Expectoration will be blood-streaked, the ulcer is sensitive to pressure, a dark spot will be noted upon the tube, or laryngeal examination may locate the ulcer. When the ulcers are slight and superficial, they will heal easily. The use of well-modeled and well-graduated tubes correctly put in place, left there as short a time as possible, with serum given, will prevent, as far as possible, the occurrence of deep ulceration in cases intubated. Tracheotomy is only indicated when the presence of a deep ulcer is positively known. The danger of injury during extubation is least when the tube is extracted by the thread or by hand; while it is most possible when instruments are used for extraction. Slight abrasions heal easily, but hemorrhage may occur. Some degree of hoarseness results. If this persists over a week after the removal of the tube, post-diphtheritic paralysis has occurred. It is but seldom that cicatricial stricture, stenosis, or atresia of the larynx follows intubation, and then only in cases of laryngeal diphtheria. It has always occurred in children under six years of age. The histories of two cases of stricture with stenosis, and three cases of atresia follow. Renewed dyspnea, a hindrance to, or the impossibility of withdrawing or introducing the tube, with laryngoscopic examination, will show a stricture. The prognosis is favorable for permeable strictures, but not for complete atresia. Slow healing about a properly fitting tube is the best method of treatment for these cases. The treatment will be incision of the cicatrix, followed by methodic intubation; widening by bougies; transplantation of epithelium; or resection of the scar completely, followed by suturing the ends of the respiratory passages together. Methodic intubation has been most successfully performed, in four out of six cases; neither the use of the bougies nor the transplantation of epithelium has been a success. The one operated case, complete resection of the cicatrix with the ends of the larynx and trachea sutured afterward, has been wholly cured. Thus methodic intubation should always be attempted, the more severe operations being left as the last resort. [M. O.]

24.—Wulff reports two cases of spontaneous gangrene. The first patient, a Pole, aged 38, had noted pain, with feelings of cold and "pins and needles" in his left leg for three years. Two years ago, an ulcer appeared on the inner side of the leg. Though syphilis was denied, anti-syphilitic treatment somewhat improved the condition, but not the ulcer. The pulse was still felt under Poupart's ligament, but not in the popliteal space. The next year his condition grew worse, and the ulcer increased in size, with widespread necrosis of the tibia. The entire bone grew cold, and the pain excruciating. There was no longer any pulsa-

tion palpable at Poupart's ligament. The leg was disarticulated at the knee, since which operation some necrosis of the skin of the inner flap has persisted. The arteries in the leg were found with a very narrow lumen and thick walls, easily distinguished from the veins macroscopically. Thrombi existed in the veins, but not in the arteries. The nerves were normal. The other patient was also a Pole, aged 28. He had never contracted syphilis. Pain first appeared in the left leg four years ago, upon walking for a long time. He was treated for rheumatism until gangrene of the little toe developed, a year later. First the foot, then the thigh, was amputated, with quick recovery following. Two years later the same condition began in the right foot. As in the former case, the heart and kidneys were normal. The toes were black, the rest of the foot cold and pale. A Pirogoff amputation was done, but the flaps became necrotic. Resection of the tibia was necessary, followed later by disarticulation at the knee, since which proceeding, he has kept well. Here, also, the nerves were found normal and the arteries and veins very small. After a full review of the literature, Wulff, who observed five cases, considers it a general dyscrasia, often found in the people of Poland, generally in men free from lues, diabetes, or nephritis, but who smoke 30 cigarettes or more daily. He concludes that the process is probably a primary endarteritis with secondary thrombosis, due to an abnormal vasomotor contraction, analogous to Raynaud's disease. [M. O.]

25.—Helbing divides the fracture of the calcaneum into those which are broken apart, leaving a cleft between the fragments, and those which are crushed into pieces. He discusses the former variety only, and reports the case of a woman of 57, who, on putting her foot backward while standing upon a chair, came down heavily, her foot striking the floor. There was great pain, yet she has been able to walk since. There was slight foot-drop, with a large tumor above the insertion of the tendo-Achilles. Below this a straight furrow was noticeable. A Roentgen photograph showed that the calcaneum had been fractured, the upper fragment being pulled up by the tendo-Achilles, which, with some exudate, caused the tumor. The furrow below it showed the cleft of the fracture. She was well in four weeks. But on being examined six months later, the upper fragment had again risen, from the tension of the tendo-Achilles, without causing any pain. Helbing concludes that this fracture is not like the ordinary fractures of the calcaneum in which the cleft is vertical; that the prognosis of this sort of fracture is very unfavorable; and that while the ordinary vertical fracture is due to a fall from a height of two meters or more, this results from a fall of one meter or less. The cause of the fracture, the power of the tendo-Achilles, is also the cause of the unfavorable result. [M. O.]

26.—In 1807 Bozzini first attempted esophagoscopy. But not until Kuessmaul, in 1868 was any practical method of esophagoscopy or gastroscopy discovered. In this, Kuessmaul followed the "sword-swallower" idea. Then came the Desormeaux endoscope, in 1853. Killian describes the many methods invented, many of them practically useless, with a detailed review of the subject. [M. O.]

27.—When appendicitis is protracted, a fecal fistula often results. Rose reports three fatal cases of perforation of the cecum following appendicitis. In the first case fecal matter escaped and formed a circumscribed peritoneal abscess, between the folds of the small intestine. In the other two cases, perforation occurred in the cecum, circumscribed abscesses being also found. The autopsy reports are given. Rose advances four theories to account for the occurrence of the rectal fistulae in appendicitis, (1) from injuries during operation; (2) softening of the intestinal walls from long standing disease, old age, etc.; (3) a stitch abscess following operation; and (4) secondary inflammation of the cecum. A fistula generally arises in the small intestine, from perforation of the cecum with or without operation, following atrophy or ulceration of the intestinal walls from the pressure of a quantity of pus. Secondary inflammation of the cecum with fistulae, adhesions, and much lymph formation needs speedy operation. Should fecal matter appear in the wound after operation, it will be due to perforation probably from the long pressure of an abscess. A case of true appendicular fistula is described, which was cured by removing the appendix. The histories of 10 other cases follow, with rectal fistula, artificial anus, peritonitis, empyema, urinary fistula is described, which was cured by removing the appendix. The histories of 10 other cases follow, with fecal fistula, arti-

ficial anus, peritonitis, empyema, urinary fistula, etc. When appendicitis is protracted, the mesenteric glands will swell, and peritonitis may follow. But the main danger in this form of appendicitis is that fecal matter may enter the peritoneum, to prevent which, an early laparotomy will be necessary. If the appendicitis has lasted over two weeks, laparotomy should be done at once. If an abscess, or free pus is found, it will be better to leave in drainage than to close the wound again. [M. O.]

23.—Schmidt reports the case of a girl of 13, who knocked her right internal malleolus. An abscess followed, which was incised. She then complained of stiff neck, with tenderness along the cervical vertebrae. Paralysis of the right arm occurred suddenly, followed by paralysis of the three remaining extremities. Then pain appeared in both legs. Next involuntary evacuation of bladder and rectum was noted. On operating, an abscess was found in the cervical vertebrae, from which a large quantity of pus flowed. The left arm and leg improved at once, and the pain disappeared. Next the left hip became affected, but recovered without forming another abscess. Both malleolar and cervical wounds healed. Her neck can now be moved well. The left arm recovered rapidly, the right very slowly. Schmidt calls it an undoubted case of outspoken multiple osteomyelitis, affecting the right ankle, cervical vertebrae, and the left hip in turn. He discusses in full the nervous symptoms from the pressure of the pus contained in the cervical abscess, and quotes 16 more cases of osteomyelitis of the vertebrae. [M. O.]

29.—Lanz reports a rare case of leontiasis with generalized fibroma molluscum, in a man of 55. His left eye was always larger than the right. At the age of 9, his left upper eyelid began to swell, increasing in size gradually. At 20, it so deformed his face as to prevent all idea of military service. He believes that the left eye was already blind at 9 years, when the skin eruption first appeared. There has never been any pain. Over the left side of the face hangs a huge sac of skin, rising from the nose and forehead, extending to the left angle of the mouth. It hangs in five folds, and is well shown in the photographs accompanying the article. There is very little hair on the mass, in which an empty cavity is seen for the left eye, the lids swollen and edematous, the eyeball invisible. The left eyebrow and lashes are absent. When he closes his eye forcibly, the mass rises 2 cm. Over the entire body is a widespread fibroma molluscum. He will not permit any surgical interference, unfortunately. [M. O.]

30.—Pupovac reports a rare case of sarcoma of the penis, occurring in a man aged 47 years. A swelling on the right side of the penis was first noticed 6 months before admission to the hospital. This gradually increased in size in spite of potassium iodide administered internally and externally. Otherwise he was perfectly healthy. The inguinal glands swelled gradually. Sarcoma was diagnosed, and the penis amputated. The inguinal, iliac, and abdominal lymph glands, along the descending aorta, were found affected and were extirpated. Two days later he died with diffuse peritonitis. The tumor was a round celled sarcoma of the corpora cavernosa, with metastasis of the lymph glands. The urethra and the blood vessels were not affected. [M. O.]

31.—The great rarity of isolated fractures of the lesser tuberosity of the humerus caused Lorenz to report this case. A man aged 45, was struck by a falling marble pillar, which, striking his hand, rolled his right arm outward forcibly, causing great pain in the shoulder. After the swelling disappeared, he was able to use the arm. It could be rotated outward to an abnormal extent. On palpation a jagged surface was felt in the place of the lesser tuberosity. This is tender, and crepitus is audible on rotating the arm. The arm cannot be rotated inwardly at all. A review of the literature follows, with the quotation of a few cases. It is probably caused by forcible contraction of the subscapularis muscle. The treatment should consist in incision with suturing or nailing the fragment into place. His patient would not permit operation. [M. O.]

32.—While the diagnosis of malignant tumors of the rectum is not as a rule difficult, it is impossible to find the cause of some cases of hemorrhagic proctitis. Stierlin reports such a case in a man of 40. For four years he has lost blood, off and on, when his bowels moved. This often was lost in quantities, with attacks of diarrhea. He was treated for hemorrhoids for three years. On admission to the hospital, he was having 5 to 6 bowel movements

daily, mixed with bright red blood. He was very thirsty and weak. The mucous membrane was easily injured, followed by bleeding. Otherwise the rectum was normal. The sphincter was dilated, the entire mucous membrane being found a mass of soft folds, like a bloody sponge. There were no hemorrhoids, ulcers, or tumors. After three weeks' treatment with bismuth, tannic acid, etc., he began to improve, and recovered. Other cases are quoted from the literature. The cause of the hemorrhage is unknown. The diagnosis of hemorrhagic proctitis is made only by inspection. [M. O.]

CENTRALBLATT FUER GYNECOLOGIE.

January 12, 1901. No. 2.

1. Discussion on Gersuny's Method of Paraffine-Injection in Incontinence of Urine. JOHANNES PFANNENSTIEL.
2. On Subcutaneous Division of the Sphincter in Restoration of the Peritoneum. HEINRICH FRITSCH.
3. A Case of Uterine Myoma Complicated by Diabetes. DR. JAHREISS.

1.—Pfannenstiel, in writing on the question of Gersuny's method of injections of paraffine in incontinence of urine, reports the following case: A woman, 39 years old, with a strong constitution and free from organic disease, suffered from incontinence following extirpation of the urethra for carcinoma of the uterus which had involved the vaginal walls. The entire urethral canal had to be extirpated together with the connective tissue up to the pubic arch. A fistulous tract admitting of the index finger resulted, and in order to cure this it was resolved to practice injections of paraffine ointment as recommended by Gersuny. By means of a sharp pointed canula an injection into the connective tissue of the vaginal submucosa was made. The patient stood the operation well, but shortly after the injection suffered from nausea, chills, severe headache, shortness of breath and dyspnea. The respirations reached 36 per minute. Examination of the lungs showed no pathologic condition, but on the following day the patient complained of pain in the left side. The respirations had increased to 40 per minute, and there was a slight cyanosis of the face. The temperature was 39 degrees C. and the pulse 104. Still there were no objective signs to be found on examination of the lungs. On the following day examination showed some consolidation of the lung on the left side, and a diagnosis was made of a paraffine embolus into the lung. After a slightly prolonged convalescence the patient made a good recovery. Pfannenstiel speaks of the possibility of lung-embolism and also of embolism of the brain as sequelae of this method of treatment. [W. A. N. D.]

2.—Fritsch remarks that in performing perineorrhaphy there are two important principles to observe: 1. To cut nothing away, to sacrifice no tissue, and not in the old sense to freshen the edges, but merely to split the tissues, restore the old relations, and then to suture together the perineum; and secondly, to recognize the value of the function of the sphincter. After the operation has been performed, however, in this manner in certain cases the sphincter is so tight that the introduction of the finger into the anus is almost impossible. The tension is so strong that flatus can hardly escape, and as a result there not infrequently follows a distension of the ampulla of the rectum in which there accumulates both gas and fecal matter. To overcome this condition Simon suggested subcutaneous division of the sphincter. This can be accomplished, the finger in the rectum, by means of a sharp tenotome, the action of the knife being controlled by the finger in the rectum. It is best to make two incisions, one to the right, the other to the left about one-and-one-half cm apart. The small incisions may then be closed by means of iodoform-gauze. Fritsch has also employed a sagittal incision whereby the hemorrhage is not so severe and healing is just as sure, although the pain is more severe than by the subcutaneous division. The after-results of the subcutaneous division of the sphincter are so good that he is inclined hereafter to employ this method as a regular procedure. [W. A. N. D.]

3.—Jahreiss, of Augsburg, reports an interesting case of uterine myoma, complicated by diabetes, the patient being a woman 48 years of age who had for four years suffered from severe menorrhagia and for one month had complained of a severe thirst, together with pallor of the heart and slight swelling of the feet. Examination showed her to be somewhat anemic, and there was a certain amount

of lividity of the mucous membranes. The pulse was frequent, small and irregular, and both feet up to the ankles were edematous. The uterus presented a myomatous tumor which reached up to the umbilicus. The urine was quite sugary. On account of the marked anemia and the irregularity of the heart, operative interference for the relief of the myoma seemed contraindicated. Instead the patient was placed in absolute rest in bed and administered iron and tonics. After four weeks the general condition was better and the pulse was less frequent. There was but slight change, however, in the amount of sugar in the urine. The patient ultimately suffered from neuralgic attacks, especially in the right iliac fossa. The constituents of the urine remained the same until the death of the woman. The etiology of the diabetes is not plain; there was no hereditary history, nor was there the history of syphilis; the nervous system was also intact. The cause might have been found in the excessive hemorrhage. [W. A. N. D.]

January 19, 1901.

1. Gynecological Massage. R. OLSHAUSEN.
2. A Case of Extensive Radical Operation for Pregnancy Complicated by Uterine Cancer. TH. MICHO-
LITSCH.

1.—In discussing the question of gynecological massage Olshausen concludes as follows: Pelvic massage is of value in cellular-tissue exudates which show a tendency to become torpid and in all inflammatory conditions which persist for a long time. Also in all cases of exudate which can be grasped by the external hand and compressed between the fingers of this hand and that introduced through the pelvis. Only such tubal tumors as are high up in the pelvis are open to this method of treatment, as hydrosalpinx in which the fluid accumulations can be caused to escape through the uterine canal. In tubes with thickened wall, but without fluid contents, massage may be employed to favor removal of the infiltration. Peritoneal adhesions, hematoceles, and anomalies of position of the vagina and uterus are not suitable for massage unless accompanied by exudates which are the direct cause of the displacement: the massage then, by removing the exudate, will improve the local condition. [W. A. N. D.]

2.—Micholitsch states that the question arises as to what is the proper treatment for carcinoma of the uterus in pregnancy, whether by vaginal or abdominal operation. He reports a case of radical operation performed upon a woman in the eighth month of her pregnancy. The history of the case is as follows: The patient, a woman 41 years of age, was in her tenth pregnancy, and advanced to the eighth month. For three months she had suffered from irregular hemorrhages. Examination showed her to be somewhat cachectic with wasting of the panniculus adiposus. She was in a generally run down condition, and over both lungs there were marked bronchitis rales. The fundus of the uterus reached to the xiphoid cartilage. The fetal heart-sounds could be plainly detected. On the anterior cervical lip was found a small circumscribed cancerous ulcer of the size of a walnut. The vaginal mucous membrane was intact; the parametrium was free, and it was impossible to find any large lymph-glands. The operation on the following day consisted in a median Cesarean section, removal of the child, the introduction of a gauze-tampon into the uterine cavity and closure of the uterine wound by deep sutures. The ureters were difficult to locate on account of the enlargement of the parts, but they were finally freed from their relations to the uterus, as was also the bladder. The round ligaments, the infundibulo-pelvic ligaments, and the sacro-uterine ligaments were ligated and divided. An examination was then made for infiltrated glands with the object of their removal, should they be found. The vaginal wall was divided 4 cm. below the portio vaginalis, and iodoform gauze drainage was established through the vagina. The peritoneum was sutured above the gauze drainage and the abdominal wound closed in two layers. The duration of the operation was one hour. The child was a male, 44 cm. long and weighing 2250 drams. The patient made an uninterrupted recovery. [W. A. N. D.]

January 26, 1901.

1. Information Concerning the Traces of the Volsellum Forceps in the Cervix Uteri. R. CHROBAK.
2. On the Suprasmphyseal Cross-section after Kuester. F. KUEHNE.

2. Puerperal Gangrene of the Lower Extremities. E. WORMSER.

1. Chrobak has made an interesting study as to the amount of injury caused by volsellum forceps in the cervix uteri and also the length of time that the traces of these forceps remain in the uterine tissue. His attention was first called to this subject by a case of uterine rupture, the tear lying near the fundus, the question arising as to whether there was any relationship between the uterine tear and the use of the instruments. He has been assisted in his labors by Peham, who gathered statistics for him. He has been able to find 20 cases of abortion in which the cervix was grasped by the forceps, in all of which slight cervical lacerations existed, the result of traction by the forceps. He found that in most of the cases within five days no sign of the teeth of the forceps could be detected. This rapid disappearance was due to the quick regeneration of the epithelial tissue which is peculiar to the puerperal uterus [W. A. N. D.]

2.—Kuehne saw the first case of cross abdominal incision performed by his chief, Kuester, in 1896. Ahfeld also shortly afterwards performed the operation in suitable cases, and Frantzen in 1897 slightly modified Kuester's operation and employed it for ventral fixation of the uterus for the cure of the prolapse. Kahn and others followed in their footsteps. Mikucki has employed the Kuester incision twice, once in a case of ovariectomy and once in ventral fixation for complete prolapse, with falling of the anterior vaginal wall. Pfannenstiel more recently has modified the method so that he not only incises the skin transversely, but also the fascia, and then opens the peritoneum through an incision lengthwise between the recti muscles. He has done this in order to avoid the subsequent development of hernia. He employed this incision in 51 cases. Kuehne reports 12 cases in his clinic operated upon by this method for retroflexion and slight vaginal prolapse. In five of the cases the operation was performed for movable retroflexion, in one of which there was also a prolapse of the anterior wall. The other cases include the following: One case of prolapse with hypertrophy of the anterior cervical lip, one of complete prolapse with falling of the anterior vaginal wall, the uterus lying in the middle position, and five cases of complete procidentia. In the first case there was also performed for the correction of the uterine prolapse an anterior kolporrhaphy; twice was a one-sided salpingo-oophorectomy performed. The ligament was also fastened to the abdominal wall. The indications for the operation are certain conditions of the uterine displacement, tubal pregnancy, small sized uterine myomata, and for the performance of ventral fixation. The contraindications of the transverse incision are large solid ovarian tumors, or those which require total extirpation of the uterine appendage. [W. A. N. D.]

3.—Wormser refers to the article by Burckhard in No. 51, 1900, of this journal, in which he reported two cases of gangrene of the lower extremities occurring during the puerperium. Miller also quotes a case of this complication occurring in the practice of Duflocq, the patient being a woman 38 years old, in her fifth pregnancy, who at the end of the pregnancy suddenly experienced severe pains in the right foot with anesthesia of the part. In spite of this condition a normal birth followed. Four weeks after the labor the foot presented the appearance of marked gangrene with a well-defined line of demarcation. Glycosuria ensued and the patient died on the 29th day after the disease manifested itself. Autopsy showed a slight thickening of the mitral valve with a thrombosis of the right femoral artery. Another case, according to Wormser, is reported by J. B. Swayne of a woman 34 years of age in her first pregnancy. She likewise suffered from pain in the right leg followed by the development of a gangrenous spot in the foot and ankle, which also necessitated operation. Section showed a slight thrombosis in the muscular veins, but no thrombosis in the larger veins. [W. A. N. D.]

CENTRALBLATT FUER CHIRURGIE.

January 5, 1901. (28 Jahrgang, No. 1.)

1. The Treatment of the Shortening in Fractures of Both Bones of the Leg. N. KAEFER.
2. The Treatment of the Fractures of the Patella. ALEX. WIENER.

1.—When both bones of the leg are broken, some shortening follows. The fractured bones should be reduced, un-

der anesthesia, placed in a plaster of Paris bandage, and left 8 to 10 days. Weight extension seems of doubtful benefit in treating these fractures. Von Eiselsberg used elastic traction in the plaster bandage. Kaefer has made an **apparatus**, with screws, which is fitted into the plaster bandages at some little distance from the site of the fracture. Some space is left between the upper and lower bandages, only bridged over by the screws of the apparatus. By taking in a half screw daily, this distance is increased, and shortening is thus prevented. Kaefer reports a case treated in this manner with excellent result. [M. O.]

2.—**Fractures of the patella** only heal with difficulty. The ideal treatment, cutting down upon the fragments, suturing them together, and then closing the incision, is attended with great danger of infection, and a few patients will submit to it. Wiener treats them by wrapping the knee in **elastic bandages**, over much wadding, and the patient walks home. This is left on 4 or 5 days. All exudate is then absorbed, and the fragments of the patella are in opposition. The elastic bandages are then replaced, tighter this time. Wiener reports two cases treated thus. Pain is spared the patient and time saved for the surgeon. Wiener believes that fracture of the patella is a new indication for this old treatment. [M. O.]

January 12, 1901. (28 Jahrgang, No. 2.)

1. The Treatment of Luxation of the Peroneus Tendons. H. REERINK.
2. A Simple Method of Plastic Achillotomies. C. BAYER.
3. A New Hand Operating-Table. RATHMANN.

1.—Reerink reports a case of **luxation of the peroneus tendons** of the left foot, upon the external malleolus, with great pain and swelling. There was foot-drop, with adduction of the toes. The foot was placed in a splint, and ice applied. Six days later the tendons were replaced in position, and kept there by strips of zinc oxide adhesive plaster. Four days later a plaster of Paris bandage was applied. Two weeks afterward, this was removed, and another put on for three weeks longer. Then massage was given daily for a few weeks. Since then the foot has been in excellent condition. A Roentgen photograph showed the malleolus intact. Reerink cites the literature of the subject. [M. O.]

2.—Bayer reports a case in which he performed **tenotomy** upon the **tendo Achillis**, dividing the operation into halves. One half of the tendon he slit subcutaneously, in the muscle itself; the other, down near the calcaneum, in the tendo Achillis proper. Thus no scar resulted, and the foot-drop was easily corrected. A week later, on removing the splint, the tenotomy openings had completely healed, and the foot was in normal position. There was no visible difference between the two sides of the divided tendo Achillis. After another week, the patient walked well. [M. O.]

3.—Rathmann describes a **stand** which can be clamped upon any table, to be used for **operations upon the hand**. It is made of glass, held in metal, and can be raised to any height desired. Rathmann advises its use for all operations upon the hand. [M. O.]

January 19, 1901. (28 Jahrgang, No. 3.)

1. How is Regular, Deep, Quiet Breathing Obtained, in Administering Anesthetics? C. HOFMANN.
2. A New Plastic Operation on the Cheek, with Double Flaps. F. NEUGEBAUER.
3. The Sterilization of Silk Catheters. M. W. HERMAN.

1.—It is now generally understood that the best method of administering anesthetics is to allow plenty of air. Holmann believes that **quiet talking**, and **counting aloud** will keep some individuals still while taking an anesthetic. But to make them **begin counting at 200**, and **count backward** will cause them to breathe quietly and regularly. Patients take more easily to this than to ordinary counting. He lets the counting begin a minute before a drop of the anesthetic is used, and then this is added drop by drop, gradually, so that enough air enters the lungs to prevent coughing, etc. Hypodermic injections of $\frac{1}{4}$ to $\frac{1}{2}$ of a grain of morphine, before the anesthetic is given, will also help to cause regular, deep, quiet breathing throughout the entire operation. [M. O.]

2.—Neugebauer operated upon a child, 5 years old, part of whose cheek, near the angle of the mouth, had been

destroyed by **noma**. He employed **Krause's method**, making **two skin flaps**, without pedicles, from the neck. In two weeks the double flaps had grown together, and cicatricial contraction was not noticeable. The results of the Krause double flap method, without pedicles, cannot be distinguished functionally from the operations with pedicled flaps. [M. O.]

3.—While metal catheters are easily sterilized by boiling, the **sterilization of silk catheters** has always been difficult. Hermann has experimented with an **ammonio-sulphuric solution**, concluding that silk catheters become more elastic, and are in no wise harmed by being boiled 5 hours, frequently, in this solution; that very dirty catheters will be sterilized after boiling from 3 to 5 minutes in this solution; that they can be used straight from the solution, without injury to the urethra; and that metal and elastic catheters, sounds, and bougies can be sterilized in this solution also. Herman believes that this is the simplest and best method for sterilizing silk catheters. [M. O.]

January 26, 1901. (28 Jahrgang, No. 4.)

1. Chirol.—R. SCHAEFFER.
2. Two Technical Propositions in Gastro-enteric Surgery. M. SCHMIDT.

1.—In reply to Kossmann's last article defending the use of **chirol** upon the hands in vaginal examinations, (of midwives especially), Schaeffer repeats his objections to chirol, and details six experiments with the bacillus pyocaneus and the bacillus prodigiosus, in all of which the chirol showed its inefficiency. Schaeffer strongly deprecates its use. [M. O.]

2.—Schmidt suggests **gastro-duodenostomy**, after separation of the duodenum from the pylorus, and occlusion of the pylorus. This can take the place of resection of the pylorus, or of gastro-enterostomy, especially when the pylorus is badly affected, and the duodenum is healthy. He also suggests a **plan to avoid the purse-string suture** when using the Murphy button. For this, he advises pushing and rolling the half of the button into place in the intestine, until it reaches the spot where it is wanted. Schmidt would be glad to hear of results of either of these propositions in practice. [M. O.]

February 2, 1901. (28 Jahrgang, No. 5.)

1. A Divided Ureter Treated by Direct Suturing. VON GUBAROFF.
2. The Treatment of Oblique Fractures of Both Bones of the Leg by Bardenheuer's Weight Extension. O. WOLFF.

1.—When it is impossible to stitch the torn end of a **divided ureter** into the bladder, the **two ends can be sutured together**. Von Gubaroff reports an operation for the removal of an enormous fibrosarcoma, during which a bit of the right ureter was carried away. As Van Hook's typical method of joining the ends would have taken too much time, von Gubaroff divided the lower end lengthwise, and invaginated the upper into the lower end, putting in sutures running lengthwise. A sound was first introduced. The technique is shown in several drawings. The operation was quite successful. Laying the ureter free, as was done in this case over 4 cm., seems to have had no bad effect upon recovery. As the patient died a month later, the autopsy showed the **excellent result of operation**. [M. O.]

2.—Wolff, in reply to Kaefer's recent criticism of **Bardenheuer's weight extension** believes that it is only when the technique is faulty that this method of treating **oblique fractures of both bones of the leg** is unsuccessful. He mentions the details of the technique as it should be, the large weight required, (30 to 35 lbs.) and that extension must be constant, day and night. In his experience this treatment has not been followed by shortening. [M. O.]

February 9, 1901. (28 Jahrgang, No. 6.)

1. A Consideration of the Injuries of the Soft Parts and the Origin of the Hemorrhage in Hemarthrosis Genui. C. LAUENSTEIN.
2. A New Procedure in Treating Fractures of the Patella. POPPER.
3. The Treatment and the Prevention of Arthrogenous Contractures in the Knee-joint. C. BURNS.

1.—A **bloody effusion into the knee-joint** is treated in

three different ways: (1) by compression, massage, movements, etc.; (2) absolute rest, with ice, elevation, etc.; and (3) puncture, with rest following the withdrawal of the effusion. The last method has been commonly employed in Hamburg, where Lauenstein operated mainly upon sailors. It removes the effusion more quickly than any other way. Besides, it will permit observation upon the origin of the hemorrhage, especially when the soft parts have been injured. For this, Lauenstein used a long probe, passed through the canula, with which he found injuries of the capsula and ligaments. After cleaning out the joint, it is put at rest with a tight bandage. [M. O.]

2.—Popper has described his method of treating fractures of the patella. He places pieces of adhesive plaster above the upper fragment and below the lower fragment. Then pulls them together, passing one through the other. Another strip of adhesive plaster passes over them. Plaster of Paris bandages are applied below and above the knee, over the ends of the adhesive strips. The next day massage is begun, even while the plaster casts are on. After 2 or 3 weeks, the plaster bandages are removed and massage continued. [M. O.]

3.—Burns reports the case of a girl of 8, with a contracture of her right knee following septic arthritis in infancy. Resection of the knee-joint was performed, but the contracture again appeared. The flexor muscles had contracted, especially the biceps. In another case, a boy with the same contracture following fungus of the knee, the biceps tendons were transplanted into the quadriceps tendons, and left bandaged for three weeks. Since then he walks perfectly. The parents of the little girl would not permit operation. Two more cases were operated upon with excellent results. Resection may become necessary later in some of these cases. But transplantation of the tendons gives good functional results. [M. O.]

February 16, 1901. (28 Jahrgang, No. 7.)

1. An Original Mechanical Treatment for Inguinal and Femoral Hernia. W. WOLFERMANN.

1.—Wolfermann believes that a number of the operations for the radical cure of hernia are performed because of the trouble caused by uncomfortable, incorrectly applied trusses. The pressure of the spring used must not be too great. Constant correctly applied pressure will cause inflammation in the inguinal canal with some adhesion of the opposing walls, and eventual cure of the hernia. Yet the truss should be worn for some months longer. His truss has a long, oval cushion, with its convex surface so applied to the abdominal wall that its highest point covers the abdominal opening of the inguinal canal. Details of the manufacture of his patented truss, of its usefulness, and of how it should be applied, are given, with some of its good results. [M. O.]

March 16, 1901. (28 Jahrgang, No. 11.)

1. An Aid in the Demonstration and Study of Roentgen Negatives. K. LUDKOFF.
2. An Additional Hint in Ether Narcosis. W. REINHARD.
3. Benzin in Surgery. F. FRANKE.

1.—The Roentgen negative has been used for demonstration in Koenigsburg, with the Hirschmann apparatus, a closed box containing an electric light, with the negative fixed before it, in a darkened room. Ludkoff has found that by using an ordinary opera-glass, the details of the negative will come out wonderfully clear. A window may be substituted, though the light will not be as strong. [M. O.]

2. On account of the accumulation of mucus in the throat, so common when ether is employed as an anesthetic, Reinhard uses atropin, with morphin or codein, hypodermically, before operation. Beside drying up the secretion, atropin acts as a stimulant. [M. O.]

3.—As a substitute for ether in removing fat, dirt, adhesive plaster, etc., from the skin before operation, Franke uses benzin. It is cheaper than ether, does not have such a frigid effect, nor does it burn, like ether, upon open wounds. Franke has used benzin for ether for years, since many consider the odor less objectionable than the ether. [M. O.]

March 23, 1901. (28 Jahrgang, No. 12.)

1. The Application of Bandages in Fractures. F. BAEHR.

1.—The main cause of failure to secure union of the

bones after a fracture is the poor or loose application of bandages. Baehr applies pressure by loops about either end, in oblique fractures especially, pulling the two ends into place while the plaster bandages are applied. This secures excellent apposition. Baehr reports two cases treated thus. The loops pull in opposite directions. Both cases healed in three weeks. This simple method is especially serviceable in fractures of both bones of the forearm or leg. [M. O.]

March 29, 1901. (28 Jahrgang, No. 13.)

1. The Technique for Radical Cure of Large Ventral Hernia. SALISTSCHIEFF.

1.—Saltstschiff reports two cases of large ventral hernia in which he operated. The first patient was a man of 30, who, three months before, had cut across his left rectus muscle in the upper abdomen, in an attempt at suicide. This had not been stitched, and a hernia had formed. The sac was replaced in the abdominal cavity, the peritoneum closed, and two flaps cut from the rectus, 8 cm. above and below the cut. These were then turned back and united. Fascia and skin were closed afterward, and he recovered. The second patient was a man of 39, with a hernia through the external oblique muscle. After closing the peritoneum, he cut a long flap from the rectus, and drew it over the opening. This also healed well. No degeneration of the muscle has occurred, and the radical cure in both cases was accomplished. [M. O.]

CENTRALBLATT FUER INNERE MEDIZIN.

February 16, 1901.

Concerning the Demonstration of the Presence of Bilirubin in the Urine by Means of the Ehrlich-Diazo Reaction.

F. PROESCHER.

Proescher has previously reported that he has isolated azobilirubin in chemically pure form. He considers that the diazo reaction is specific for bilirubin, and is extremely delicate. Biliverdin and bilihumin either do not give the reaction or give it in only the slightest degree, and this is even more markedly true of bilifuscin and bilifrasin. The reaction, he states, is an extremely striking color change, and is carried out by saturating 10 c. c. of urine with ammonium sulphate, separating the pigmented precipitate on a small filter, and extracting the pigment with 95 per cent alcohol. The alcoholic extract is acidulated strongly with HCl, and the diazo test, using the ordinary solutions, is carried out. If bilirubin is present the fluid takes a striking blue color. If caustic potash solution is added it becomes red at the neutral point, and when the mixtures becomes alkaline it takes a marked green color. It is best to precipitate with ammonium sulphate and then extract, rather than test the urine directly, as other substances in the urine interfere with the reaction. He states that one can in this way determine the presence of one part of bilirubin in 60,000 parts of fluid. [D. L. E.]

March 16, 1901.

On Reflex Excitation of the Pulse.

M. HEITLER.

Heitler refers to some observations previously reported (which were abstracted in the Philadelphia Medical Journal from the *Wien. Klin. Woch.*, 1899, No. 52). These consisted of a note of increase in the volume of the pulse in a neurasthenic man after percussing the region over the liver and a similar observation when the precordia was percussed. As the pulse grew larger in size the cardiac dulness grew smaller. He has investigated this phenomenon further in a series of persons, chiefly convalescent from slight illnesses, and finds that the phenomenon occurs in the minority of cases only after irritation of the region of the heart and liver; in most cases it occurs after irritation of the heart and liver region, but also after irritation of the skin, the bones, the muscles, the mucous membranes, and the arteries, and after flexing and extending the extremities. Those persons who show the phenomenon after irritation of various regions exhibit a marked variety in the manner in which the phenomenon is produced. With some the reflex is produced only by irritation of the skin in definite regions; in others irritation of the whole skin surface, and in still others by irritation of other tissues, or by irritation of any

of the body tissues. The phenomenon is much more pronounced as a rule after irritation of the sternum than after irritation of the surrounding regions, though the surface over the ribs near the sternum and over the inner end of the clavicles apparently reacts readily, and a particularly irritable region is that over the 5th rib between the parasternal and mammary lines. The reflex after percussion of the liver region is produced only when this percussion is undertaken directly over the liver, not as a result of percussion of surrounding regions. The phenomenon varies in the same individual on the same day or different days, sometimes being produced by irritation of the same regions, and at other times not by the methods first used, but by irritation of other areas or tissues. Irritation of one region of the body produces a reflex which gradually decreases in intensity. It is notable, however, that if the pulse is excited by irritating one region, although irritation of this region will soon lose its effect, irritation of another region will then cause a much more active reflex than if there had been no previous excitation of the pulse. Also, if irritation of the skin causes no reflex, percussion of the liver and subsequent irritation of the skin will frequently produce a reflex. The appearance of the reflex is sometimes very rapid and sometimes slow; it sometimes persists for a considerable period and sometimes rapidly vanishes. The reflex from irritation of the skin is much more marked than that from irritation of the muscles or from irritation of the bones. A change in the pulse after stroking a large area of the skin is not greater than that after stroking a small area; it is sometimes even less. [D. L. E.]

NEUROLOGISCHES CENTRALBLATT.

March 1st, [No. 5.]

No. 1. A Little-Known Tract of Fibres in the Periphery of the Anterolateral Portion of the Cervical Cord. By v. BECHTEREW.

No. 2. Intermittant Claudication. By GOLDFLAM.

No. 3. Amyotactic Dysphagia. By ROSSOLIMO.

No. 4. The Histology of the Changes Produced by the Compression of the Spinal Cord by Vertebral Tumors.—By BIELSCHOWSKI.

No. 1.—Von Bechterew refers to the band of fibres that he described in 1894 under the name of the "Olivary Tract." In regard to the direction in which these fibres pass, he believes that they invariably convey impulses downward, and of course, degenerate in the same direction, although Pick is of a contrary opinion. They probably have some relation to the lower olive, although there is not at present sufficient evidence to prove this point. It is not certain that they are similar to other tracts in this region. They have been described by various writers. J. S.

No. 2.—Goldflam has observed altogether the considerable number of 24 cases of intermittant claudication. The symptoms of this condition are the development of pain or paraesthesia in the legs after more or less prolonged effort at walking, which disappears after a brief period of rest, and reappears upon renewed exertion. During these attacks it has been observed that the pulse in the artery of the foot has disappeared, and the pathology therefore consists in more or less complete occlusion of the arteries of the lower extremity. The feet as a result are cold, cyanosed and slightly swollen and the muscles often slightly wasted. In the 24 cases observed by Goldflam pulsation in the dorsalis pedis artery was absent in 13 cases on both sides; in 10 cases on one side; and in 1 case it was very weak but palpable on both sides. The posterior tibial artery could not be felt on either side in 7 cases, and on only one side in 8 cases. In the remaining 9 cases the pulse was present. The symptoms of this disease may last for many years, but as the vascular condition is progressive they usually increase in severity, and from time to time there will be spontaneous attacks of pain. In addition there are often vasomotor disturbances that contribute to the symptoms. In some cases the paraesthesia exceeds the pains, as in the case of a man 30 years of age, exposed to severe weather in his occupation of forester. He suffered from a feeling of cold in the toes, particularly in the great toe, and the 4th toe. In this case pulsation was absent from the artery of the foot and there were evidences of

occlusion of the veins. He also reports the case of a man 40 years of age in whom the symptoms appeared on only one side, whilst on the other the artery pulsated freely and there were no pains. Another case in which the artery could not be felt in either foot, but the vasomotor symptoms were present in only one foot, and in that the pains occurred. The author also reports a case occurring in a man of 23, and involving only the left leg. In regard to the etiology of this condition it occurs naturally among older men. Twenty-one cases were over 30 years of age. In only one case was diabetes present, and in this the sugar appeared long after the claudication. Many of the patients were smokers, but some had never used tobacco, and the withdrawal of the weed had no beneficial effect. As 2 cases have occasionally been observed in the same family, it is possible that there is a family predisposition, and neuropathic disposition is also of influence. Syphilis and alcohol appear to be without any influence. Some of the cases closely resemble Raynaud's disease, as for example the following, occurring in a woman of 30 who had had a severe persistent pain in the ring finger of the right hand, that had failed to yield to any treatment, even operative interference. She also suffered from migraine, the attacks occurring from one to several times a month. Her parents were first cousins. Two sisters had distinct neurotic manifestations. The ring finger of the right hand was bluish at the extremity, and the whole hand was colder than the left. There were evidences of nephritis and weakness of the heart. The finger was finally amputated, but the patient died of heart disease a few months later. There was some thickening in the artery of the amputated finger. Goldflam believes that the purely functional Raynaud's disease may, in time, produce vascular changes in the peripheral arteries. In regard to the treatment of intermittant claudication, it should be directed partly to the prevention of the most serious complication, gangrene, and partly to the relief of the symptoms. The patient should be directed not to make any tours on foot. The feet should be kept warm, and should be protected against the wet. Alcohol and tobacco should be forbidden, and only milder forms of food consumed. No drugs are of value, not even the iodides, or nitrites. In a few cases a transient improvement may be obtained from electrical treatment. [J. S.]

No. 3.—Rossolimo reports 3 additional cases of difficulty in swallowing. The first, a woman of 38, with a bad hereditary history, who had suffered a great variety of forms of anxiety, developed fear of swallowing at the age of 36. This lasted about 3 months, and disappeared after the administration of sodium bromide and static electricity. The next patient, also a degenerate, a woman of 31, as a result of emotional disturbances had difficulty in swallowing, at first solids and later liquid foods. She was not improved by treatment. The third patient, a man of 26, without neuropathic heredity, had had a variety of infectious diseases. As a result of a severe cold he employed large quantities of snuff, causing dryness of the throat and difficulty in swallowing. This was relieved by local treatment. Renewed indulgence in snuff caused complete inability to swallow. These symptoms continued for 11 years. [J. S.]

No. 4.—Bielschowski reports the case of a woman who had had a tumor of the breast followed by metastasis to the spinal column, involving the bodies of the vertebrae from the 6th to the 8th dorsal, and causing pressure upon the spinal cord, without invasion of the membranes. Sections of the spinal cord from this region showed by Van Gieson's stain a peculiar sieve-like condition of the white substance, as a result of the degeneration of the nerve fibres. There were also numerous compound granular cells, some normal fibres, and various colloid bodies. The neuroglia was not markedly changed except in the posterior columns, where it was somewhat hyperplastic. The cells showed extreme degeneration, both by this and Nissl's method; the pia mater was normal. Microscopically a few black bodies were found, and a considerable number of fat granules in the small vessels. There was secondary degeneration in the pyramidal columns below the lesion and in the posterior column above the lesion. Schultze's comma degeneration was present in the posterior column below the lesion. Flechsig's oval area was not, however, involved. [J. S.]

ZEITSCHRIFT FUER ORTHOPAEDISCHE CHIRURGIE.

16. The Etiology of Deviations of the Trunk. P. LORZEN.
17. The Origin and Treatment of Club-Toes. C. HOFMAN.
18. Hysterical Scoliosis of the Wertheim-Salomonsen Type. J. SHOEMAKER.
19. Inexpensive Bandages. W. SENDER.
20. The Funnel Breast. CHLUMSKY.
21. The Orthopedic Work of the late Professor Albert. A. LORENZ.

16.—An uncomplicated lateral curvature of the spine is rare, as there is generally some asymmetry of the body. The physician must first decide whether a *true deformity* (scoliosis, kyphosis, etc.) is present, or whether there is merely an *anomaly of position*. From long study, Lorenz believes that every deviation in the shape of the trunk is the result of habitual position, assumed for rest or comfort. That this habit becomes a true deformity depends upon a diseased condition, either general, or localized to the vertebral column. Rarely a position which has been a habit for years may of itself become a deformity. Or an attitude, formerly assumed only on walking or standing, may, during illness, become permanent. This occurs more often among girls than boys. In early life, rachitis predisposes to deformity later. Deformity may occur from long standing, depressing disease or during convalescence from any illness. Chronic rheumatism may predispose to deformity, especially in those who habitually return to a position of rest. Pleurisy and sciatica act in the same way. The deformity following rheumatic myositis generally appears in the upper half of the trunk, with torticollis. Lumbago may cause a similar anomalous condition of the lumbar vertebrae. In such cases an infiltration appears in the affected muscle-fibres, which then remain distended, producing the deformity. In some of these cases, the spinal column is undoubtedly affected. In treating these cases, any existing local affection must first be cured. Apparatus will do harm in children in whom faulty position causes apparent deformity. Exercise is then needed. If true deformity exist, immobilization, with general and local treatment, is necessary. In all cases, the cause of the deformity must be sought, and removed. Finally, in cases which at first seem hopeless, bandages and systematic movements may be the means of discovering a local curable condition. [M. O.]

17.—Club-toes (hammer-toes) is the name given by Hofman to that deformity in which the toes are held in a position of plantar flexion and median adduction. With this exists some grade of flat-foot. Hofman describes two such feet, found accidentally in a cadaver. As in hallux valgus, there can be no suspicion of arthritic process. Hofman reports the case of a man who hurt his knee a year ago, since when he has voluntarily assumed the position in which the knee hurts least. This is the club-toe position, described above. The deformity is not fixed, and he can walk normally, but with pain in the knee. Hofmann concludes that club-toes, when not congenital, may exist whenever the toes assume an acquired position, due to some painful condition, and that this position may in time become a true deformity. Therefore the cause of the condition must be sought, and treated if possible. Tenotomy may be necessary, after immobilization. Finally resection of the first phalanx, or of the head of the metatarsal bone of the great toe may be performed. [M. O.]

18.—Shoemaker gives the details of two cases of hysterical scoliosis already reported by Wertheim-Salomonsen, and reports another case. All three were easily cured. The position assumed is the following: the patient stands on one leg, which is straight, extended, and somewhat adducted, the pelvis and shoulders are oblique, the pelvis higher and the shoulder lower upon that side on which the leg is extended, and there is a compensatory scoliosis. Shoemaker believes that the scoliosis is purely secondary, and that the condition should be termed the "hysterical hip position." The patients describe a feeling as if something had broken in the hip, upon flexing the extended leg. Salomonson believed this to be a physiological subluxation of the femur. But Shoemaker shows that anyone can produce it upon himself, and that it is due simply to the extended fascia lata slipping over the femur. The difference in the length of the legs is due to the different func-

tional activity of the two legs. Nothing abnormal can be found in either. Hysteria is undoubtedly the cause of this position. [M. O.]

19.—Sender describes Professor Turner's inexpensive substitute for plaster of Paris dressings, consisting of cellulose-wadding (lignin), ordinary glue, and gauze bandages. He describes its application. It is as good as Plaster of Paris, and much cheaper. When good glue is employed, the odor only remains a day. [M. O.]

20.—In 1860 an unknown Frenchman described that deformity of the anterior chest wall known as "funnel breast. The deepest point of the funnel lies in the sternum near the xyphoid process. The cartilages of the ribs rise convexly to either side of this median cavity. The depression is either oval or round; its depth varies, the deepest point lying below the intermammary line. The sternum shows backward kyphosis, either throughout its entire length, or at the lower end. The sternum may also show slight lateral curvature. The outward convexity of the ribs may be equal on both sides, or one side may project less than the other. Different grades of scoliosis or kyphosis are generally found with the deformity. It does not affect the rest of the thorax in any way. It is generally congenital, and may be hereditary. It is probably due to a defect of development, in individuals with a tainted family history. Rarely it is acquired, following rachitis, mediastinal tumors, etc. In its treatment, respiratory gymnastics should be used with trumpet blowing and local applications tending to decrease the atmospheric pressure, that the internal pressure may help to push out the deformity. Chlumsky reports in full five cases of funnel breast in children, with histories, and excellent photographs. [M. O.]

21.—Lorenz describes the varied and valuable work of the late Professor Edward Albert in the field of orthopedic surgery. The article is practically a review of the subjects and operations of interest to orthopedists during the past 50 years, with a detailed account of Professor Albert's opinions and operative procedures. [M. O.]

DEUTSCHE MED. WOCHENSCHRIFT.

March 21.

1. The Epidemic of Typhoid Fever in Goettingen in the Summer of 1900. P. FRAENCKEL.
2. The Surgical Treatment of Gastric Ulcer and Its Sequelae. W. KOERTE.
3. Experimental Investigations Concerning Compensation in Sensory Ataxia. A. BICKEL.
4. Indifferent Dyes as Stains for Fat. L. MICHAELIS.
5. Concerning the Reputed Immunity of the Hedge Hog to Cantharidin. L. LEWIN.
6. On Trigeminal Symptoms as Initial Signs of Tabes. V. FRAGSTEIN.

1.—Goettingen is usually completely or almost completely free from typhoid since the water supply has been a satisfactory one. Suddenly an epidemic, which altogether produced 51 cases, broke out during the early part of the summer of 1900. The cases were divided into three groups. Twenty-six were evidently from the same source; these occurred first. Seventeen others were from various parts of the city, and 8 cases were from the surrounding regions. All the first 26 cases occurred in persons who frequent one special inn; the source of the disease in this group of cases seemed to be definitely determined to be a well from which they had all frequently drunk, and which might readily have been contaminated with urine. The water of the well, however, apparently did not contain typhoid bacilli, and chemical analysis showed but slight increase of the organic matter. The second group of cases began to appear three or four weeks after the first group, and this second outbreak was probably started by the case of a servant who had washed for one of those first taken ill. The source of the third group could not be determined definitely. The cases occurred chiefly in young persons. The clinical picture was that of a severe infection, particularly in the first group. Seven of the 26 cases in this group resulted in death, while the general mortality in the Goettingen Clinic has for some years been about 8%. Of the remaining cases, those of the second and third group, but 2 were fatal. An interesting observation was the fact that bronchitis was unusually rare, only 11.5% of the cases showing it. The disease in the cases which were not fatal was usually prolonged, the average duration of treatment in the first series being 57 days, and there were 6 in this group who were treated for from 70 to

109 days. Six of the fatalities were due to severe general infection, 3 to complications. In 1 case there was a violent delirium shortly before death, the latter occurred from heart weakness. One case is noted in which there was an anomaly of some interest; the left coronary artery was absent. This anomaly has frequently been noticed, and is one which Fraenkel is inclined to believe is of some importance. The patient, a student, had shown no signs of heart weakness under ordinary circumstances of living, but there was a history that if he indulged in any very active exercise he had attacks of heart weakness. This Fraenkel believes was due to the fact that the single coronary artery was just about sufficient to maintain proper nutrition of the heart muscle under ordinary circumstances but did not suffice when special strain occurred. This patient showed marked degenerative changes in the heart, and Fraenkel believes that it is quite possible that the anomaly made the heart less resistant to the influence of the typhoid toxin. One case showed a wide-spread petechial eruption shortly before death, evidently a septic eruption. Bacteriological study of this case is not given. (To be concluded). [D. L. E.]

3.—Bickel discusses the source of the compensation which occurs in many cases of ataxia, particularly under treatment, and which may be observed in animals after cutting through the posterior nerve roots. He has made a series of investigations, in association with Jacob, and states that after compensation for the ataxia has been reached in animals, subsequent to cutting the posterior nerve roots, extirpation of the labyrinth causes a new onset of ataxic phenomena which are not followed by such marked compensation as was present previously. He also found that cutting off the sense-motor zones of the cerebral cortex in animals who had gained some compensation for ataxia, in the manner previously mentioned, would cause a new onset of marked atactic phenomena which were not compensated to nearly the same degree as had been the case after the preliminary lesion of the nerve roots. He also observed in one animal that division of the nerve roots was followed by the usual ataxia which was compensated largely. The subsequent removal of a small piece from each of the four cortical zones was followed by ataxia which again was largely compensated, but the removal of the remainder of the senso-motor zones was followed by a third onset of outspoken ataxia. Bickel decides that there is no doubt that the labyrinth has some relation to the production of compensation in ataxia. This is also certainly due in part to the motor-zones in the cortex, and probably other regions will be found to be important in this connection, particularly the optic thalamus, the corpora quadrigemina, and, in especial the cerebellum. [D. L. E.]

4.—Michaelis first gives a technical definition of indifferent stains. Acid stains are produced by the entrance into the molecule of an electro negative group, the basic stains by the entrance into the molecule of an electro positive group, while those which Michaelis terms indifferent stains are produced by the entrance into an azobenzol molecule of an indifferent group. He has found that these stains have a peculiar affinity for fats. A stain which is to be considered a stain for fats must have such affinity for fats as to diffuse spontaneously into fat from a 70% alcoholic solution of the stain. Michaelis particularly recommends scarlet R. He considers this even better than Sudan III. It does not stain cholesterin crystals, but it always stains fats of any kinds and stains nothing but fats. The staining is best carried out by using a saturated solution of the dye in 70% alcohol. [D. L. E.]

6.—While trigeminal symptoms are not uncommon in the later stages of tabes they are extremely rare as initial signs, and very few cases have been reported. In the case described, a man of 38, who had had syphilis 13 years previously, complained of a trigeminal neuralgia involving all the branches of the nerve, the pain being of a peculiarly sudden, lightning-like character which suggested a possible tabetic process. There was, however, an entire absence of other signs of tabes. Antisyphilitic treatment caused no improvement. A year and a half afterward the man was found to have a complete sensory paralysis of the trigeminal, with the exception of taste sense. He presented at that time very distinct signs of tabes. The seat of the lesion of the trigeminal must have been between the nucleus and the ascending root, or in both regions, because of the absence of disturbance of taste and of any trophic or vaso-motor symptoms. [D. L. E.]

MUENCHENER MEDICINISCHE WOCHENSCHRIFT.

March 12, 1901. (Jahrg. 48, No. 11.)

1. Subcutaneous Injections of Paraffine. By Meyer.
2. A Case of Cerebral Pressure Produced by a Rupture of the Sinus, Cured by Operation. By Bertelsmann.
3. Chronic Inflammation of the Spinal Cord with Ankylosis. By Bender.
4. A Case of Polyneuritis. By Zahn.
5. The Arsenic Question. By Stich.
6. A Case of Paralysis of the Point of Insertion of the Placenta. By Gerlach.
7. The Treatment of Panarthrititis. By Schulze.
9. Spring Mydriasis. By Gessner.

1.—Meyer, in view of Gersuny's suggestion that hypodermic injections of paraffin could be used with advantage for cosmetic or mechanical effects, because they remain indefinitely in the tissue without causing any reaction or being absorbed, has injected animals with various quantities of this substance, and has found that as a matter of fact, a considerable portion was gradually removed from the original mass and could be found in the lymph glands. Other animals had definite quantities injected into their bodies, and a very careful analysis was made to determine how much remained. It was found that one rabbit in 4 weeks lost 20% of the injected mass, and another in 8 weeks more than 50%. [T. S.]

2.—The patient, a woman of 40, had been violently thrown upon the pavement, and received a severe blow upon the back of the head. She immediately became unconscious, then partially regained consciousness for a short time, after which she had general convulsions, vomiting, and slight paralysis of the face. As the patient's condition grew worse, and she was apparently moribund, an operation was performed. At the seat of injury the brain showed all the symptoms of compression, and as the dura was lightly dissected away from the skull, a considerable quantity of dark blood gushed forth. There was also blood beneath the dura, and this was accordingly opened and pressure relieved. The bleeding apparently came from the torn sinuses at the torcula. It was arrested by tampons, and the patient subsequently had an uninterrupted but slow recovery. It is possible that in this case the injury had not completely torn the sinuses, but that the subsequent vomiting had so increased the cerebral pressure that it had ruptured. Subsequently further hemorrhage was caused by the convulsions. [J. S.]

3.—Bender reports the case of a girl 24 years of age who had been obliged to work 9 or 10 hours a day in one position for 9 years. Four years ago she began to have pain in the back, especially in the morning. This extended to the neck, and gradually she perceived stiffness of the spinal column. Her present condition is as follows: She has total ankylosis of the spinal column, with slight kyphosis of the cervical region, and extension of the thoracic region. Slight tenderness of the first dorsal and first lumbar vertebrae, fixation of the thorax, so that the respiration is purely abdominal; some atrophy of the muscles of the back and shoulders, but absolutely no involvement of any of the other joints. Otherwise the patient is apparently healthy. The case corresponds to the rhizomelic spondylosis of the type of Von Bechterew, with the exception that there is no hereditary factor. Bender believes that this case is best explained by assuming an ossification of the intervertebral disks. [J. S.]

4.—Zahn reports a case of polyneuritis occurring in a woman 32 years of age, who had had no infectious disease, who was not exposed to any intoxication, and had not received any injury. The first symptoms were rapid fatigue in the legs after walking, then difficulty in moving the arms, and finally severe pains in the limbs. There was marked impairment of memory. She became irritable and moody, and was brought to the hospital, where it was found that the symptoms of chronic multiple neuritis were present, with slight contracture of the left knee. The paralyzed muscles showed the reactions of degeneration.

The patient was treated with electricity, rest and massage, and rapidly improved. She died, however, of another disease. Microscopical examination of the crural nerve in the spinal cord was entirely negative. The interesting features of the case are the distribution of the lesions, that is to say, chiefly the extensors of the legs, and the absolute impossibility of discovering any cause. [J. S.]

5.—Stich reports some interesting cases; one in which arsenic was obtained from the stomach contents of a woman who had been poisoned by placing a large quantity of arsenic in the vagina. This was evidently a form of excretion with the gastric juice. In another case, a girl of 21 showed the presence of arsenic in the stomach contents and feces, and arsenic was also discovered in the organs of her 3 months' fetus. In a third case, a man who had taken enormous quantities of arsenic for the cure of a skin disease, showed the presence of a perceptible quantity in the urine. Snails were then poisoned with arsenic, and it was found that there was a general dilation of the lymph vessels, increase in the quantity of pigment, fatty degeneration of the protoplasm of the parenchymatous cells without any symptoms of inflammation. Plants were also poisoned, and it was found upon analysis that they absorbed very little of the poison. [J. S.]

6.—Gerlach reports a case of persistent hemorrhage resulting from paralysis at the insertion of the placenta. After all other methods of stanching had failed, he packed the uterus with gauze soaked in a solution of ferric chloride. The patient recovered. [J. S.]

7.—Schulze having had occasion to treat a case of pan-arthritis of the thumb in which operation was refused, observed that after the expulsion of the necrotic distal phalanx, the callus that had formed about it took its place and was capable of performing all its functions, the only defect being that it was slightly wider. He subsequently treated other cases expectantly with like results. [J. S.]

DEUTSCHE MEDICINISCHE WOCHENSCHRIFT. . .

March 14, 1901. (Vol. 27, No. 11.)

1. A Biological Proof that the Albumin in the Urine of Nephritis is Derived from the Blood. V. E. MERTENS.
2. Concerning the Question of the Destruction of Tubercle Bacilli in Fatty Foods. A. GOTTSTEIN and H. MICHAELS.
3. Concerning Lipochrome of the Ganglion Cells. M. ROTHMANN.
4. Erythema Exsudativum Multiforme Following Chemical Irritation of the Urethra. J. HELLER.

1.—Treated editorially.

2.—The authors have further investigated the question of the degree of heat to kill tubercle bacilli in fats, and the time of exposure needed for this purpose. They took a mixture of fats which became fluid between 40° and 50° C., and afterwards solidified at about 25° C. They then gradually brought the oily mass to a temperature of 87° C. and injected animals at once after it had reached this temperature, as well as after five, fifteen, thirty, forty-five and sixty minutes. The 13 animals which were injected with the mass after it reached 87° C. escaped tuberculosis without exception. They decide, therefore, that heating for five minutes or longer to a temperature of 87° C. is quite sufficient to sterilize oil infected with virulent tubercle bacilli. This is contrary to the statement of Rabinowitsch. [D. L. E.]

3.—Rothmann directs attention to the fact that the pigment found in the ganglion cells is of fatty nature. He then reports his results from the study of a number of animals which had advanced to what was for their species an old age. Horses over fifteen years of age contained large numbers of these granules in the ganglion cells, as did the cells of an old dog, and he decides that the presence of this pigment in the ganglion cells is proportionate to the age of the nervous organs examined, and he thinks that it may be possible by this means to tell fairly closely the age of the animal. [D. L. E.]

4.—The case reported was that of a man of 33 who had had chronic gonorrhea in '92, who had had an acute exacer-

bation in '93, and a similar occurrence in '97. He had married two years later and infected his wife, but under treatment seemed to become entirely well. In October, 1899, after bathing the penis in 20% creolin he had marked swelling of the organ, afterward followed by swelling of the right wrist and fingers and back of the hand, with a free secretion of sero-purulent fluid from the urethra, which contained no gonococci and very little diplococci, but a large number of other cocci, together with a number of pus cells. Soon after he had a general eruption of erythema multiforme which persisted for over a month with occasional exacerbations. Soon after this, however, he recovered entirely. This is said to be the first case in which chemical irritation of the urethra caused such an outbreak. The skin affection has been observed with gonorrhea or other inflammation of the urethra, but not as a result of the irritation may be considered an auto-intoxication, and in this case he thinks that it was an auto-intoxication from the serum secreted in the urethra and into the skin following the irritation of the creolin. [D. L. E.]

JOURNAL DES PRATICIENS.

March 23, 1901. (XVme. Annee, No. 12.)

1. Electrical Treatment in Spasmodic Stricture of the Esophagus. H. BORDIER.
2. Pyramidon. M. DEGUY.
3. Worms in Appendicitis. L. METCHNIKOFF.
4. Antidiphtheritic Serumtherapy at Present. H. GILLET.

1.—Spasmodic stricture of the esophagus is a neurosis which may be idiopathic, with emotion; symptomatic, with irritants, poisons, etc.; or sympathetic, with pregnancy. Its main symptom is dysphagia, either complete or incomplete. It may occur during a meal, in a healthy individual, with pain, some dyspnea, and anxiety. Its duration varies from a few moments to days, or even weeks. It is often intermittent, and then persists for years. The point of the stricture can be found by passing an esophageal bougie, which, when left in place, will often cause a gradual relaxation of the muscle-fibres in spasm. Many methods of dilation have also been tried. But electricity acts in a far superior manner. It may be applied directly or indirectly. In the indirect method, both sides of the neck are treated daily with galvanism, to affect the vagus and pneumogastric nerves. Directly, electricity is given in three ways. In all, an esophageal bougie with electrical attachment is introduced to the point of the stricture. Static electricity, the faradic, and the galvanic current are employed. Bordier advises the indirect method first. If this fail, faradization, and finally galvanization should be employed. [M. O.]

2.—After reviewing the literature of pyramidon, Deguy believes that it can be used in headaches, neuralgia, sciatica, and febrile tuberculosis; that it does not nauseate; and that it acts quicker, in smaller doses, than antipyrin. Its use is especially indicated in influenza, where it will reduce a rapid pulse, decrease a high temperature, and cause profuse sweating with the disappearance of all pain. In influenza one grain can be given every two hours; in migraine, etc., 5 to 7 grains should be given immediately. [M. O.]

3.—Four years ago, Metchnikoff, believing that intestinal worms could cause appendicitis, found ova of the ascaris lumbricoides and trichocephalus dispar in fecal matter from a young girl, aged 19, who had already had six attacks of appendicitis. Santonin was given, and repeated several times. She has been well since, over four years. Lemoine reported two similar cases, in a child of 12, and a man of 23. Both have been well ever since. He also quotes another case, a boy of 10, who recovered after passing two ascarides. It is impossible to state the exact condition of the appendix, as the four cases recovered without operation. But the clinical symptoms were typical of appendicitis. Other cases have been discovered in the literature, of worms found in the appendix, or in the peritoneal cavity after perforative appendicitis. The action of intestinal worms is both direct and indirect. The former is either mechanical or chemical, from their presence alone; the latter is the opening of a lesion which is an excellent field for the action of bacteria. After reporting some other cases, Metchnikoff concludes that in all cases of

appendicitis, the stools should be examined for worms or their ova; that when possible, santonin and thymol should be given, for the expulsion of the *ascaris lumbricoides* or the *trichocephalus dispar* respectively; that raw vegetables, such as salads, strawberries, etc., and unboiled or unfiltered water should be prohibited those with appendicitis, or subject to it; and that the stools of such people, especially of children, should be examined from time to time, or vermifuge given. [M. O.]

4.—Gillet advises small doses of diphtheria antitoxin for the initial injection. At 5 weeks he gives 5 c.c.; up to 2 years, 10 c.c.; after 2 years, 20 to 30 c.c., in simple cases. When more injections seem necessary, 10 c.c. are given. Only rarely does a child receive as much as 90 or 100 c.c. But when the attack is grave, 1500 to 2000 units may be given at once, repeated when necessary. Serum that has been heated to 58 degrees before being injected will be followed by fever eruptions, etc. In hospitals every suspected case should have an injection of 20 c.c. of serum at once, before the result of bacteriologic examination is known. In private practice, while not necessary, such an injection will always be safer. Should dyspnea be noted, the injection is needed. Should the bacteriologic examination be negative, yet the clinical signs typical, give the serum. For if the serum does no good, it at least does no harm. If the general condition remain low, if the membrane increase, or the temperature remain elevated, repeat the injection. Albuminuria is not a contraindication to the use of serum. Nor is the presence of other bacteria, associated with the diphtheria bacilli, a contraindication. The causes which prevent the success of the antidiphtheritic serum are the rapid toxicity of the bacilli, secondary infection, asphyxia from obstruction of the smaller bronchi, and failure of the organism to react. This lack of reaction decreases as the age advances. The serum should be used prophylactically whenever diphtheria bacilli are found in healthy throats, and when an epidemic exists. It seems impossible to obtain immunity to diphtheria. It recurs frequently. [M. O.]

ANNALES DE MEDICINE ET CHIRURGIE INFANTILES.

Februari 1st, 1901.

1. Instruction and Hygiene. E. PERIER.
2. Vegetative Rheumatic Endocarditis with Multiple Emboli; the Presence of a Bacillus analogous to the "Bacillus of Rheumatism," without Associated Microbic Infection. H. BARBIER and L. TOLLEMER.
3. Physical Education in Japan. M. YAMANE.

1.—E. Perier mentions the fact so often noted that school instruction for children is carried on quite regardless of the mental capacity of the growing child. In spite of the cry of alarm so often raised by medical men as to the dangers arising from faulty methods in the subsequent development of the child, those in authority have done nothing, in France, to make the school course more rational and the school hours less arduous. The course of study is quite out of all proportion to the ages of the pupils and the strain upon the nervous system of the children kept in enforced silence and in repressed nervous strain for long periods of time has been too little taken into account. The cry of reform should be heeded. [T. L. C.]

2.—Barbier and Tollemer discuss the gravity of the sequelae of acute vegetative endocarditis in childhood occurring at the mitral and aortic orifices, sometimes effecting the aorta itself and even the cardiac plexus. Very frequently pericarditis occurs with a formation of pericardial adhesions, and to this fact is due the greater part of the gravity of the pathological conditions which arise subsequent to the acute attack. One of the authors has previously published an account of the breaking up of vegetations from the mitral valve and the subsequent production of multiple emboli which seemed in particular to have obliterated almost totally the arteries of the left hemisphere. The history of the case is given. It began as a benign one. On the fourth day, however, without any apoplectic seizure, motor aphasia appeared suddenly, and later a progressive right hemiplegia, particularly affecting the face. Toward the end of the disease there were seen to develop the phenomena of meningo-encephalitis, and at the same time a bed-sore appeared over the right side of the sacrum and purpura developed. The authors call es-

pecial attention in this case to the number of emboli which penetrated the brain and produced areas of necrosis of varying intensity. The trunk of the sylvian artery was totally obliterated and the arteries of the internal striate and lenticule-optic bodies were also obliterated. The anterior cerebral arteries of the left side were not spared nor were certain arteries of the right hemisphere. These authors now present an interesting case of subacute articular rheumatism in a girl of eleven years, in which vegetative endocarditis occurred followed by multiple emboli, aphasia, extensive cerebral softening and death. Two thorough bacteriological examinations of the spinal fluid were made but were all negative save in one on milk in which evidently there had been accidental contamination. Careful notes of the autopsy are given, and thorough examinations were made of the vegetations on the mitral valve. A great number of bacilli were discovered which were extremely difficult to determine. They stained by Gram's method. The bacillus is slightly larger than the *b. typhosus* and a little longer. This bacillus was found only in the mitral vegetations, and they believe that it is identical with that described by Achalmé and Thierloir. [T. L. C.]

3.—Yamane of Tokio contributes a very interesting paper upon the wide-spread interest which has been aroused in physical culture throughout Japan. In all parts of the Empire large organizations with well equipped gymnasiums are flourishing and the course of instruction is fully systematized and carefully carried out. The writer believes that the health of both sexes will be greatly benefited under this system. Already a decided betterment of the moral tone has been observed.—[T. L. C.]

Irreducible Dislocations of the Shoulder.—Legueu, in *L'Independance Medicale* (April 10, 1901, No. 15), reports a case operated for old, irreducible luxation of the shoulder. In such cases two things must be considered, the lesions which prevent reduction, and the lesions which prevent reduction, and the lesions caused by the failure of reduction. The cause of the inability to reduce the dislocation may be a fragment of the tuberosity which has been broken off, with muscles attached; part of the joint capsule, or the tendon of the biceps, has interposed, or the head of the humerus is caught between muscles and tendons. None of these may be present, yet an unreduced or poorly reduced dislocation will become irreducible in time, generally after two months. Retraction of the fibrous tissue of the capsule occurs with sclerosis; bone will probably fill up the joint cavity; and the muscles near the point are altered. To overcome these three elements, three methods of treatment exist, gentle reduction, forcible reduction, and operation. The first are applied after an anesthetic, the former by Kocher's method, the latter with apparatus. Even when the dislocation is reduced by the gentle method, the joint cavity may be obliterated, and good functional use cannot result. The forcible method rarely achieves results. Operation then alone remains. Legueu prefers an antero-external incision, in the line of the deltoid fibers. This was done in the case reported, the head of the humerus being found under the coracoid process which it was necessary to cut. A partial fracture was found in the anatomic head, which had worked into the glenoid, and so prevented reduction. The glenoid cavity was deformed, the muscles and fibrous tissue altered. Resection was then performed at the level of the anatomic neck, the bone left being well rounded off to fit the glenoid cavity. With massage later, Legueu expects a good result. [M. O.]

Success Following Talma's Operation.—Scherwincky reported before the Moscow Therapeutic Society, *Meditsinskoje Obozrenie*, March, 1901) the further progress of his case of hepatic cirrhosis in which he performed Talma's operation about a year ago. The liver and spleen remained in the same condition; the circulation improved markedly; the collateral circulation was well established; digestion was also satisfactory, and the ascites did not recur. The patient, a woman, gained 14 pounds and became pregnant. [A. R.]

ARCHIVES DE MEDECINE DES ENFANTS.

March, 1901. (Volume 4, No. 3).

1. Congenital Cerebral Hemiplegia. WEILL and GALAVARDIN.
2. Diabetes Mellitus in an Infant Six Months Old. BAUMEL.
3. Subacute Diabetes at 22 Months. LE GENDRE.
4. Diabetes due to Hereditary Syphilis. LEMONNIER.

1.—The patient, a girl of 13, entered the hospital a month before death. Rightsided hemiplegia was first noted at the age of two months. She learned to walk later. Her right arm and leg are weaker than the left, and there is marked atrophy and shortening, with pes equinus. The heart is greatly hypertrophied, with a mitral systolic murmur. The liver is enlarged. Edema appeared, and rapidly increased. There was albumin in the urine, and the dyspnea became intense. A few rales were heard. She died suddenly. The autopsy showed a very large heart, with the mitral valve but little affected. Liver and kidney were congested and sclerotic. The left hemisphere, when the dura was removed, was but a cavity, filled with clear fluid. The upper anterior convolutions had disappeared, so that the left hemisphere weighed about half the right. The left crus, and the left side of the pons and medulla showed some atrophy. The walls of the cavity contained no nervous cells; the cord showed the left side smaller than the right; with marked neuroglial sclerosis, and a few motor cells, on the right side below the point of decussation. A diffuse interstitial myocarditis was found. There was no doubt that the hemiplegia was congenital. After a discussion upon the difference between true and false porencephalia, Weill and Galavardin conclude that this is a case of **pseudo-porencephalia**, because there was no idiocy, or other trouble of the intellect. Nor was there any cranial asymmetry [M. O.]

2.—Baumel, who believes that the pancreas is always the cause of glycosuria, reports a case of **diabetes mellitus in an infant of six months**. A general skin eruption appeared upon fourth day after birth. Two weeks before coming to the hospital, her lips, hands, and legs became swollen. She nursed constantly, and urinated frequently. The edema increased, there was meteorism, and the urine contained 1.5 grams of glucose to the liter. This gradually decreased, upon using calcium lactophosphate, and disappeared a month later. After a long discussion, Baumel concludes that the diabetes was caused by the nervous effect of teething upon the pancreas. Thus the calcium given, by helping the evolution of the teeth, cured the glycosuria. [M. O.]

3.—Le Gendre reports a case of **diabetes** occurring in a Jewish boy, aged 22 months, whose grandfather, who had diabetes, died of cirrhosis of the liver. Both his parents were extremely nervous before he was born. He was a precocious infant, ceasing to urinate in bed when 18 months old. He never had convulsions or night-terrors. It was first noted that he was growing thin about six weeks before his death. Next thirst was noticed. There were no signs of rachitis or tuberculosis. He urinated frequently, and again wet the bed. Sugar was found in urine in large quantity. Diet was instituted, and sodium arseniate and phosphate given. The liver was somewhat enlarged. The sugar in the urine increased in amount, and acetone was found. Extract of liver was given by rectal injection. Edema appeared, followed by coma and death. [M. O.]

4. A girl of seven and a half years had grown very thin during the past 3 months, drank 4 to 5 liters daily, and passed great quantities of urine. Lemonnier found her very thin, sallow in color, her skin dry. There was constipation with vomiting. The liver was enlarged, and sugar was found in the urine. Her father had acquired syphilis three years before marriage. This had never been treated. Her mother had had two miscarriages, with one premature still-born child. At birth the patient had coryza, a widespread papular eruption, and ulcers at the commissures of the lips. Mercurial inunctions were employed for a long time. A year later another syphilitic child was born. When Lemonnier had diagnosed diabetes, he ordered 25 grains of potassium iodide, and 30 grains of mercurial ointment daily. Two months later, the liver

had decreased in size, but the urine, though reduced to about half as much in amount, still contained sugar. The inunctions and iodide were given for three weeks at a time, alternately, over four months, after which polyuria and glucosuria had disappeared. Since that time she has had 20 inunctions every three months, and has not had a recurrence for over a year. She now eats everything. Lemonnier concludes that diabetes may be due to nervous lesions of the liver or pancreas, syphilitic in origin, cured by specific treatment; that diabetes may appear as a manifestation of syphilitic diathesis, without the occurrence of the above mentioned lesions; and that, finally, syphilis may create in children of syphilitics, a tendency to diabetes, in which specific treatment will do no good. [M. O.]

JOURNAL DE MEDECINE DE BORDEAUX.

March 24, 1901. (31me. Annee, No. 12.)

1. A Case of Cerebral Tumor Treated by Lumbar Puncture. ABADIE.
2. A Foreign Body in the Trachea. BRINDEL.
3. Influenza in a Child of Three Years and a Half. CORIVEAUD.

1.—Abadie reports a case shown by Professor Pitres, a woman of 42, who had constant violent headache. Since the age of 15, she always had severe headaches during menstruation. At 25, she had a slight sunstroke. The headaches then disappeared for a few years, but returned again. For the past few weeks they have been more violent, extended over the entire head, and continued night and day. The right eye seemed somewhat larger than the left, and the left pupil was dilated. Both pupils failed to react, and the visual field was retracted. **Diplopia** existed; also **left optic neuritis**. There was no vertigo or ataxia, and reflexes were normal. She vomited frequently and had no appetite. Mercurial treatment had no effect, nor had any other drug. Lumbar puncture was performed, 25 c.c. being withdrawn, followed by disappearance of the headache, with no recurrence since. Four days later she began to pick up, her eye-sight was again excellent, and she recovered. Yet she continued thin. The diagnosis of cerebral tumor seems certain. The headache and the optic neuritis were evidently due to increased intracranial pressure, after the removal of which, by lumbar puncture, they disappeared. [M. O.]

2.—Will be abstracted when completed.

3.—Coriveaud reports the case of a boy of three and a half years of age, who had just had whooping cough. He had been out of doors all day, though it was damp and cold, had no appetite, and had not slept well. Physical examination revealed nothing abnormal. The next day he coughed, complained of headache, and had a few moist rales in the bronchi. The cough becomes incessant, he vomited, and broncho-pneumonia developed. Counter-irritants were applied, and he was placed upon milk diet. The fever continued with changes in the resonance and rales. Baths were given to control the fever, which reached 106° F. Beside the baths, a little quinine was given. The cough resembled that of pertussis. He recovered quickly. Coriveaud believes that this was a case of influenza. [M. O.]

RUSSKI ARCHIV PATOLOGII, KLINITSCHESKOI MEDICINI I BAKTERIOLOGII.

January 31, 1901. (Vol. XI, No. 1.)

1. Absorption by the Blood of Minimum Quantities of Carbonic Oxide. S. I. KOSTIN.
2. Miliary Tuberculosis of the Mammary Gland. N. N. MICHAILOW.
3. On the Decomposition of Iodide of Potash in the Digestive Tract. A. STEPANOW.
4. Bacteriolysis of the Plague Bacillus. SH. MALIFITANO.
5. On the Study of Diffuse Congenital Hyperkeratosis. M. SNIESAREW.

1.—S. I. Kostin finds that the present methods of detecting small quantities of carbonic oxide in the air are either inaccurate or so complicated as to be inapplicable for ordinary sanitary analysis. By a series of elaborate experiments he found that blood serves as the best agent for absorbing small quantities of CO, providing the oxygen from the air is previously removed. He devised a simple and ingenious apparatus by which the air is first passed through a solution of cupric sulphate in ammonia which absorbs the oxygen. The blood saturated with the CO is then tested by Kunkel's tannin-test. The author believes with Kobert that small quantities of CO produced a slow form of poisoning which is responsible for many an obscure ailment. [A. R.]

2.—N. N. Michailow reports a very interesting case of primary tuberculosis of the breast. A woman, 33 years old, married and a mother of 4 children. During her last period of nursing the left breast became very painful, necessitating the removal of the child. On examination the right breast was found atrophied with practically no subcutaneous fat. On the skin a few small ulcers (tubercular) were scattered. The left breast was greatly enlarged, firm and heavy; the skin was edematous; the lymphatic glands along the lower border of the pectoralis major were considerably enlarged and some of them adherent to the skin and ulcerated. All the other organs were found normal, and the general condition good. For cosmetic reasons it was determined to remove only the mammary gland, leaving the skin intact. Under chloroform the gland as well as the lymphatics, including those of the axilla which were found diseased, were removed. On examination, both macro- and microscopical, the diseased tissue presented a characteristic picture of miliary tuberculosis. The author notes the strange fact that the affected glands showed coagulation necrosis but in none was cheesy degeneration found. The patient made an uneventful recovery. In connection with this case the author recalls another which came under his observation several years back. That was one of chronic mastitis developing in a woman of 30 at the end of lactation. The breast was enormously enlarged and infiltrated. During a seance of massage at one time there was a sudden discharge from the nipple of a large quantity of a gray fluid which resembled tubercular pus. Lack of experience at that time prevented a correct diagnosis, but now, recollecting the symptoms of the case, the author is positive that he had to deal with a primary tubercular abscess. [A. R.]

3.—A. Stepanow believes on the ground of his own observations as well as those of others that iodide of potash may become decomposed in the stomach under the influence of the acid contents of the latter and the nitrites of the saliva. This explains the gastric disturbances frequently observed after the administration of iodide of potash. This, however, is not constant. Usually decomposition takes place in the small intestine, the nitrites in this case being derived from the pancreas. [A. R.]

4.—Sh. Malfitano advances a number of arguments based on experiments which prove that bacteria possess proteolytic ferments which digest the bacteria,—a process of auto-digestion called by him "autobacteriolysis." These diastatic ferments are released from the bodies of the bacteria when the latter are placed in an environment unfavorable to their growth. Such an environment may be produced by adding various antiseptics, especially chloroform, xylol and thymol, to the culture-media, or by adding the diastatic ferments produced by other bacteria. The observations of Emmerich and Low would then be explained not by attributing specific bacteriolytic properties to the bacillus pyocyaneus, but the fact that the ferments of the latter, when added to a culture of the plague bacillus, act in the same manner as antiseptics do, namely, causing autobacteriolysis. [A. R.]

5.—M. Sniesarew describes a museum specimen of diffuse congenital hyperkeratosis in a fetus miscarried at the

seventh month. The pathological characteristics which distinguish it from Wassmuth's case are as follows: 1. The stratum corneum is greatly increased; 2. the stratum lucidum and stratum granulosum are still present; 3. the Malpighian layer is diminished; 4. the papillae are increased both in size and number; 5. the blood vessels are dilated; 6. the sweat glands are well developed; 7. hyaline degeneration of the connective tissue is present; 8. the reticular layer is diminished. [A. R.]

2. On the So-called Lipoma Arborescens. N. N. MICHAILOFF.
3. On Glycosolvol. S. W. LEVACHEFF.
4. A Method of Quantitative Determination of Urea in the Urine. A. P. BRAUNSTEIN.

1.—Considered editorially.

2.—Michailoff defines lipoma arborescens as a rare and extremely peculiar disease of the synovial membranes of the large joints and the sheaths of tendons characterized by the development on the surface of masses of newly-formed tissue. On account of the latter entering into the formation of these growths, the author does not agree with the nomenclature. He considers them as chronic inflammatory hyperplasia and believes that they are of tubercular origin, being produced by the toxins of the tubercle bacilli. He has seen several cases and describes one in which the growth appeared on the sheath of the extensor carpi radialis longior et brevior of the right hand. The tumor was removed and the patient recovered. [A. R.]

3.—Levacheff quotes the observation of Daehne, Martin Wiessenthal and Schedler on the remarkable curative effects of glycosolvol in diabetes mellitus. This substance was invented by a Dresden druggist Otto Lindner. It is made by the action of oxypropionic acid ($C^3H^5O^3$) on chemically pure pepsin and sodium theobrominate on trypsin. The product is claimed to possess the power of dissolving carbohydrates and is therefore indicated in diabetes. To facilitate the absorption of the drug the originator combines it either with powdered jambol seeds and aromatics or compound fluid extract of myrtle. The most extravagant claims made by Lindner incited the author to try his preparation in two typical cases of diabetes. The results obtained were greatly at variance with the statements of those who have used the drug before him. The liquid preparation exerted no beneficial effect whatever; the powder did reduce the amount of sugar in the urine but only when very large doses, far in excess of those recommended, were employed. The conclusion, therefore, is reached that the virtues of this preparation reside not in the glycosolvol but in the jambol which is a well known and apparently quite a potent remedy. [A. R.]

4.—Braunstein points out the inaccuracies in the various methods employed for quantitative determination of urea. For accurate work he suggests the following: 5 c. c. of urine are precipitated by 5 c. c. of a mixture of barium chloride and barium hydrate (250 grms. of barium chloride and 50 grms. of barium hydrate to the liter of water) and 100 c. c. of alcohol and ether (2:1) added. On the following day the mixture is filtered and the filter washed 6-7 times with ether and alcohol. The filtrate is evaporated at a temperature not higher than 55 C. until 10 c. c. remain. Just before this point is reached a little distilled water with a small amount of MgO is added. The 10 c. c. of the filtrate are then put into a small Erlenmeyer flask containing 10 grms. of crystalline phosphoric acid and 7 c. c. of liquid phosphoric acid. The whole is heated in an airbath at 140-145 C. for 4-12 hours. When cool, the nitrogen is determined by Kjeldahl's method. [A. R.]

The Philadelphia Medical Journal

A Weekly Journal Owned and Published by The Philadelphia Medical Publishing Company and Conducted Exclusively in the Interests of the Medical Profession

JAMES HENDRIE LLOYD, A.M., M.D., *Editor-in-Chief*
JULIUS L. SALINGER, M.D., *Associate Editor*
Assistant Editors

VOL. VII, No. 19

MAY 11, 1901

\$3.00 PER ANNUM

The Therapeutic Monthly.—The Philadelphia Medical Journal wishes to call the attention of its subscribers to the fact that each full paid subscription entitles its holder to a free copy of *The Therapeutic Monthly* until its expiration. It is only necessary for the subscriber to send a postal card to The Philadelphia Medical Journal, expressing his wish to receive the Monthly. We repeat this notice, which will not add one cent to the income, but, on the contrary, a considerable amount to the expense of this journal,—because we want all our subscribers who care for a first-class Therapeutic paper, to make the fullest use of their opportunities. The Philadelphia Medical Journal has secured a large number of copies of *The Therapeutic Monthly*, but a great many have been ordered already, and after the number secured has been exhausted, this offer will be withdrawn.

Dr. Gaylord's Paper on the Cause of Cancer.—In another column of the present issue we give a full abstract of the eagerly awaited article on the parasite of cancer, by Gaylord. The author's claim to have determined the true parasite of cancer rests apparently upon the following facts: First, the discovery of a peculiar organism in the peritoneal fluid of a patient suffering with adenocarcinoma of the peritoneal cavity. Second, the discovery of similar bodies in a large number of tumors (carcinomas and sarcomas and even syphilitic gummas) which he has examined. Third, the identification of these bodies with Plimmer's bodies, and the determination of their relationship to Russell's fuchsin bodies. Fourth, a certain peculiar series of changes that take place in the bodies when the fluid in which they are contained is kept in a thermostat. (These are analogous to sporulation.) Fifth, the production of small white nodules in the lungs of animals injected with this fluid, that resemble adenocarcinoma and originate in the columnar epithelium of the bronchi. Sixth, the discovery of the parasites in the epithelial cells of these growths.

We must confess that we feel greatly disappointed in this paper, and this is not altogether justified, because Dr. Gaylord does not publish it as a finished presentation of his views, but promises in the

near future a second article in which he expects to deal with the really serious part of the subject, the cultivation and inoculation of this organism. For the present he is content with a description of the various observations and experiments, the results of which we have given above. One of the most interesting features, and one that will require a very careful explanation, is the analogy of this organism to the vaccine bodies of Gorini and Funk, and the statement that they belong to the protozoa and not to the blastomycetes. Gaylord admits that the cultures made by Plimmer, which the latter regards as cultures of his own organism, are true blastomycetes, and the only inference that we can draw is that Plimmer has been guilty of gross inaccuracy in his work, and has mistaken a contamination for a growth of his bodies. It is interesting in this connection to recall the statement of Schaudinn, a zoologist, working especially with the protozoa, that the so-called cancer bodies—and he was familiar with preparations stained by Plimmer's method—have no resemblance whatever to the protozoa or coccidia. It is very curious also, that such a vast number of experiments (Fischel, Duplay and Cazin, Plimmer, Senn, etc.) made under conditions very similar to those of Gaylord—that is to say, intraperitoneally and intravenously—have been fruitless. It is unfortunate, perhaps, when we read of the forms of peritonitis produced by intraperitoneal injections, which are apparently inflammatory in nature, that we are irresistibly reminded of the work of Adamkiewicz, who obtained such remarkable results by the intra-cerebral implantation of fragments of carcinoma, results that could not be confirmed by other observers.

But when all is said and done, we must take personal prejudice into account. Gaylord admits that his feeling toward Sanfelice's results was somewhat modified by his acquaintance with that gentleman, and by the recognition of his honesty and earnestness; and our acquaintance with Dr. Gaylord has made exactly the same impression upon us. If his paper is at present incomplete and unsatisfactory, it is because his results, although clear enough to himself, are not capable of the accurate scientific

demonstration that is insisted upon before the scientific world is ready to accept them. How often has it occurred that important discoveries have been placed before the world in such form as to create considerable skepticism regarding their truth, and if Dr. Gaylord refuses to publish a series of experiments that have not yet been conducted to completion, he deserves rather to be congratulated than condemned, and we should endeavor to curb our natural impatience.

It is interesting in this connection to note that Musser and Sailer have recently reported a case of infectious pseudo-leukemia, in which they were able to produce tumors resembling lymphoma in the lung of a rabbit, into which they had injected intravenously some of the patient's blood. Although Lengemann has been unsuccessful with his experiments undertaken by this method, there is much reason to believe that by it the question of malignant tumors, and perhaps other diseases, is on the verge of solution. It would be curious, and yet perhaps not altogether to be regarded as a cause for surprise, if the suggestion of Smith and Washburn, that there are many forms of infectious granulomas hitherto not recognized as such, should turn out to be true, and if some of these forms proved to be the types of malignant tumor that can be conveyed to certain of the lower animals.

A Noteworthy Meeting.—It is seldom that a more important or more instructive meeting of a medical society is held than was that of the Association of American Physicians, at Washington last week, under the presidency of Professor Welch, a report of the proceedings of which is published in another part of the current issue of the *Philadelphia Medical Journal*. In addition to important clinical papers on the first day a very interesting and suggestive one was read by Dr. Herter, of New York City, on "The Acid Intoxication of Diabetes and its Relation to Prognosis," with valuable additions by Drs. Pfaff and Jocelyn, of Boston. The recent work of these men and others seems to indicate that the day is not distant when a new light is to be thrown on this obscure subject. In the evening most instructive micrographic demonstrations were given by Dr. Bond and Dr. Ernst, of bacteriological subjects, and by Dr. Councilman, of the lesions of interstitial nephritis in diphtheria. Rare morbid specimens were exhibited by Dr. Welch. On the second day two contributions of great importance were made, that by Drs. Flexner, Barker, and Novy, reporting their studies of the plague in San Francisco. It will be remembered these physicians constituted a commission appointed by the United States Government to investi-

gate the cases of plague in San Francisco. Even of greater importance to us in America was the report of Drs. Reed and Carroll, of the U. S. Army, of their researches, which have gone so far to prove the mosquito theory of the origin of yellow fever. An account of their work was reported at the Pan-American Congress at Havana in February, and has been made known to us through the columns of the *Journal of the American Medical Association*, and commented upon editorially in a previous number of *The Philadelphia Medical Journal*; but it was a great privilege to hear these facts presented so clearly and impressively by Dr. Reed. In the remainder of the day many valuable papers were read, notably one by Dr. Osler, on the Spinal Form of Arthritis Deformans, and another by Drs. John K. Mitchell, Flexner and Edsall, on the Chemical and Microscopical Results of the Examination of three cases of Family Periodic Paralysis. On both the first and third days other papers of clinical interest were presented, conspicuous among which was that of Dr. Thayer, on "The Presystolic Murmur," and that of Dr. Biggs, of New York, on "The Relative Prevalence of Bright's Disease in New York, London and Berlin."

Puerperal Septicemia Among Italians in This City.—We have seen certificates proving that four women have recently died of puerperal fever in the section of this city known as "Little Italy," and we are credibly informed by a reputable Italian physician that these four cases all occurred in the practice of one particular Italian midwife. This physician has taken pains to trace these cases, and also to make himself familiar with the methods of this woman. He informs us that her "practice" is careless and dirty to the last degree, and that these four cases are entirely due to her negligence. It can readily be imagined that the environment of her patients is not conducive to the most scrupulous asepsis, but it certainly does seem that there should be some way to stop the career of a slovenly midwife, who is thus strewing death in her path. It is not to the credit of any large American city at the present date that such a thing should be allowed to proceed without some official notice and some prompt corrective. In this period of preventive medicine and antiseptic midwifery, such a harvest of death in the practice of one midwife is scandalous. We imagine it would be within the province of the coroner to investigate this slaughter and bring the perpetrator to a speedy reckoning with the law. Any physician or midwife who has one case of puerperal fever faces a grave responsibility, but by the time he or she has four cases in rapid succession, that practitioner owes it to the public to purify and explain.

The Sesquicentennial of the Pennsylvania Hospital.—When in 1750 Dr. Thomas Bond (who seems to have been the real founder) solicited the aid of his friend, Benjamin Franklin, to further his scheme for founding a hospital in Philadelphia, he builded better than he probably knew or imagined. When the Provincial Assembly approved the act establishing the Pennsylvania Hospital (7th February, 1751), it met with some opposition from the country members, who said that the cost of medical attendance would alone be enough to consume all the money that could be raised—an objection which nowadays would not have much weight, and which at that time was met by Drs. Thomas and Phineas Bond and Dr. Lloyd Zachary, who offered to give gratuitous services for three years. This was probably the first occasion when the now familiar cry of "hospital abuse" was or could have been raised in Philadelphia. Dr. Zachary and the brothers Bond may possibly have had to face some such prejudice when they quieted the fears of the country members by promising that the Pennsylvania Hospital should be free. And free it has been, and widely benevolent, for one hundred and fifty years. It is a pioneer hospital, not only of a city and a province, but of a nation and a continent. The country members who demand, when they vote an appropriation, that the hospital which gets it shall be free (especially to the country members and their friends) are still with us, and we need not celebrate their sesquicentennial—but the old hospital with its traditions, its architecture, its noble record, is with us, too, and the opportunity is here for the celebration of its foundation in accord with its dignity and its usefulness. The managers have decided upon the 11th and 18th of this month as special fête days.

Electricity and Nerve Force.—The statement is not infrequently made that nerve force is identical with electricity, but there is little scientific ground for such a claim. The two forces are distinguished in a variety of ways. Thus, the speed at which they travel is very unequal; the nerve impulse travels at the rate of only about one hundred to one hundred and twenty feet per second, while the rate of electricity is vastly greater. But while the two forces are apparently not identical, it is true that the generation of nerve force seems to be accompanied by electrical phenomena. This may be merely in accord with the fact that all chemical changes are thus accompanied; as, for instance, the reactions between the elements in a Leclanché jar. Vito-chemical reactions in a neuron-body probably in the same way generate electrical force, but this is not necessarily the same thing as the nerve force itself. Another, and still more potent, argument is

based on the fact that nerve force is variously differentiated until in its psychic manifestations it reaches its highest display. This would be quite inconceivable of such a force as electricity, for certainly no one would say that thought and consciousness are merely electrical phenomena.

M. August Charpentiere has recently made observations which tend still further to prove that the two forces are distinct. He found that an electric stimulation of the nerve trunk causes a double transmission. (1) An almost instantaneous transmission just as in an ordinary conductor. This is evidently the electric current. (2) A current, also with electrical phenomena, transmitted at the very moderate speed of the nerve-impulse (65 to 100 feet). That this true nerve-impulse is accompanied, however, by electrical energy is proved by the fact that it can send a stimulus over a wire to a nerve in another animal and thus cause a response. But Charpentiere found that a second, third, and even fourth impulse or wave is carried over this wire, the inference being that the nerve-impulses are "oscillatory." This latter display is probably simply in accord with the idea of Schaefer and Horsley, that neurons have a rhythmical discharge. M. Charpentiere's observations are discussed in the *Revue Scientifique*.

The Death Rate from Influenza.—In the Monthly Bulletin of the Chicago Health Department for March, 1901, the leading article is devoted to the discussion of the effect of influenza upon the morbidity of the city. After calling attention to the rapid increase in the death rate from pneumonia, and to a less extent from other pulmonary conditions, they discuss the clinical manifestations of this disease, and the great importance of its recognition at the very incipency of the epidemic. This can only be accomplished by careful bacteriological examinations which the Chicago Board of Health is now prepared to undertake, systematically. With the "culture tube and microscope," they believe that the epidemic can be, to a certain extent, controlled. However, they admit that the disease spreads with extreme rapidity, and affects the clean (hygienically) as severely as the unclean.

The great difficulty in all these epidemic diseases is to educate the public. It is astonishing how hopelessly ignorant the medically uneducated are; how ready they are to grasp at cure-all straws; to believe blindly the alleged efficiency of drugs; to expect their physicians to keep them well, just as Torquata Tasso expected of his physician, without disturbing the reckless tenor of his life, or obliging him to do anything that was essentially disagreeable. Persons intelligent enough in their own line are often entirely unwilling to put themselves to

any serious inconvenience in order to prevent the ravages of an epidemic of which they are not as yet personally the victims. We have frequently been impressed by the curious indifference on the part of the people to these things. By this we do not mean that they foolishly expose themselves to the presence of patients suffering with well-known contagious disease; indeed, in some cases, such as leprosy, they are panic-stricken if a single case of this nature appears in the community; but we allude to their unwillingness to adopt even mild measures to prevent the spread of fatal epidemics.

Therefore, articles such as this of the Chicago Health Board, in which stress is laid upon the terrifying aspects of the disease, are to be strongly commended, for they should serve to some extent to arouse the public, not so much from its sense of false security, as from its indolence and indifference.

Hydrophobia.—Dr. D. E. Salmon, Chief of the Bureau of Animal Industry, Washington, D. C., has just issued in pamphlet form his study of rabies. Dr. Salmon relates the circumstances which led a few years ago to the discovery of the fact that hydrophobia was much more prevalent in the District of Columbia than any one had supposed. The disease, in fact, was not believed at the time to have occurred there with any frequency, but as a result of investigation quite a large number of cases were discovered in animals of various kinds. Thus in 1893 it was found that 11 dogs and 1 horse had the disease. In 1895, 4 dogs and 2 foxes; in 1896, 5 dogs; in 1897, 2 dogs, 1 cow; 1898, 7 dogs; 1899, 19 dogs, 1 cow and 1 cat, and in 1890, up to August, 32 dogs, 3 cows, 1 horse and 1 cat. Therefore, the total number of animals, nearly all of which were domestic animals, which had been found to be suffering from rabies, was 91. Twenty-eight persons were reported to have been bitten by these rabid animals. Dr. Salmon says that these developments were quite unexpected. It was not supposed at that time that rabies existed to this extent anywhere in the United States, and this discovery in the District of Columbia led to quite extensive inquiries as to the prevalence of the disease in the country at large. It was found that hydrophobia is more prevalent than is generally supposed, as the following figures for some of our larger cities clearly prove. In the decade from 1890 to 1899 there were 230 deaths from this disease in 73 cities. In Greater New York there were 27 deaths; in Chicago, 68; in Philadelphia only 8; but we desire to say here distinctly, with reference to these reports in Philadelphia, that we do not consider them reliable. It is a well-known fact in this city that the officials in the coroner's office have declared openly their unbelief in the existence of such a disease as hydrophobia.

and that they have deliberately returned such deaths, in which all the scientific evidence was clear, as due to other causes. One coroner of this town is even reported to have refused to accept certificates of death from hydrophobia, and required that certificates be made ascribing death to other diseases. This high-handed proceeding, both against the public weal and the teachings of science, goes far, perhaps, to justify the opinion, given by Judge Yerkes, of Bucks County, that the coroner's office should be abolished.

We have not space, of course, to review the whole of Dr. Salmon's interesting pamphlet. The author gives both historical and scientific data of great interest and value. The disease is probably of great antiquity, for Homer is supposed to have referred to it when he mentions Sirius, the dog-star, or Orion's dog, as exerting a malignant influence upon the health of mankind. One great value of such publications as this of Dr. Salmon's, especially when they issue under the auspices of the Government of the United States, is that they tend to enlighten public intelligence, for this is needed in two directions. First, to disabuse the minds of the public of the almost superstitious fear with which hydrophobia is regarded. While it is undoubtedly one of the most serious affections, it is well that people should know that it is amenable to both prophylactic and curative treatment. This is one of the triumphs of modern science, which should never be allowed to be forgotten. Secondly, such a publication is much needed to counteract the influence of a certain skepticism, now somewhat prevalent, to the effect that there is no such disease as hydrophobia. These two extreme views of the disease are erroneous and, therefore, mischievous, and the only safe course is the medium course, to regard the disease not only as a reality and at the same time a grave affection, but one fortunately which is now often cured.

The Physiology and Chemistry of the Internal Secretions.—With the revival of organo-therapy in medicine, this time upon a truly scientific basis, physiologists and chemists have given increased attention to the study of the ductless glands. The April number of *The Practitioner* is devoted to the subject of organo-therapy and contains, among others, an excellent article by Dr. John Rose Bradford upon the physiology of these glands. Their activity depends upon what Brown-Sequard has called their "internal secretions," the term, external excretion, being reserved for the products of the glandular activity which are subsequently carried to the surface by means of a duct. Glands besides secreting, may excrete, and the distinction between these two terms lies in the fact that the

products of secretion are not elaborated by the activity of the gland protoplasm, but are withdrawn by it from the circulating blood. Glands, besides possessing an internal and external secretion, may elaborate an excretion. Some glands are restricted in function to the production of an external secretion, as, for instance, the salivary glands. The thyroid and suprarenal glands probably produce only an internal secretion, as far as our knowledge goes at present. The pancreas and the liver have the double function, and in the kidney we have an example of a gland in which the excretory function is well developed, although it is by no means settled that the kidney does not possess also an internal secretion. It is interesting to observe the ability of interchange of these functions in certain glands. For instance, the salivary glands, normally secretory, will excrete iodide of potassium when this is present in the circulatory stream; and the liver will excrete a large number of toxic substances from the alimentary tract, and we must not lose sight of the fact that in uremia the stomach will excrete urea in appreciable amounts. It would seem that the internal secretions are elaborated in response to the physiological needs of certain tissues of the body. The thyroïdin of the thyroid gland may be necessary for the performance of the normal activities of the central nervous system, and the internal secretion of the suprarenals seems to have an important function in maintaining the activity of the muscular coats of the blood vessels. The essential nature of the external secretions is that of a ferment with exceptions, as, for instance, the secretion of bile salts by the liver. This material is used over and over again, being poured into the intestine, then reabsorbed and carried back to the liver. We are ignorant whether this is true in case of the internal secretions, but we know that they are used in the metabolism of the various tissues of the body, and in the case of the pancreas, there is evidence of the formation of a body allied to a ferment. This seems to be exceptional. A very great deal remains to be explained in this field, as, for instance, the fact that the removal of all parathyroid tissue, although its actual bulk is small, is followed by the same effects as is the complete removal of all thyroidal tissue. This is in spite of the fact that the parathyroidal tissue seems to contain no colloid material, which is the essential product of thyroid activity. In 1895 Baumann discovered the presence of iodine in the thyroid gland, and this served to arouse renewed interest in the study of its chemistry. The thyroid seems to possess a peculiar affinity for iodine, but it has been proven that iodine is not invariably present in the thyroids of young infants. It is generally accepted that iodothyryn is the only physiological active constituent

of the gland, but Robert Hutchison states that if the presence of iodine in iodothyryn is essential to the activity of this substance, it is not so in virtue of its being iodine, but owing to the form of organic combination in which it occurs. Gley has recently declared, as the result of his research work, that the normal thyroid gland contains approximately ten times as much iodine as the hypertrophied glands of patients suffering from exophthalmic goiter. Regarding the function of the parathyroids, it is probable that they are concerned in removing something from the blood rather than adding anything to it. We know that the administration of the gland by the mouth will not ameliorate the symptoms which result from their removal.

The Value of Adrenalin as an Antidote in Morphin and Opium Poisoning.—Dr. Edward T. Reichert, in an article in this journal in the issue of March 9th, showed that morphin administered in minute doses to dogs profoundly depressed general metabolism, and stated that this depression is so wide spread as to probably involve the processes which are concerned in internal secretion. As a consequence of this fact, the intensification of the toxic effects of the drug is in part explained. Reichert has experimented recently with adrenalin, the active principle of adrenal extract, for the purpose of observing its action upon the internal secretions both in healthy and morphinized dogs. Dr. Reichert has reported the results of his investigations in the April number of the *University of Pennsylvania Medical Bulletin*. When given by the stomach or administered in any form, adrenalin is a decided circulatory and respiratory stimulant, and increases metabolic activity. Possessing these properties, Reichert claims that it should be pre-eminently useful in antagonizing the lethal influences of opium and its derivatives. He has found that a dose of 0.00025 gram per kilo exerts no distinct influence in a normal dog, but in the morphinized dog it is sufficient to prevent the profound decrease of general metabolism, and the fall of temperature caused by the morphin. This fact indicates that in morphin poisoning there is an involvement of the processes concerned in internal secretion. The drug seems to act as a depressant to the secretory processes of the adrenal gland, thus depriving the vital centers of their secretions. In making these observations, Reichert mentions the fact that very small doses of adrenalin seem to exert no effect in the healthy animal, for the reason that the quantity introduced is minute, and the normal supply being sufficient, the excess is destroyed, or there is a temporary inhibition of the secretory processes of the glands, but in the morphinized animal it is probable that the blood

lacks this normal constituent, and that the adrenalin introduced is not destroyed until its function has been performed. This theory seems to be borne out experimentally, in that when larger doses are given to normal dogs, effects are noted comparable to those in morphinized animals after much smaller doses. Reichert explains this by stating that the quantity being in excess of what can be immediately destroyed, or compensated for, the effects are comparable to a hypernormal state of the activity of the adrenal glands. From his studies of the action of adrenalin upon the respiratory movements, the heart, arterial pressure, general metabolism and body temperature, Reichert believes that this drug will be found of great value in opium and morphin poisoning, in failure of the circulation, and in the prevention of collapse in anesthesia. Minkowsky, among others, has also recommended adrenalin in the latter condition. The careful work of Dr. Reichert in this field makes the preliminary report, and his conclusions of great interest. Very minute doses of the drug only are required. Thus it is stated that 1-200,000 of a gram injected intravenously produces distinctive effects in man. Reichert observes that owing to the powerful vasoconstrictor local action of adrenalin, abscesses will likely follow its subcutaneous injection, and he recommends that if given by the stomach, it should be administered with alcohol in some form so as to increase the rapidity of absorption.

Reviews.

Atlas and Epitome of Ophthalmoscopy and Ophthalmoscopic Diagnosis. By Prof. Dr. O. Haab, Director of the Eye Clinic in Zurich. *From the Third Revised and Enlarged German Edition.* Edited by Geo. E. De Schweinitz, Professor of Ophthalmology, Jefferson Medical College, Philadelphia; Consulting Ophthalmologist to the Philadelphia Polyclinic; Ophthalmic Surgeon to the Philadelphia Hospital and to the Orthopedic Hospital and Infirmary for Nervous Diseases. With 152 colored lithographic illustrations and 85 pages of text. Philadelphia and London: W. B. Saunders & Co., 1901. Price, \$3.00 net.

The names on the title page are sufficient guarantee for the excellence of this work. Closer examination, however, will at once reveal features which could only be brought to the perfection they possess by careful selections and extensive clinical material. The beautifully executed lithographic illustrations show some of the hidden changes of the eyeball that are unlocked by the ophthalmoscope. Of no little value to the student of ophthalmoscopy are the illustrations representing the non-pathological changes in the normal eye-ground which so often mislead and confuse him. The plates showing the microscopical changes are characterized tinctorially by wealth of color and correctness of demarcation. To those general practitioners who value ophthalmoscopy as a means of accessory diagnosis this book will be of material assistance. Even the specialist will find careful reproductions of such conditions as "Retinitis Circinata," "Glioma of the Retina" and microscopical sections of "Hyaline Bodies (Drusen) in the Vitreous Layer of the Choroid." The text is con-

cise, free from typographical errors and admirably translated. Especially free is it from the "Germanicisms" so frequently observed in English translations, and so difficult to overcome. The publishers have placed the book on the market in such a manner, that it forms a valuable adjunct to the other atlases. [M. R. D.]

The Technique of Surgical Gynecology.—By Augustin H. Goelet, M. D., Professor of Gynecology in the New York School of Clinical Medicine; Consulting Professor of Gynecological Electro-Therapeutics, International Correspondence Schools, Scranton, Pa.; Fellow of the New York Academy of Medicine, and of the New York Obstetrical Society; Member of the American Medical Association; New York County Medical Association; Fellow of the Societe Francais d'Electrotherapie, etc. International Journal of Surgery Co. New York, 1900. Pp. 331.

This work is devoted entirely to operative technique, as its title implies, and no space is given to diagnosis, pathology or forms of treatment other than operative. In this respect it supplements many works on gynecology, which give only general directions. There is no hesitation, therefore, in devoting abundant attention to minor points which are of great importance to those unfamiliar with a given operation. The writer has the power, not possessed by all, of making clear that which he is trying to describe. In general he gives but one method of operating, the one which he considers best. This detracts somewhat from the value of the work, as the reader might care less to know what method was used by this author, than to find in a work on technique clear descriptions of those methods which have wide acceptance among the best operators. For example, the only method of shortening the round ligaments given is that of cutting down on the ligament within the inguinal canal, as practiced by Dr. Kellogg. The method is a good one, but many operators of very large experience prefer to reach the ligaments at the external ring, or to lay open the canal, and these methods merit description in a work on technique. So with lacerations of the perineum. To be sure, it might be said that the operations are too numerous to describe; but to confine the description to a simple triangular method with the apex in the centre above, layer sutures of catgut, or two purse string silver sutures for hurried work, is not doing justice to the subject. One might infer that the writer seldom does combined plastic operations at a single sitting, for if the peritoneum and anterior vaginal wall be properly sutured, the removal of silver sutures from the cervix is difficult, and such treatment of the canal as daily subsequent packing with iodoform gauze is out of the question. Seldom indeed will the operation of cervical repair be the only one done at a sitting in most hands. He uses stick sponges rather than continuous irrigation. He does not advocate the self-retaining vaginal speculum. He would carry conservatism in tubal surgery so far as in some cases to wash out and leave a tube in which ectopic pregnancy had occurred. How this can be reconciled with the very common history of repeated hemorrhage attacks after rupture, is not stated. He advocates the mass ligature only for tumor pedicles, and in vaginal ovariectomy sews in the ligature to prevent slipping. He believes that the ligation per vaginam of uterine arteries has a field in the case of tumors low down, but advises cutting the artery. The chapter on curettage and after-treatment as modified by conditions is very good. Many practical and suggestive points are to be found in the work, which will find appreciative readers. [G. E. S.]

A Case of a 7 months Extrauterine Pregnancy Operated on through the Vagina. A. Ph. Kablukoff (*Medicinskoje Obozrenie*, February, 1901,) reports a case of extrauterine pregnancy in a nullipara 30 years old. A well formed dead fetus of 7 months was removed through the posterior vaginal wall. Owing to adhesion, the placenta was left in situ. The post-operative period progressed without any complications, except for an elevation of temperature accompanying the gradual discharge of the placental tissue. [A. R.]

American News and Notes.

PHILADELPHIA NEWS.

Jefferson Medical College.—The annual commencement exercises of the Jefferson Medical College will be held at the Academy of Music on May 15th at noon. 142 graduates will receive their diplomas. Professor W. W. Keen will hold the commencement address. The alumni meeting will be held on May 14th, 7 P. M., at the Stratford Hotel, and the alumni dinner at 8 P. M. of the same evening.

Philadelphia School for Backward Children.—The Philadelphia School for Backward Children is asking the Board of Education to undertake the supervision of the school and to locate it in the Hollingsworth public school building, Locust above Fifteenth street. Medical School Inspectors and Hospital Physicians would do well to refer to this School all such children coming to their notice that are in need of individual instruction. The Board of Education and Councils no doubt will readily see the efficacy of this movement and they cannot give too much support to it.

For an Obstetrical Amphitheatre.—The University of Pennsylvania has received a gift of \$25,000 from Mrs. C. B. Newbold, of Philadelphia, for the erection of an obstetrical amphitheatre as an addition to the maternity department of the university hospital. The gift was made in honor of her mother, Mrs. Thomas A. Scott.

Whooping Cough Among Contagious Diseases.—The Hygienic Committee of the Board of Education decided to add whooping cough to the list of contagious, and considers it a cause for exclusion from the public schools.

Removal of Alms House and Insane Hospital.—Efforts are being made for urging the speedy removal of the Alms-house and Insane Department of the Philadelphia Hospital, (Blockley), to a more suitable location. The sum of \$200,000 has been made available for the erection of new buildings, through the action of Congress. ad Continental Europe—

Obituary.—Dr. Samuel Kuypers Lyon, at New York, on May 4, aged 60 years.—Dr. Harold Snowden, at Alexandria, Va., on May 5, aged 65 years.—Dr. Abraham Deyo, at Gardiner, N. Y., on May 5, aged 71 years.

Obituary.—Dr. Roy Ingliss, at Denver, Col., on April 23.—Dr. Henry Byron McKellops, at St. Louis, Mo., on April 24, aged 78 years.—Dr. Charles A. Eisenhart, at York, Pa., on April 23, aged 56 years.—Dr. George Dale, at Chicago, Ill., on April 25.—Dr. William H. Draper, at New York City, on April 26, aged 71 years.—Dr. J. A. Someville, at Marinette, Wis., on April 27, aged 59 years.—Dr. Joseph W. Benton, at Indianapolis, Ind., on April 28, aged 77 years.—Dr. James H. Woodburn, at Indianapolis, Ind., on April 28.—Dr. Jacob A. Sherman, at Plainfield, N. J., on April 29, aged 81 years.—Dr. M. B. Baldwin, at Wardencliffe, Mass., on April 30.—Dr. F. G. Brown, at Hutchinson, Kan., on April 29, aged 57 years.—Dr. Richard C. Baker, at Otego, N. Y., on April 24, aged 47 years.—Dr. William F. Creighton, at Alexandria, Va., on May 2.—Dr. Irving C. Rosse, at Washington, D. C., on May 3, aged 54 years.—Dr. David H. Bartine, at Merchantville, N. J., on May 3, aged 60 years.—Dr. M. Albert Rhoads, at Reading, Pa., on May 4, aged 53 years.—Dr. Orlando Mitchell, at Marshall, Mo., on May 3.

Vital Statistics of Philadelphia for the week ending May 4, 1901:

Total mortality	494	Cases	Deaths
Inflammation of the appendix 1, bladder 1, brain 21, bronchi 8, heart 1, kidneys 28, larynx 1, liver 5, lungs 55, pericardium 3, peritoneum 4, pleura 3, stomach and bowels 19, spine 3 ..	153

NEW JERSEY.

The Salem County Medical Society has elected officers for the year, as follows: President, Dr. E. E. De Groft; Vice-President, Dr. B. A. Waddington; Secretary and Treasurer, Dr. H. Chavanne; Reporter, Dr. W. H. Carpenter; Censor, Dr. N. S. Hires.

Cape May County Medical Society.—The annual meeting of the Cape May County Medical Society was held May 7. Several interesting papers were read, and at the close of the business session a banquet was served. The following officers were elected: President, John S. Douglass, of Tuckahoe; Vice President, Joseph Marshall, of Tuckahoe; Secretary, Nathan Cohen, of Wildwood; Treasurer, Randolph Marshall, of Tuckahoe.

NEW YORK.

New York State Hospital for the care of Crippled and Deformed Children. The opening of the Hospital will take place on Friday, May 17th, 1901 from 3-5. The Right Reverend Henry C. Potter, D. D., President of the Hospital, will preside. Short addresses will be made by Professor Robert F. Weir, M. D., of Columbia University; Professor A. Alexander Smith, M. D., of the University of the City of New York, and Professor William Polk, M. D., of Cornell University. A special train will leave the Grand Central Station at 2.06 P. M. returning will leave Tarrytown at 5.55 P. M. reaching New York at 6.35 P. M. Anyone interested may obtain tickets for the special train upon application to Dr. Newton M. Shaffer, 28 E. 38th street, New York City.

The American Congress of Tuberculosis will be held at the Grand Central Palace, in the City of New York, May 15th and 16th, and perhaps May 17th, 1901, in joint session with the Medico-Legal Society of New York. The medical profession of all countries have been invited to contribute papers to be read before this congress, in their behalf, by a committee selected for that purpose, in case of the inability of the author to attend, and to enable those who could not hope or expect to be present to participate in the

work and usefulness of the body. As the questions to be discussed involve medical legislation, legislators, lawyers, judges and all publicists who take an interest in the subject are also invited, both to enroll and contribute papers.

The governors of the American states and territories and of the Provinces of the Dominion of Canada have been invited to send at least three or more delegates.

The governor of Colorado has appointed the following delegates to represent the state of Colorado at the American Congress of Tuberculosis, to be held at the Grand Central Palace, in the City of New York, May 15-17, 1901: Dr. J. N. Hall, of Denver; Dr. Will B. Davis, of Pueblo; Dr. B. P. Anderson, of Colorado Springs; Dr. J. Tracey Melvin, of Sagauche; Dr. R. F. Graham, of Greeley, and Mrs. W. S. Decker, of Denver.

The governor of Kentucky has appointed the following delegates to the same Congress: Dr. J. N. McCormick, of Bowling Green; Dr. M. K. Allen, of Louisville, and Dr. Chester Mayer, of Louisville.

The governor of Vermont has appointed the following delegates to that Congress: Dr. Charles S. Caverly, of Rutland; Dr. Henry D. Holton, of Battleboro, and Dr. Truman, R. Stiles, of St. Johnsbury.

The governor of Washington has appointed the following delegates to this Congress: Hon. Watson C. Squire, ex-U. S. Senator from Washington, D. C.; Edward H. Thomas, Esq., of Whatcome, Washington, and Ralcy Husted Bell, M. D.

The Nicaraguan Minister has appointed the following physicians to represent Nicaragua at the Congress: Dr. Louis H. Debayle, 21 Irving Place, New York City, and Dr. Juan B. Sacasa, Columbus Hospital, New York City.

The governor of Alabama has appointed the following delegates from that state: Dr. W. H. Blake of Wetumpka; Dr. C. H. Jeringan, of Birmingham, and Dr. W. J. Kernahan, of Florence.

The governor of Missouri has appointed twenty-five delegates; the governor of Georgia has named twelve delegates, Iowa eight, Virginia three, and nearly every state and territory will be represented.

Similar invitations have been sent to the presidents of the Central and South American countries. Arrangements have been concluded for reduced railway rates throughout the United States and Canada. A letter has been sent to the delegates and officials by the President of the Medico-Legal Society embracing the following questions:

1st—What importance do you attach to preventive legislation as a factor in diminishing the spread of Tuberculosis?

2nd—Assuming the importance, necessity and utility of preventive legislation, how can the public be best educated and its sentiment aroused sufficiently, to secure the passage of preventive laws, and their enforcement after they are passed?

3rd—Which would you regard as for the best interest of the people?

(1) Legislation authorizing the employment of drastic measures for the enforcement of the necessary regulations, or,

(2) A broad policy of education of the masses, as to the cause, the danger and the remedy for a factor in diminishing the spread of Tuberculosis?

Kindly reply to this letter at once, because the time is so short; and if you will contribute a paper and enroll in the congress, do so.

Please send your reply to the questions as early as possible, so that I can publish your answer as a part of my contribution to the Congress, to be sent at least a month before its session to delegates, and in time, to awaken interest, and arouse discussion upon the subject at the Congress itself.

NEW ENGLAND.

Sterilizing Money.—Scarlet fever, which is epidemic in Keene, N. H., has caused the Cheshire National Bank of that town to sterilize all the money which passes through

the bank by means of a sterilizing oven which they have put there for that purpose.

Hartford County Medical Society.—The annual meeting of the Hartford County Medical Society was held April 17. Papers read were: "Etiology and Treatment of Sub-Acute Rheumatism," by Dr. Thomas S. O'Connell; "The Surgical Treatment of the Peritoneum," by Dr. Arthur J. Wolff; obituaries, Dr. Abner S. Warner, by Dr. Gordon W. Russell, Dr. Julian N. Parker, by Dr. William R. Tinker; "Gun-shot Wounds of the Brain," by Dr. Harmon G. Howe; "Typho-Malarial Fever," by Dr. Edward K. Root; "Ectopic Gestation," by Dr. Phineas H. Ingalls.

American Laryngological Association. The programme of the 23rd annual congress of the American Laryngological Association to be held at Yale University, New Haven, Conn. on May 27-28-29, is as follows: Monday, May 27th, morning session at 10.15 a. m. Roll call. Reception of Guests. Address of Welcome, by the President of Yale University. President's address, by Henry L. Swain, M. D., New Haven, Conn. Papers. 1 A leaf from the ancient history of the anatomy of nasal catarrh, Jonathan Wright, M. D. 2. Asymmetry of the nasal cavities, A. Coolidge, Jr., M. D. 3. Reflex epilepsy from nasal disease successfully treated by the removal of the intra-nasal cause, John O. Roe, M. D. 4. The supra-labial operation (Dr. Harrison Allen's) for deflection of the nasal septum, Arthur Ames Bliss, M. D. 5. Edema of the pharynx, palate and uvula following application of supra-renal extract, S. Solis-Cohen, M. D. 6. (a) Can we prevent secondary hemorrhages following nasal operations? (b) Epipharyngeal sarcoma in a boy (with radiographic study), Henry L. Wagner, M. D. 7. Chancre of the tonsils, J. Edwin Rhodes, M. D.

Afternoon session at 3 p. m. Papers: 8. Mouth breathing and its relation to disease of the nose, throat, ears and accessory cavities, Mayo Collier, M. D. 9. Diagnosis of adenoids in infancy, W. F. Chappell, M. D. 10. Serous disease of the maxillary antrum with a report of two cases, W. E. Casselberry, M. D. 11. Empyema of the antrum of Highmore in infants, Emil Mayer, M. D. 12. Abscess of the frontal, ethmoidal and sphenoidal sinuses complicated by adenoma of the posterior ethmoidal and sphenoidal regions, J. H. Bryan, M. D. At 4.15 adjournment to the Psychological Laboratory. Evening. Reception in Alumni Hall by the President of Yale University and the President of the Association. Tuesday, May 28th. Session at 10 a. m. Business meeting. Open only to fellows of the Association. Papers. 1. Discussion on general anesthesia in operations upon the nose and throat: (a) On the use of the A. C. E. mixture and ethyl bromide for adenoid operations, J. W. Gleitmann, M. D. (b) Nitrous oxide, chloroform and ether, T. R. French, M. D. 2. The tonsils from a purely clinical point of view, F. H. Bosworth, M. D. 3. The histology of the retrograde changes in the faucial tonsils of the adult, J. H. Goodale, M. D. 4. Vocal nodules, C. H. Knight, M. D. 5. The effects of cinchonism upon vocalization and articulation, Carl Seiler, M. D. 6. A study of the proper application of intubation in chronic stenosis of the larynx, W. K. Simpson, M. D. 7. A case of stenosis of the larynx following fracture; operation; recovery, A. W. Watson, M. D. 8. Some cases of paralysis of the right vocal chord, J. W. Farlow, M. D. 9. A note on tonsillotomy rash, Wyatt Wingrave, M. D. Evening. Annual dinner of the Association at the New Haven Lawn Club. Wednesday, May 29th. Closing Session at 10 a. m. Papers. 1. A report of a method of local treatment employed to eradicate the susceptibility of the nasal mucous membrane to hay fever, C. D. Rice, M. D. 2. The surgery of naso-pharyngeal tumors, D. Bryson Delevan, M. D. 3. Lymphadenocarcinoma of the nose (illustrated), M. Braden Kyle, M. D. 4. Note on the use of the electro-magnet for the extraction of foreign bodies from the air-passages, A. W. de Roaldes, M. D. 5. The cleft palate and its relation to speech, G. Hudson Makuen, M. D. 6. The laryngeal syringe in the treatment of laryngitis and bronchitis, Thomas Hubbard, M. D. 7. Aqueous sprays in diseases of the upper air-passages, G. V. Wollen, M. D. 8. (a) A case of sarcoma of the nose and naso-pharynx. (b) A case of thyrotomy for papil-

loma; a supplementary report. T. Melville Hardie, M. D. 9. Osteophytes of the nasal chambers, A. W. MacCoy, M. D. 10. Pedunculated fibroma of the esophagus obstructing the larynx, F. C. Cobb, M. D. 11. Report on three cases of tumors. (a) Osteo-sarcoma of inferior turbinate. (b) True papilloma of the nasal septum. (c) Sarcoma of branchial cleft, J. E. Newcomb, M. D.

WESTERN STATES.

Central Illinois Medical Association.—The twenty-seventh annual meeting of the Central Illinois Medical Association convened in Pana, Ill., April 30, for a two days' session. The attendance was the largest in the history of the association. The following program was rendered: "Puerperal Fever," W. K. Wright, M. D., Taylorville; "Diagnosis of Pericarditis with Effusion," S. E. Munson, M. D., Springfield; "Pulmonary Tuberculosis," Amos Sawyer, M. D., Hillsboro; "Suggestion as an Element in Treatment," W. T. Moffett, M. D., Blue Mound; "The Practical Value of the Cystoscope in Diagnosis," Joseph Milligan, M. D., Jacksonville; "Gastric and Duodenal Ulcers," with report of cases, Everett J. Brown, M. D., Decatur; "Report of a Case," Pierce Collins, M. D., Decatur; "Rheumatoid Arthritis," Frank P. Norbury, M. D., Jacksonville; "Some Notes on Course and Treatment of Pneumonia," W. A. Melton, Jr., M. D., Warrensburg.

The Oklahoma anti-cigarette law which takes May 1, 1901 is as follows: Section 1. That it shall be a misdemeanor for any person, firm or corporation to sell, offer to sell, or to bring into the territory for the purpose of selling, giving away or otherwise disposing of, any cigarettes, cigarette paper or any substitute for the same. Section 2. Be it further enacted that it shall be a misdemeanor for any person, except parents or guardians, either for himself or another, to give away cigars, chewing tobacco, or tobacco in any form, to a minor under the age of 15 years. Section 3. Any person convicted of the above misdemeanor, or for selling or giving away cigarettes or tobacco, or paper for the purpose of making such cigarettes, shall be fined for each offense in any sum not less than (\$50) nor more than two hundred (\$200), and any person, except parents or guardians, convicted of selling or giving away cigars, chewing tobacco, or tobacco in any form, to any minor under the age of fifteen years, shall be fined in any sum not less than ten dollars (\$10), nor more than fifty dollars (\$50) for each offense. Section 4. Be it further enacted that the grand juries shall have power to inquire into the alleged offenses committed under this act. Section 5. Be it further enacted that this act shall take effect from and after the 1st day of May, 1901, the public welfare requiring it.

The Detroit Medical Journal.—The initial edition of the *New Detroit Medical Journal*, under the editorial management of Dr. G. H. Stockwell, will be issued about April 15. It is announced that this publication will be devoted solely to the interests of the medical profession.

American Proctological Society.—The third annual meeting will be held at Hotel Aberdeen, St. Paul, Minn., June 4 and 5, 1901. The programme is as follows: First Day—Meeting of the Council, 1.30 P. M.; Executive meeting: President's Address, Dr. James P. Tuttle, M. D., New York; Primary Tuberculosis of the Rectum and Anus, with Report of Cases, Dr. Leon Strauss, St. Louis; Disease of the Sigmoid, Dr. George B. Evans, of Dayton, O.; Report of two Cases of Valvotomy, Dr. Samuel T. Earle, Baltimore; Treatment of Prolapse of the Rectum, Dr. J. Rawson Pennington, Chicago; Foreign Bodies in the Rectum, with Report of a Case, Dr. Lewis H. Adler, Jr., of Philadelphia; A Study of Simple Ulceration of the Rectum from a Clinical Standpoint, Dr. A. Bennett Cooke, Nashville; A New Method for the Painless Removal of Hemorrhoids, Dr. Thomas Charles Martin, Cleveland; Anal Pockets, Dr. Louis J. Krouse, Cincinnati; The Treatment of Recto-Colitis, Dr. William M. Beach, Pittsburg; Paper, Dr. George J. Cook, Indianapolis.

SOUTHERN STATES.

Richmond, Va.—The annual final exercises of the University College of Medicine, Richmond, Va., were held

May 2d. The graduates and the public were addressed by Dr. Charles D. McIver, of Greensboro, N. C. In the Medical Department there were 72 graduates; in the dental, 4, and in the pharmaceutical 6.

The Hunter McGuire Memorial Annex to the Virginia Hospital, erected at a cost of \$15,000 was dedicated with appropriate exercises on May 1st.

Dr. S. V. Sherrill who was recently relieved from duty as first assistant physician of the Southwestern State Hospital for the Insane at Marion, Va., has preferred charges against Dr. R. J. Preston, Superintendent of the same institution, on the grounds of "mismanagement, neglect and incompetency."

A New Medical Society, known as the Church Hill Medical Society has been organized in the eastern part of Richmond, Va., with 20 members. Dr. R. D. Garcin is president and Dr. B. A. Hord, secretary.

Association of American Physicians.—At the closing session of the sixteenth annual meeting of the Association of American Physicians, held May 2, the following officers were elected: President, Dr. James C. Wilson, Philadelphia; vice-president, Dr. James Stewart, Montreal; recorder, Dr. S. Solis Cohen, Philadelphia; secretary, Dr. Henry Hun, Albany, N. Y.; treasurer, Dr. J. Crozier Griffiths, Philadelphia; councilors, Drs. Frank Billings, Chicago, and Francis P. Kinnicutt, New York; representative on executive committee of congress, Dr. William Osler, Baltimore; alternative representative, Dr. Francis H. Williams, Boston.

The Louisiana State Board of Health has appointed the following resident medical inspectors at Central American fruit ports: Dr. J. S. Allison, Belize, British Honduras; Dr. D. P. Albers, Livingston, Guatemala; Dr. P. R. Outlaw, Port Barrios, Guatemala; Dr. Percy Ahrons, La Ceiba, Spanish Honduras; Dr. King Holt, Bluefields, Nicaragua; Dr. Ed. B. Preis, Port Cortez, Spanish Honduras; Dr. Allen Jumel, Port Limon, Costa Rica; Dr. L. A. Wailes, Bocas del Toro, United States of Columbia.

Changes in the Medical Corps of the Navy for Week Ending May 4, 1901:

ASSISTANT SURGEON B. L. WRIGHT, ordered to the Massachusetts, May 1st.

ASSISTANT SURGEON S. S. RODMAN, detached from the Adams, and ordered to the Albatross, May 11th.

SURGEON H. L. LAW, retired, detached from the Recruiting Rendezvous, Buffalo, N. Y., and ordered home.

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine Hospital Service for the 7 days ended May 2, 1901:

D. A. CARMICHAEL, surgeon, to assume temporary command of the San Francisco quarantine station—April 27, 1901.

C. P. WERTENBAKER, passed assistant surgeon, to proceed to Prescott, Arkansas, for special temporary duty—April 27, 1901.

J. B. GREENE, passed assistant surgeon, detailed for temporary duty in the Bureau—April 29, 1901.

V. G. HEISER, assistant surgeon, to proceed to Norfolk, Va., for special temporary duty—April 27, 1901.

To proceed to Quebec, Canada, and report to the United States Commissioner of Immigration for duty—May 1, 1901.

W. F. Schlaar, hospital steward, granted leave of absence for 26 days—March 29, 1901.

Preliminary Program of the International Association of Railway Surgeons.

Mr. Hutton Crater, Kansas City, Mo., "The Relation of the Surgeon to the Claim Department."

Dr. J. L. Salmon, Ashland, Ky., "Physical Examination of Railway Employees." Synopsis: I. Physical Requirements of Railroad Labor. II. Railway Accidents; How Caused. III. Advantages of Physical Examination (a) to the public, (b) to railway companies, (c) to railway employees. IV. Alleged Disadvantages. V. Mode of Conducting Examinations.

Dr. H. A. Lippman, Burlington, Iowa, "Description of a Passenger Wreck and its Management."

Synopsis: The accident; course pursued by the operating department; first aids; temporary management by surgeons; methods of examining injured; systematic summary of injuries; results; subsequent history; conclusions; advantages of hospital facilities; remote consequences, alleged and real.

Dr. N. J. Pettijohn, Kansas City, Mo., "Fractures of Phalanges."

Dr. J. B. Murphy, Chicago, Ill., "Non-union of Fractures, Cause and Treatment."

Dr. Ben Thompson, Tama, Iowa, "Transverse Myelitis."

Dr. W. N. Middleton, Davenport, Iowa, "Abdominal Contusions."

Dr. Geo. F. Bousley, Lafayette, Ind., "Should Chemical Antiseptics be Used in Recent Wounds? When, What, How?"

Dr. G. G. Cottam, Rock Rapids, Iowa, "The Immediate Treatment of Open Fractures of the Skull."
Dr. Arthur D. Bevan, Chicago, Ill., "The Use of X-Rays in Fractures."
Dr. A. F. Jonas, Omaha, Neb., "Under Symposium on Fractures."
Dr. D. Maclean, Detroit, Mich., "Fractures—Simple, Compound, Comminuted and Ununited; Diagnosis, Pathology, Prognosis and Treatment."
Dr. G. W. Cale, Jr., Springfield, Mo., "A New and Rapid Method of Making Finished Radiographs."
Dr. O. Johnson, "Rare Fractures of Upper Extremity with Unusual Complications, and Synopsis of a Few Special Cases."
Dr. W. B. Outten, St. Louis, Mo., "The Most Frequent Fractures Met with in Railway Accidents. Based on a Series of 50,000 Personal Cases."

American Pediatric Society.—Papers to be read at the Thirteenth Annual Meeting of the American Pediatric Society, to be held at Niagara Falls, New York, May 27, 28 and 29, 1901:

1. President's Address—William D. Booker, M. D., Baltimore.
 2. "The Visceral Lesion of the Erythema Group of Skin Diseases in Young Children."
"Congenital Absence of the Abdominal Muscles with Distended and Hypertrophied Urinary Bladder in a Child of Six Years," by Wm. Osler, M. D., Baltimore.
 3. "The Feeding of an Incubator Baby," by Chas. W. Townsend, M. D., Boston.
 4. "Glass Sun Rooms on City Roofs, or Winter Playhouses" (Illustrations), by W. P. Northrup, M. D., New York.
 5. "An Account of an Epidemic of Malaria in Children," by Rowland G. Freeman, M. D., New York.
 6. "An Analysis of 32 Cases of Congenital Heart Disease," by John Lovett Morse, M. D., Boston.
 7. "A Study of 571 Cases of Summer Diarrhea," by Chas. Gilmore Kerley, M. D., New York.
 8. "A Note on the Little Finger of the Mongolian Imbecile and of Normal Children," by J. Park West, M. D., Bellaire, O.
 9. "A Case of Pulmonary Gangrene in a Baby," by Walter Lester Carr, M. D., New York.
 10. "Bulbar Symptoms in the Newly Born," by Irving M. Snow, M. D., Buffalo.
 11. "A Case of Acute Hemorrhagic Nephritis complicating Influenza in a thirteen-months-old Baby," by D. J. Milton Miller, M. D., Philadelphia.
 12. (a) "Amaurotic Family Idiocy," (b) "Monster," by A. C. Cotton, M. D., Chicago.
 13. "Cyclical Albuminuria," with report of a case, by Frank Spooner Churchill, M. D., Chicago.
 14. (a) "Heart Leap," (b) "Maternal Impressions" (report of case), by B. K. Rachford, M. D., Cincinnati.
 15. "Measles Complicated by Appendicitis," by Harold Williams, M. D., Boston.
 16. "The Treatment of Tuberculosis," by B. K. Rachford, M. D., Cincinnati.
 17. Title to be announced, F. Huber, M. D., New York.
 18. Title to be announced, A. Seibert, M. D., New York.
- Papers are promised by Doctors Rotch, Acker, Adams and others.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, U. S. Marine Hospital Service, during the week ending May 3, 1901:

MISCELLANY.

The Association of American Physicians.—Washington, D. C., April 30, May 1 and 2, 1901—First Day, morning.—The meeting was called to order at 11 A. M., the President, William H. Welch, of Baltimore, in the chair.

In the President's address, Dr. Welch compared the opportunities enjoyed in this country by the men who desire to study the branches of scientific medicine and the opportunities open to those who desire to become proficient in clinical medicine and surgery. There are laboratories in this country that are equal to any in the world that are open to young men who have graduated and who wish to become teachers of anatomy, physiology or pathology. In these laboratories a young man must serve his apprenticeship, but his promotion is sure. In clinical medicine and in surgery, on the other hand, the only way open to men who desire to become teachers of these branches is through dispensary work and private practice. The facilities at the disposal of those who desire to work in the practical branches, then, are not so good as the facilities at the disposal of those who desire to devote their life-work to the branches of scientific medicine. In other words, the training of physicians has not kept pace with the training of scientists. Dr. Welch referred in a feeling manner to the unusually large number of deaths that had occurred among the members of the association during the past year. Of the 4 members who had died, all were founders and 3 were ex-presidents. He read brief biographical sketches of Dr. James T. Whittaker, Dr. Jacob M. DaCosta, Dr. Samuel C. Busey and Dr. William H. Draper. All of these men belonged to the group of humanists who were known by the members of the association, as well as to the public, by their interest in the advancement of the human race.

Hobart A. Hare, of Philadelphia, read a paper entitled an undescribed cardiac sound. The sound referred to by the reader is a peculiar vibrating, systolic sound that is often heard by him on the level of the nipple in an area extending from one inch to the right to one inch to the left of the sternum. The sound is dry and is like a pericardial friction sound, but it is not a friction and is believed by the author to be due to a vibration of the chordae tendineae dependent upon deficient contraction of the papillary muscles. The sound has been heard in patients who were suffering from debilitating diseases. For example, it is heard in the early stages of pulmonary tuberculosis and in the patients who suffer from the anemia of influenza. It is not a hemic murmur, and, in fact, is not a murmur in the ordinary acceptance of the term, but is a vibration. It is accentuated by nervousness, but not by exercise. It resembles the word "ching" as nearly as any word. Patients who have a shallow chest, and in whom the heart is acting rapidly, present the sound. There are no subjective cardiac symptoms. William Osler, of Baltimore, said that in cases of weak heart he had heard a sound at the apex like the sound of pericardial friction, but having a more grating character. He had also heard a sound which as auscultation in the neighborhood of the sternum was done because of a crunching character. One of these sounds may be the one referred to by Dr. Hare.

William S. Thayer, of Baltimore, read a paper entitled **the frequency and the diagnosis of the Flint murmur in aortic insufficiency**. During the last 11 years the author has studied the cases occurring in the Johns Hopkins Hospital that presented the Flint murmur. During that period 74 cases of aortic insufficiency were treated, in 45 of which the Flint murmur was heard. In 12 of these 45 cases mitral stenosis was also present at autopsy, in 17 cases the mitral valve was normal, and in other cases various changes in the mitral leaflets were found. The writer is of the opinion that disease of the mitral valve, other than stenosis, can play no part in the production of a presystolic murmur. The Flint murmur is not so harsh nor so intense as the murmur of mitral stenosis. The thrill is both less frequent and less intense with the Flint murmur. In cases of aortic insufficiency, accompanied by Flint murmur, the systolic impulse is not of the tapping character noted in cases of mitral obstruction; and the snapping, valvular character of the first sound is rare. In cases that present the Flint murmur, signs that point to the existence of endocarditis are rare, and evidence of arterio sclerosis is common. The anatomical change in the aortic valves in cases that presented the Flint murmur during life are those of arteriosclerosis and present nothing characteristic. The characteristics of the pulse in cases of Flint murmur are those of aortic insufficiency. A positive diagnosis of functional presystolic murmur is difficult to make. The diagnosis is made with a fair degree of accuracy, in a patient who is without rheumatic history, who has a full, sudden pulse, and in whom the other signs of aortic insufficiency are present. The murmur is common, since it occurred in $\frac{1}{2}$ the cases, and it may be associated with the features of true mitral obstruction. Cabot, of Boston, said that he had made autopsies on 10 cases in which the Flint murmur was present during life and in which the mitral valve was normal. In these cases the diagnosis of mitral stenosis had been made during life. This series of cases would tend to confirm Thayer's observation. James Tyson, of Philadelphia, referred to a case of aortic regurgitation in which the Flint murmur was present, and in which a loud, aortic, diastolic murmur was absent. The case presented all the signs of aortic regurgitation.

Alfred Stengel, of Philadelphia, read a paper entitled, **the causes and clinical features of right-sided cardiac hydrothorax**. It is difficult to distinguish between unilateral cardiac hydrothorax and inflammatory effusions of the pleura. The author has analyzed 100 cases of cardiac disease, in 17 of which hydrothorax was present. In 5 of these the effusion was on the right side only; in 3 it was left-sided; in 9 it was bilateral, and in 7 of these the effusion was greater in amount on the right side. In 2 of the cases of bilateral effusion the fluid made its appearance first on the right side. The greater frequency of right-sided effusion cannot be accidental. The condition may be explained by the pressure of a dilated superior vena cava on the right lymphatic duct; but this is unlikely. A more probable explanation is that the effusion is due to obstruction of the great azygos vein as it empties into the superior vena cava by the dilation of the latter vessel. Right-sided cardiac hydrothorax was always seen in cases with considerable enlargement of the right heart, and this fact tends to confirm the opinion that the effusion is due to pressure. The anatomical relations of the azygos veins explain how dilation of the right heart may compress the larger vessel, while the 2 smaller azygos veins of the left side are not involved by the process. The secondary development of left-sided effusion is to be explained by back flow into the vena azygos minor. William Osler, of Baltimore, said that the history of cases of right-sided hydrothorax indicates a local cause. The condition almost always develops in cases of mitral disease. J. C. Wilson, of Philadelphia, said that in general edema, such as from renal disease, the volume of pleural effusion is usually greater on the right side. In such cases the heart is almost always enlarged, and consequently the space in the left side of the chest occupied by the enlarged heart would tend to prevent fluid from accumulating in the left pleural cavity. E. G. Janeway, of New York, said that right-sided hydrothorax is an accompaniment of weak heart as well as of valvular disease. He cited a case in which, at autopsy, there was no valvulitis, but in which there was extensive fibromyocarditis and thrombosis. H. A. Hare, of Philadelphia, said that it would be well to take into consideration the movements of the heart, which might serve to urge

on the fluids of the left side, without affecting the fluids of the right side. He described as illustrative case. A. Jacobi, of New York, said that in his opinion the likelihood of myocarditis was too frequently neglected in the consideration of the possibilities of a case of heart disease. Many cases that present symptoms of valvular disease are, in reality, muscular. Muscular lesions, as is well known, result early in the production of edema. The myocarditis may be local, and then the lesion is very likely to be overlooked. Alfred Stengel, of Philadelphia, referred to a case in his series that shows that weak heart may be the exciting cause of the effusion. In this case the hydrothorax was the beginning, clinically, of the condition. Evidences of valvular disease developed, but disappeared under treatment.

Beverly Robinson, of New York, read a paper entitled, **myocarditis and fatty degeneration of the heart**. The author finds that in cases of anemia, gouty heart and obesity, fatty degeneration is a common and a serious occurrence. In obese women, particularly, this tendency toward fatty change in the heart should make the physician cautious in advising operation, and if operation is deemed justifiable, the anesthetic should be administered with great care.

Dr. A. Jacobi, of New York, read a paper entitled, **hemorrhage into the pleura, from a pyothorax**. The patient was a boy, aged 9 years, who had suffered for a month with languor, fever, emaciation, cough and pain in the right chest. The temperature was 102°; the respiration was 40 per minute and the pulse, 140. There was dullness over the upper and flatness over the lower portion of the right lung. Puncture of the right pleura showed the presence of pus, and the sixth rib was resected for its relief. Irrigation of the cavity brought, first, pus, then, blood-stained pus, and then, pure blood. The bleeding came from tufts of granulation tissue seen on the pulmonary pleura, which varied in size and which were quite numerous. The pleura was packed with gauze and in a few days the bleeding had ceased. There was no malignant tumor, tuberculosis was not present and there were no adhesions. The recovery, which was complete, was retarded by the slowness of the expansion of the lung.

Dr. Jacobi also read the report of a case of cyst of the omentum. The patient was an Italian girl, aged 7 years, who had suffered for 4 years with swelling of the abdomen and emaciation. The abdomen was tapped and 2 quarts of blood-stained serum were withdrawn and the condition was apparently cured. Two years later the swelling again appeared and the patient was again tapped and again cure was apparently obtained. The swelling returned a second time, however, and tapping was unsuccessful because the trocar was obstructed. At operation, after the swelling had returned to its usual size, a thin-walled, multilocular cyst was found attached to the great omentum. The cyst was removed and 2 days later the temperature rose and cough developed. This accident, however, did not retard the recovery, which was complete. The specimen, which was exhibited, was a multilocular cyst cavity. The walls were lined by endothelial cells and it originally contained a gelatinous substance. The author is of the opinion that cyst is composed of dilated lymph-vessels. He is of the opinion that serous cysts, which are sometimes found, are probably chylous cysts of long standing, the contents of which have become converted into serous fluid. Kinnicut, of New York, referred to a case of acute lobar pneumonia which was followed by effusion. Aspiration of the effusion withdrew almost pure blood. Later aspiration withdrew a sero-sanguinolent fluid, and still later the fluid became serous. The pneumococcus was obtained in the fluid from the second tapping and the subsequent history of the case was not tuberculous. It is possible that the patient had a tuberculous affection of the pleura that produced the bloody effusion. F. P. Henry, of Philadelphia, said that he doubted whether tuberculosis had a causative relation to hemorrhagic pleurisy, since the majority of pleural effusions are tuberculous and since hemorrhagic pleurisy is rare. The only cases of hemorrhagic pleuritis that he had seen were due to scorbutus. Peabody, of New York, said that many cases of hemorrhagic pleuritis get well and no tuberculous symptoms subsequently develop. He also is skeptical as to the tuberculous origin of hemorrhagic pleuritis. F. H. Shattuck, of Boston, said that cases of hemorrhagic pleurisy undoubtedly recover but he would not agree that recovery from such a

condition excluded tuberculosis. F. P. Henry, of Philadelphia, said that tuberculosis of the serous membranes is more benign than in other situations. He holds that hemorrhagic pleuritis is not common. William Osler, of Baltimore, said that only one variety of tuberculous pleuritis was liable to be hemorrhagic and that is the variety accompanied by fresh tubercles and by fresh exudate. Such cases are seen in the terminal forms of acute miliary tuberculosis. A. Jacobi said that the case was reported as one of hemorrhage into the pleural sac. He brings it forward as additional cause of hemorrhage into the pleural cavity to those already so well known.

Charles Cary, of Buffalo, read a paper entitled a case of pneumonia complicated by pseudomembranous exudate on the mucous membranes of the mouth, tongue, pharynx, nares, conjunctivae, glans penis, anus, etc., caused by the *diplococcus pneumoniae*. The patient was a boy, aged 11 years, in whom there was a membranous exudate on nearly all the exposed mucous membranes of the body. The symptoms suggested that the membrane-formation involved the entire length of the digestive tract as well as the pleurae. The *diplococcus pneumoniae* was present in the sputum and in the membrane. The bacillus diphtheriae and the streptococcus was absent. After the exudate was peeled off the underlying surface was granular and bled freely. There was a leukocytosis. The patient recovered after an illness of 3 months. [J. M. S.]

First Day, Afternoon.—F. P. Henry, of Philadelphia, read a paper entitled further notes of a case of pernicious anemia reported at the meeting of 1900. The author referred to a case reported by him at the meeting last year. The patient had been suffering from pernicious anemia for 6 years. During that time he had had several slight and 2 severe relapses. There were gastro-intestinal symptoms, low red corpuscle count, relatively high hemoglobin percentage, hypoleukocytosis and poikilocytosis. At the time the report was made the patient considered himself well. This year the patient is profoundly anemic; his red cells number 1,240,000; the hemoglobin percentage is 32; the leukocytes number 3,000. There is poikilocytosis and the presence of megaloblasts and normoblasts. The patient had an attack of erysipelas during the year, but he is improving again under iron and arsenic. The author believes that the presence of megaloblasts is not the sole criterion of the existence of progressive pernicious anemia and that there are symptoms that distinguish this from other diseases whether the cells mentioned are present or not. Megaloblasts are found in leukemia, in Bothriocephalus anemia, in carcinoma ventriculi and in syphilis. The diagnosis of the disease is best made by the aggregate of the symptoms and the appearance of the patient.

Frank Billings, of Chicago, read a paper entitled report of progress of cases of pernicious anemia presented to the association in 1900 and a report of a case of pernicious anemia with diffuse spinal cord lesions with post-mortem findings. Of the 20 cases of pernicious anemia reported last year 10 were living when the report was made. Of these 10, 4 died during the year, 4 are still living, and 2 have passed from observation. One of the patients who died in February, 1901, presented a sudden accession of nucleated red cells just before death, and a diminution of leukocytes instead of the usual increase. Of the 4 patients who are still living one is still improving. The color index remains high, however, during the period of improvement. One patient had an improvement wave of nearly a year's duration. The author has seen 9 new cases during the year, of which 7 are males and 2 are females. He has adopted a method of estimating the volume index of the blood. He estimates the percentage of red cells with the hematokrit and counts them with the hemocytometer. He then makes a fraction the numerator of which is the percentage by the hematokrit estimation and the denominator of which is the percentage by the hemocytometer. The result of the division gives the volume index. One of the patients who died was a woman, aged 36 years. She had had gastro-intestinal symptoms, menstruation had ceased, she was anemic, with lemon-yellow color of the skin and loss of control of bladder and bowels. There were no carious teeth, the lungs were negative, there was a soft systolic murmur at the base of the heart and visceral ptosis. The patient died on an improvement wave, with terminal leukocytosis, paraplegia and sensory phenomena. The immediate cause of death was an ascending infection of the genito-urinary tract from infection of the bladder, over which control had been lost.

At autopsy, important changes were found in the spinal cord. In the lumbar region, the posterior columns were sclerosed and the lateral pyramidal tract was also degenerated. In the cervical region, these columns were degenerated as well as the anterior pyramidal tract and Gower's tract. James J. Putnam, of Boston, said that it is an open question whether the spinal cord lesions were pathognomonic or whether they are similar to those seen in other diseases. They are certainly not due to the anemia as such. They are similar to the lesions seen in diseases characterized by changes in nutrition. William Osler, of Baltimore, said that there is a group of cases of pernicious anemia in which the anemia occurs after the onset of the spinal symptoms which needs full clinico-pathological study in this country. McPhedran, of Toronto, said that he had seen such a case as referred to by Osler in which the blood did not show the changes of pernicious anemia. F. H. Shattuck, of Boston, referred to a case of pernicious anemia following mental shock. John H. Musser, of Philadelphia, said that he had had a patient under observation since 1896 who presented the clinical picture of locomotor ataxia and whose blood was a typical picture of that of pernicious anemia. In this patient the nervous symptoms developed first. Blood examination showed hemoglobin, 50%; red corpuscles, 1,500,000; white corpuscles, 45,000; myelocytes, poikilocytes, megaloblasts and microcytes. There were no normoblasts, however, and the color index was high. He said that many patients with pernicious anemia were sent to hospital with diagnosis carcinoma of the stomach, gastric catarrh, carcinoma of the liver, heart disease and tuberculosis. Frank Billings, of Chicago, called attention to the fact that the degenerated tracts in his case of spinal cord lesion were not shrunken.

David D. Stewart, of Philadelphia, read a paper entitled acute miliary tuberculosis, primarily splenic. The patient was a nurse, aged 29 years, in whom there was no tuberculous history. Four weeks before she was admitted to hospital she had had an attack of influenza and before she had recovered from that attack she took charge of a case of tuberculosis. On admission, she was suffering from chills and fever, debility, and pain in the dorsal region. She died on the sixty-eighth day of her illness. During life the spleen was enlarged and extended from the sixth interspace to below the costal margin. Two weeks before death, enlarged glands developed in the supraclavicular fossa. At autopsy, tuberculosis of the lungs, the liver, the kidneys and the membranes of the brain was found, the existence of which was not indicated by clinical signs during life. The spleen was full of tubercles, some of which had advanced to complete caseation. The infection was apparently from the tuberculous patient whom she had nursed.

John H. Musser, of Philadelphia, read a paper entitled notes on relapsing fever in Hodgkin's disease. The patient was a man who had been ill 5 months before admission to hospital and who presented hemorrhage from the nose, enlarged spleen and general lymph-node enlargement. He had recurrent attacks of fever accompanied by acute enlargement of the lymph-nodes and jaundice. The patient died 1 month after admission and during that time treatment had no effect on the course of the febrile attacks. There was a febrile period of 6 days, then a period of apyrexia of 9 days, febrile period 9 days, apyrexia 11 days, fever 8 days, apyrexia 11 days, fever 10 days and death from exhaustion. In a second patient, a man, aged 53 years, who was under observation for 3 years there was a family history of tuberculosis. The patient, however, was a man of correct habits. He had moderate anemia which became more marked and progressive and there was the appearance and the disappearance of enlarged glands with the attacks and remissions in the fever. Enlarged spleen was also present. There was a febrile period of 12 days, then a period of apyrexia of 10 days, fever for 9 days, apyrexia 6 days, fever 8 days, apyrexia 15 days, fever 8 days, apyrexia 8 days, fever 8 days and then the fever became continuous on account of the development of pleuritis with effusion. During the course of the disease the patient began to cough but once only was the sputum found to contain the tubercle bacillus. Before the occurrence of a febrile attack the patient became irritable and had pain in the inguinal lymph-nodes and loss of appetite. During the febrile paroxysms insomnia was a very annoying symptom. The pleural effusion was sterile by cultural and inoculation tests. Blood from the patient was injected into a rabbit and the animal died from the development of lymphomata on the lungs. Wil-

ham H. Welch, of Baltimore, said that in many cases the fever of Hodgkin's disease had been shown to be due to tuberculosis. John H. Musser, of Philadelphia, said that he believed that in the cases reported the fever was probably due to the development of tuberculosis.

Alfred Stengel, of Philadelphia, read a paper for C. Y. White and William Pepper, of Philadelphia, entitled a **study of granular degeneration of the red blood corpuscles**. The reader referred to cases of chronic lead poisoning in which a granular degeneration of the red cells was noted. The granules were small and were evenly distributed throughout the cell in some cases, or had a tendency to clumping in others. The granules show a different affinity for certain basic stains. They may be found in normal cells, in poikilocytes or in nucleated cells. The granules are not detected in fresh or dried specimens. The condition is not due to karyorrhexis, but is probably due to some chronic blood poisoning. They were experimentally produced by Grawitz in early lead poisoning in mice. The authors have studied the condition in lead workers, in patients suffering from chronic lead poisoning, in cases of patients exposed to high temperatures, and experimentally in poisoning animals with lead. In 4 cases of lead poisoning the granules were present in all; in 21 lead workers, with no symptoms of lead poisoning, the granules were present in all. In 4 individuals who worked in front of furnaces and in 4 patients treated by the local application of superheated air only one presented the change. The granules appeared in dogs, in which small doses of acetate of lead were administered, in 24 hours. The splenic vein contained the greatest number of corpuscles affected by this degeneration. This granular degeneration, then, is a constant finding in lead poisoning; they disappear from the blood as convalescence progresses; there is no immunity. The granules are a true degenerative product. A. Jacobi, of New York, asked of what significance the granules were? He is in the habit of giving large doses of acetate of lead at times. David H. Stewart, of Philadelphia, said that it appeared to him that the granules might be an important diagnostic sign of lead poisoning, and that they might be called a symptom of lead poisoning. Alfred Stengel, of Philadelphia, said that the patients in whom these granules were found had also nucleated red cells and poikilocytes. In other words, they were actually poisoned by lead, but without symptoms. diagnostic sign of lead poisoning. Alfred Stengel, of Philadelphia, said that the patients in whom these granules were found had also nucleated red cells and poikilocytes. In other words, they were actually poisoned by lead, but without symptoms.

(To be Continued.)

30TH CONGRESS OF THE GERMAN SURGICAL SOCIETY.

(From our Special Correspondent.)

(Continued.)

5th Session.—On Wednesday evening a number of demonstrations of photographs, skiagraphs, etc., were given.

Gobel of Ruhrort reported a case of resection of the lung similar to Heidenhain's case. Sarfert of Berlin treats of "The operative treatment of tuberculosis of the lung." Kuster of Marburg demonstrates photographs showing his method of rhinoplasty. Paper of Graz "Conservative operations on the testis and the epididymis." Paper reports the case of a patient with acute orchitis following gonorrhea. Paper incised and opened an abscess, but gangrene followed, and he was compelled to castrate. Two years later an acute orchitis of the remaining testis appeared, and Paper again performed a conservative operation incising the albuginea and opening an abscess; this time he succeeded in saving the testis, and has demonstrated living spermatozoa in the patients semen. Bessel-Hagen of Charlottenburg described a plastic operation for complete loss of the skin of the penis and scrotum. He first healed the penis under the skin of the abdomen, then formed two skin flaps at the side of the penis, and closed them over the dorsum of the penis, in much the same way as Senn operated some years ago, an operation apparently unknown to Bessel-Hagen. v. Mikulicz of Breslau "The different methods of anesthesia and their indication." He has been collecting information bearing on the question,

which of all the narcotics is the least dangerous, and has arrived at the conclusion that it is not a question whether one should narcotize with chloroform or with ether, but when one should use chloroform and when ether. The question whether one should use inhalation anesthesia at all has been actively discussed of late years since the introduction of local anesthesia. v. Mikulicz then gives a chronological review of the methods of local anesthesia; the freezing method, cocain injection, Schleich, Oberst's and Bier's methods. He has used lumbar anesthesia in 40 cases with startling results, and considers it the method of the future, although not yet sufficiently perfected to be introduced into general practice. He has lost no case, but has experienced some very unpleasant after effects. The statistics of narcosis and of local anesthesia show that the former is still in much greater use. Local anesthesia in spite of having now such large fields of surgery is nevertheless of no value in many laparotomies, in nephrectomies, amputations of the breast, etc. There is room for question in operations on the stomach and bowels, herniotomies, and in operations for goitre. Deaths have occurred with local anesthesia. A great drawback is that the topographic relation of the parts is changed by the infiltration. One would naturally prefer local anesthesia in cases of heart and lung affections, yet the mortality of post-operative pneumonias following Schleich is still large. Much depends upon the kind of operation and upon the reaction of the individual to pain. Shock can be caused by pain alone without narcosis. v. Mikulicz formerly used chloroform exclusively, now he uses ether oftener since he has learned to avoid the dangers of the ether narcosis by using the graduated method of Hoffman of Bonn. Bier of Greifswald; "Anesthesia of the Cord." Up to the present time 1200 operations have been performed with his method. After injecting one-third gr. of cocain the sense of pain is first paralysed, then the sense of heat and cold, then the sphincters; finally the anesthesia extends so high that amputations of the mamma and and resections of the ribs can be performed. Toxic effects are met with; headache, dizziness, vomiting, loss of appetite and sleep, chills, fever, sweats, disturbances of the circulation, paresis, collapse and death. Bier has consequently arrived at the conclusion that the method in its present form is useless for the practitioner. He has been trying by experiments upon animals to find a way to counteract the harmful effects of cocain. He has succeeded in obtaining anesthesia by injecting normal salt solution into the cord of cats, and thinks it was caused by pressure upon, and swelling of, the cord. He has tried further all the cocain derivatives, and diluted solutions of cocain, but succeeded in obtaining either no anesthesia at all, or only one of short duration. Tropacocain never gave good results; the diluted solutions of cocain gave an analgesia which extended over a large territory, but he never obtained anesthesia, the sense of touch and of warmth remained perfectly normal. Bier thinks it would be possible by compressing the neck with a bandage until marked cyanosis of the face appears to shut off the toxic effects from the brain. His opinion is that the method is still in the stage of development, and still far removed from general use.

Braun of Leipzig demonstrates a new apparatus for narcotizing with a mixture of chloroform and ether.

Wohlgemuth of Berlin; "A new Oxygen-chloroform Narcosis." Wohlgemuth demonstrated an apparatus consisting of a cylinder containing oxygen under a pressure which can be regulated, and so arranged that escaping oxygen passes through an automatic attachment which permits chloroform to fall in drops into the stream of gas; then the mixture is conducted into a tight-fitting mask. Wohlgemuth has tested the apparatus in 181 cases and expresses his complete satisfaction with the method, especially with its effect on the pulse. In almost all cases the pulse registered 60 beats per minute. The amount of chloroform used is small, for the longest operations not more than F.-18 grains.

6th Session. The 6th session opened with a paper

by Tilmanns of Greifswald on "Intracranial Pressure." The speaker observed two cases in which the change from the vertical to the horizontal position was immediately followed by coma; these cases led him to subject the brains of dogs to the pressure of fluids of different specific weights. Tilmanns concludes that an intracranial hemorrhage does not cause pressure by decreasing the volume of the intracranial cavity alone, but also according to the laws of gravitation.

Brann of Goettingen read an interesting paper on "The Resection of the Sympathetic in Epilepsy." Brann first describes the operations performed by Jonnesco, and expresses his surprise that Jonnesco could succeed in removing the three upper ganglia of the sympathetic, on account of the anatomical difficulties. Brann has operated in 9 cases, incising behind the sternocleido mastoid, but has found it impossible to resect the inferior ganglion. He has observed no influence on the respiration or the heart action, but has seen in each case ptosis contraction of the pupil and dilatation of the blood vessels. He has seen no change in the pulse tension; increased excretion of the sweat glands did not occur in every case. The contraction of the pupil gradually disappeared, the dilatation of the blood vessels, by which Jonnesco endeavors to explain the value of the operation in epilepsy, disappeared in the course of 24 hours. Nor does Brann believe that the dilatation of the vessels of the brain continues for any length of time. Brann lost 2 of his 9 cases, one of them in an epileptic attack following the extirpation of both nerves. The operation itself is not dangerous, but although he thought some cases improved, in no case could he report a cure.

Jordan of Heidelberg opened a large field for discussion with a paper on "The Operative Treatment of Carcinoma Uteri." Of the four methods for extirpating the uterus 2 have been completely deserted; the perineal and the sacral. Most operators now prefer the abdominal route, especially so in France. Jordan believes that the vaginal route should be followed except when extraordinary features indicate the abdominal route; he also considers it questionable whether one should extend the operation to the whole lymphatic system of the pelvis as advised by Freund. Jordan then discussed the question in relation to mortality and recurrence, using the statistics of the Heidelberg clinic; he concludes that the dissatisfaction with the vaginal route is entirely unjustified. To be sure the field of operation is better with the abdominal route; it is easier to clean out the pelvic tissues, but the same can be accomplished with the vaginal operation even if not quite so extensively. The removal of the lymphatic glands can be accomplished only by the abdominal route, against which fact Jordan places the great variability in the infection of the lymphatic glands in all classes of carcinoma uteri. It is impossible to remove the whole lymphatic system of the pelvis; his observations have taught him that the glands become first affected at a late stage, and that only in rare cases. His conclusion is, since it is impossible to remove the glands completely, and the partial removal has no object; since the danger of the extended abdominal operation is considerable; and since, finally, the percentage of lasting cures is no larger with the abdominal than with the vaginal route; therefore, the normal method is the vaginal. The fact of the cancer having attacked the bladder and the rectum is no contraindication of the vaginal route. He recommends Schuchardt's paravaginal incision and sews the anterior and posterior walls of the vagina over the portio to avoid infection.

Schuchardt of Stettin; "The Paravaginal Method for Extirpation of the Uterus and the final Results of the Method in Carcinoma uteri." Schuchardt believes that with his method the indications for extirpation of the uterus can be made much broader, and demonstrated preparations which are intended to show that one can remove the entire parametria with the aid of his incision. His mortality in all cases, both the simple and the severe cases, was 12%. The incision is of itself perfectly harmless and always heals by first intention. He has performed 60 operations in 58

cases. Of the noncomplicated cases he has obtained 88%, of the complicated cases 37%, of the severe cases 14% complete cures. If he counts only the cases operated more than 5 years since, he can show 40% lasting cures. His absolute percentage of cures is, therefore, as large again as that of other gynecologists.

Duhrssen of Berlin; "Vaginal Laparotomy as a Rival of Ventral Laparotomy, based on 874 Cases." Duhrssen's operation, colpoceliotomy anterior, has led him to abandon the abdominal route almost entirely. Even the largest tumors of the ovary can be removed with this method and their pedicles can be securely ligated. The advantages of the operation consist in the low mortality; in his last series of 374 operations, in spite of numerous difficult cases, Duhrssen has had but 2% mortality; further, in the more rapid recovery, and in the avoidance of the inconveniences and dangers following the abdominal wound. Duhrssen has operated 700 times in cases of retroflexion and retroversion; in the majority of these cases the abdominal position of the uterus was combined with various diseases of the adnexae or with chronic pelvic-peritonitis. The adhesions of the uterus and the adnexae can be separated under control of the eye by means of Duhrssen's method. Any unfavorable influence of vaginofixation on subsequent parturition can be avoided by careful suturing of the wound of the peritoneum. He has seen normal childbirths followed in 37 of his cases. In 300 cases of various inflammations and pathological growths he has removed the ovary and the tubes, leaving in each case the uterus, and at least a part of one ovary. Duhrssen has performed 200 conservative operations on the adnexae, removal of both ovaries to prevent conception in severe chronic disease, salpingostomy to make conception possible, and especially often ignipuncture or resection in cases of small cystic degenerations of the ovary, after which operations he has showed normal pregnancies. In 74 cases he has performed conservative operations on the uterus, for the most part enucleations of myoma, and in 6 cases of uncontrollable hemorrhage, excision of the mucous membrane of the uterus instead of total extirpation. In spite of this simpler technic the mortality of these operations was larger than in operations on the adnexae. Duhrssen claims that it is possible by dividing one of the broad ligaments in addition to his incision, the operation which he calls colpoceliotomy anterio-lateralis, to remove with safety the pus containing tumors of the adnexae.

Doderlein of Tuebingen; "A New Method of Performing the Total Extirpation of the Uterus through the Vagina." The new method consists in the complete division of the uterus into two halves by an incision beginning at the posterior wall of the cervix, thence into and through the uterus cavity, following the posterior wall up to the apex of the corpus and down the anterior wall; continuing the incision through the anterior wall, the operator reaches the vesico-cervical space without danger of injuring the bladder, which has been removed from the cervix by the strong downward traction on the uterus. The incision which began at the posterior lip of the cervix is completed by incising the anterior lip, and the operation is finished by extirpating each half of the uterus by itself.

Olshausen of Berlin followed with a paper on the same subject as the preceding papers. His experience has been the same as Jordan's. It has always been his opinion that one can expect a cure only when the cancer has not gone beyond the boundaries of the uterus, and he considers only such cases operable. He has never thought, and especially of late, that one should remove the lymphatic glands, even though he has extended his operation. Cancer can recur after 4 to 5 years; he has seen recurrences in 38.9% after 5 years. He believes further that the abdominal operation is only admissible where the vaginal method is technically impossible. Schuchardt's incision is necessary in only $\frac{1}{4}$ of all cases; he has seen abundant hemorrhage and cancer infection of the wound after using Schuchardt's method. Olshausen points out that the pus of a prometria is especially septic and for that reason he would con-

sider Doderlein's method applicable only to cases of beginning carcinoma, but not to cases complicated by pyometra. He does not believe in the great danger in separating adhesions of the bladder, except possibly in unusual cases, and then he doubts that Doderlein's method would give any better results.

In the discussion following these papers, Martin of Greifswald says he agrees perfectly with Jordan. He has experienced one very unpleasant hemorrhage following Schuchardt's incision, yet thinks he can recommend the method. He expresses some doubts in regard to Doderlein's method, but thinks it should be tried.

Werthheim of Vienna took the opposite view. It is his principle to operate in all cases by the abdominal route and to remove the connective tissue surrounding the uterus, and the lymphatic glands, having found in 18 out of 50 cases that the glands were affected, all of these being cases which were not far advanced. Werthheim considers it more important, however, to clean out this parametrium than to remove the glands, and he thinks this is only possible by the abdominal route. His results were at first unfavorable, losing 11 out of 33 cases. He thinks now that he then went too far. Of his last 20 cases he has lost but 3, 2 from necrosis of the ureters, and one from metastasis in the liver. The future will show the superiority of the abdominal method.

Kummell of Hamburg mentioned those hopeless cases in which one must operate to relieve complications. In three cases of closure of the ureters he has resected the ureters and sewed them into the bladder.

Frund of Strassburg emphasizes that statistics can only be of value when one and the same operator uses one and the same operation in all his cases. He considers the vaginal operation merely palliative. The abdominal method is indicated in all earlier cases where there is any hope of success.

Petersen of Heidelberg; "The Structure, Growth and Histogenesis of Carcinoma of the Skin. Petersen has made use of the embryological method (after Born and Strasser) of plate models in wax in the study of cancer. He believes that the study of such magnified serial sections, besides being of great value to the teacher, proves that skin cancer propagates itself in two ways, unicentric, starting from one single center and spreading into the neighboring tissues, and multicentric, beginning at several points independently. The masses of epithelial cells which grow from each independent focus, spread by sending branches into the tissue; the so-called cancer alveoli are in the majority of cases merely cross sections of such branches of the main growth. Petersen believes this study of such serial reconstructions teaches that the growth of the epithelium is the primary factor in the histogenesis of carcinoma, as opposed to Ribber's theory of the primary growth of the connective tissue.

Kossmann of Berlin; "The Origin of Carcinoma, especially in the Ovary." Kossmann showed micro-photographs of a "cancer" of the ovary which contained both cylindrical and pavement epithelium, and considers it an impossibility to assume that a parasite could cause the growths of such widely different kinds of epithelium. He would therefore hold to the theory of Connheim that the cells had become dislocated from their normal position at some period.

Ehrhardt of Koenigsberg advised the use of boiling water instead of the paquin to destroy any remains of a tumor in the wound, to guard against transplantation. In the general discussion Gussenbauer of Vienna considers Petersen's method too schematic. v. Hausemann points out that we cannot call such models diagrams and that they are of great value in the study of the histo-morphology of cancer. Israel, v. Kahlden, Heidenhain and Petersen took part in the discussion. Hollander of Berlin presented a case of carcinoma of the nose; the patient has now multiple carcinoids on her whole body.

Kronlein of Zuerich; "Is Narcosis advisable in Resection of the Upper Jaw or not?" Kronlein demonstrated in a

table that the earliest recorded cases of this operation showed a better mortality than the operations performed since antiseptic and aseptic times. He concludes, therefore, that some further factor must enter into the question. This factor is the narcosis, a belief supported by the result of Koenig and Kuster. Both of these authors owe the half of their lost cases to bronchopneumonia following aspiration of the blood. This danger cannot be avoided by partial narcosis, and so Kronlein operates with almost no narcosis. He has lost but one of his 35 patients, and this one died of meningitis.

Wohlhardt of Halle; "The Disappearance of the Toxicity of Cocain in the Animal Body." The author has found that a lethal dose of cocain injected into a rabbit's leg and prevented from entering the general circulation by a rubber bandage, produced no, or only slight toxic symptoms after removal of the bandage $\frac{1}{2}$ to 1 hour after the injection; he concludes that the cocain must have lost its toxic properties. Discussion: Schwarz of Agram; "Lumbar Anesthesia," claims that tropacocain is superior to cocain in its after effects; in 44 cases he has seen headache in but 4 cases, in no case nausea or rise of temperature. Blau of Tuebingen demonstrated blood pressure curves and showed that the blood pressure rises under ether and sinks under chloroform. Riedel of Jena fears the aspiration of blood, and operates in all cases on the mouth easily, etc., with the lead hanging below the horizontal. Kader of Breslau reported favorable results in 56 cases of lumbar anesthesia. He gives digitalis for one or two days before operation, and uses camphor if any heart symptoms appear. Gussenbauer of Vienna uses complete narcosis in resections of the jaw, and operates with the head held forward. He has had to perform tracheotomy in consequence of aspiration of blood in 2 cases, both of which recovered.

19TH GERMAN CONGRESS FOR INTERNAL MEDICINE.

Held at Berlin, April 16th-19th, 1901.

The annual German Congress for Internal Medicine which meets alternately at Berlin and Wiesbaden, assembled for its 19th session in the Architekten-Haus, Wilhelmstrasse, Berlin, on April 15th, 1901. The usual exposition accompanying the congress was devoted this year especially to instruments, etc., designed as aids in diagnosis; an extraordinary feature was the large and richly illustrated volume prepared under the direction of Mendelsohn of Berlin "The Development of Apparatus for Clinical Diagnosis," which was presented to each member of the congress. This volume gives a short description by men of note in their various lines of work, of the numerous mechanical, optical and electrical aids in clinical diagnosis.

The President, Senator of Berlin, paid especial attention to his address opening the congress, to the progress made in the diagnosis of internal disease during the past century. Senator described in a brief historical sketch the gradual development from pure empiricism, through the reactionary,—the nihilistic period when the physician doubted his ability to influence disease—to the present period when internal medicine, firmly footed on the foundation built by the pathologists; notably Brichat, Rokitsky and Virchow, began its scientific career, a period to be best judged by its results. The chief results have been in diagnosis. Here is to be especially noted the modern treatment of tuberculosis, and serum therapy. Truer today than ever before is the old saying, "*qui bene diagnost, bene curat.*"

The congress was then greeted by the representatives of the Austrian Ministry for Education, von Jakseh of Vienna, and of the Prussian Ministry, Pistor of Berlin, and by the representatives of the city of Berlin, etc.

The work of the congress then began with the first main topic of the program, "Heart Stimulants and Vasomotor Stimulants?" Gottlieb of Heidelberg treated the subject from the experimental standpoint. He described first, the conditions in which vasomotor stimulants are indicated.

In the case of paralysis of the vasomotor nerves due to some influence upon the vasomotor center, such as the narcotic poisons, or in the course of acute infectious disease, blood vessels of the abdomen become congested and anemia of the vessels of the periphery and of the brain results; the pulse becomes small, the heart chambers are poorly filled; but this not because the heart lacks the power to do the work, but because it lacks material with which to work; the blood is retained in the congested vessels of the abdomen. In these conditions the vasomotor stimulants by causing contraction of the blood vessels controlled by the splanchnicus, bring the distribution of the blood back to the normal, relieve the anemia, and enable the heart to fulfill its function. The oldest of these vasomotor stimulants is strychnin; caffeine is preferably because of the tendency of strychnin to produce convulsions. Camphor also acts in the same way as strychnin and caffeine; another vasomotor stimulant is the local application of cold. It is to be noted that only the blood vessels which are controlled by the splanchnicus are affected by these drugs. They also affect the respiration. Ether and alcohol have no tonic effect, but on the contrary a dilating effect upon the vasomotors. Heart stimulants increase the functional activity of the heart by increasing the volume of the heart stroke, thus relieving the pathological distribution of the blood which follows heart lesions as well as abnormal innervation of the blood vessels. The therapeutic value of digitalis is to be sought in this increase of the functional power of the heart; its effect is always on the action of the heart, never on the organic lesion. The constriction of the blood vessels caused by digitalis is of but secondary therapeutic importance. Gottlieb described experiments on the heart of the higher vertebrates, using a modification of the method of Hering and Bock on the heart of the living animal, and the method of Langerdorff on the isolated heart. Gottlieb and Magnus have further studied the heart action by introducing a rubber balloon into the heart chambers, inflating the same, and registering the degree of systolic compression of the balloon. They have found that the work done by the auricle is increased three or four fold after giving digitoxin. The increase is due to a stronger systolic contraction of the heart muscle. This increase of the functional power of the organ is of especial significance in valve lesions. This lessening of the frequency of the heart beat which follows the use of digitalis, caused by stimulation of the vagus is also of no little therapeutic value. The complete therapeutic action of digitalis is therefore attained in this stage when the lessened frequency of the beat permits complete diastolic expansion and filling, and the strengthened systole brings a more complete emptying of the organ. All drugs containing digitalis cause contraction of the blood vessels; this effect is, however, of but secondary therapeutic value, for example in aiding to overcome the congestion of the vessels of the abdomen. If this contraction becomes too pronounced it can be of detriment to a diseased heart by increasing the work to be done. Gottlieb's paper finished by merely touching upon the other important heart stimulants. Camphor influences the heart indirectly by its stimulative action on the vasomotors, but also directly by making the heart itself more susceptible to stimulation. Caffeine has a direct effect on the heart by increasing the power of the organ to overcome pathological difficulties. Caffeine does not affect a healthy heart if the pulse tension remains normal. Gottlieb notes the elective action of theobromin upon the coronary vessels and the consequent value of the drug in angina pectoris. Alcohol influences the heart indirectly by causing dilatation of the blood vessels, thus decreasing the difficulties to be overcome, in cases for example where the pulse tension is too high. Gottlieb expresses the hope that pharmacology and clinical experience together will in the future solve the problem of the right choice of the stimulant or combination of stimulants, in spite of the complicated mechanism which governs the heart and the vasomotor supply. Sahli of Bern treated the clinical side of

the problem of heart stimulants and vasomotor stimulants. He emphasized first that the future of internal medicine is to be sought in the advancement of functional diagnosis; the search after a specific treatment leads us too far into the future. His paper began with a discussion of the pathology of the circulatory disturbances. Sahli divided the congestions into three groups whose common characteristic is in the slowing of the aortic blood stream and the pathological distribution of the blood: (1) The cardiac congestions due to insufficiency of the systole, or to mechanical prevention of the diastole. (2) Respiratory congestions in diseases of the respiratory organs, or due to intrathoracic exudations; Sahli considers the congestions of this group due indirectly to cardiac congestion. (3) Vasomotor, better, vasodilator congestions, caused by paralysis of the small vessels of the body. Sahli divides the cardiac congestions into high tension and low tension congestions. A further group form the congestions in the vessels controlled by the splanchnicus, congestions caused by heart lesions and by primary vasodilatation. Sahli then emphasized the necessity of diagnosing these congestions in their early stages, and advised the practitioner to begin treatment much earlier than is usually the case. He believes that digitalis is useful in all these forms of congestion; but the physician must avoid schematic treatment, and must know when further therapeutic measures should be added to the digitalis treatment. In congestion with high tension pulse Sahli has found that digitalis is by no means contraindicated, but that it may even lessen the pulse tension. The success of the digitalis treatment is the explanation of the fact that digitalis may effect a cure which may last for years after one has stopped treatment, is the interruption of the *circulus vitiosus* by the drug; the heart itself suffering from the congestion, regains normal circulation in the coronary vessels, and can hold its own again. Sahli then discusses those cases in which digitalis gives no results, cases which he would call essential congestion. By this term he designates those cases where the valve lesion has become so pronounced that it is mechanically impossible to avoid congestion even with normal heart power and normal systole. In such cases digitalis treatment is either of no value, or else merely transitory value. Sahli's opinion is that there is no difference in the action of digitalis on any of the valve lesions. The claim that the drug has no effect in insufficiency of the aorta he explains by the fact that these cases first come under treatment after the lesion has existed for years and the congestion has become "essential." In regard to the dose Sahli pointed out the difference in the principle of large doses and of small doses; large doses affect both systole and diastole, small doses the systole alone. In regard to the long continued use of the drug, to its cumulative action, and to the patients becoming accustomed to digitalis, Sahli agreed with Grodel and Kussmaul. Caffeine and camphor act in an entirely different manner from digitalis. Their stimulative effect on the heart is confined to the systole. Their chief value is in their action on the vasomotors. The action of caffeine and camphor on the respiration and the diuretic action of caffeine are advantages not to be overlooked. There is no direct proof of a direct action of alcohol on the heart. In cases of high tension it can be of value by diminishing the tension and thus aiding to cardiotonic drugs. Its effect is too transitory to make alcohol of value when used exclusively in cases of high tension. Sahli considers alcohol contraindicated in the acute infectious diseases because it acts in the same way as the toxins themselves. Alcohol is useful as a transitory stimulant in chills, etc. Neither alcohol nor ether are indicated in all cases of collapse. In closing Sahli emphasized the importance of the right choice of the drug or combinations of drugs, and noted further the complicated mechanism of the human body. Oftentimes drugs, etc., which have absolutely no direct action on the heart may be of the greatest therapeutic value.

Enteric Fever in South Africa; Effective Sterilization of Excreta. MAJOR H. A. CUMMINS.

Venesection in the Treatment of Gunshot Wounds of the Chest. CAPTAIN F. J. W. PORTER.

1.—In the Imperial Yeomanry Hospital at Pretoria, Washbourn has met with a very large number of cases of jaundice. As recovery always occurred, the pathology of this affection can only be surmised at. The nausea, vomiting and abdominal pain which accompany the disease, suggest an inflammation of the duodenum which leads to blocking of the orifice of the bile duct, and thus causes jaundice. The occurrence of jaundice in epidemic form points to some infective agency. In the cases of enteric fever which the author has observed, constipation is the rule and diarrhea and hemorrhage are uncommon. Phlebitis of very frequent occurrence, and is very much more common than in England. Patients who have been exposed to excessive fatigue, and those who have been conveyed long distances in an ambulance during the early stages of the disease frequently succumb ultimately to cardiac failure, although the attack has otherwise not been severe. From clinical observation the author is satisfied that inoculation does not modify this disease. Phlebitis has followed other conditions than typhoid fever, or has arisen without any definite cause in a number of cases. It is probable that there are several specific fevers in South Africa that have not been recognized; although they represent Malta fever more frequently than any other disease. [J. M. S.]

2.—Thomas describes the method of pitching hospital tents. He has also found that wounds inflicted by ricochet bullets are severe and that lesions of an expanding bullet are most disastrous after penetrating bone; and those of the Lee Metford and Mauser are of a comparatively trivial character. The author uses a forceps-tourniquet in all cases of amputation, and regards it as the most reliable and convenient instrument when the surgeon cannot rely upon the help of any skilled assistants to control hemorrhage. The application of the forceps-tourniquet causes the simultaneous closure of both the arteries and the veins. In the use of the telephone probe the author believes that it is more desirable to put the silver plate on the patient's tongue than to apply it as directed to the skin. Over 40% of the cases in the Welsh Hospital were surgical and there was extraordinary uniformity of healing in almost all of the cases. [J. M. S.]

3.—Watson describes the conditions pertaining at No. 6 Hospital, Johannesburg. [J. M. S.]

4.—J. W. Smith reports a number of interesting cases of gunshot wounds occurring in the war in South Africa. He reports briefly a number of cases of penetrating wound of the chest, in which it would seem most probable that the heart itself had been injured by the ball, and yet, after a few days of hemoptysis the patient recovered. He also refers to cases of penetrating wounds of the abdomen which recovered without operation. The prompt healing of wounds in other parts of the body was also surprising. Aneurysms as the result of injury to arteries are not infrequent. Injuries to nerves were more numerous than would be expected, and a number of instances are reported where operation was necessary for this condition. It is thought that where bullets lie deeply, specially in the trunk, and are causing no symptoms,

it is probably better not to disturb them. Smith found that the fractures of the long bones were generally oblique in direction, irregular and accompanied by a great deal of splintering. The wounds of the knee joint made the most surprising recoveries. What is said of the modern bullet wound cannot be said of the expanding bullet or of the shell; most of the wounds caused by the latter become infected. [J. H. G.]

6.—Alexander Ogston describes the Veld sore as a superficial infected blister closely resembling the well-known onychia occurring in mill workers. The epidermis is elevated into a semi-translucent swelling with an area of inflammation around it. Lymphatic involvement is seldom seen. This peculiar sore is only seen in South Africa; it occurs mostly on the hands and forearms and on the feet and legs. Suppuration is not a characteristic of the Veld sore, but crusts of serum are apt to form over the sore. The sore is due to a micrococcus closely resembling the gonococcus, and Ogston thinks that this organism is an inhabitant of the vegetation and soil of the Veld. [J. H. G.]

7.—W. H. Harland describes the Veld sore very much as is done in the foregoing article, but seems to have observed lymphatic involvement and fever more often than did Ogston. He has found the disease very amenable to treatment by mild antiseptics. He thinks it due to the sting of an insect. [J. H. G.]

10.—F. J. W. Porter reports an interesting case of an officer in South Africa who was shot through the chest, and who, as a result, suffered great inconvenience in respiration from a large accumulation of blood in the right pleural cavity. It was necessary to carry the patient over a number of miles of rough country. 24 hours after this injury his pulse was small and the heart's impulse diffuse. Lividity was very marked and the patient was quite delirious. At this time 10 ounces of very dark blood was drawn from the median basilic vein with the most gratifying result, the patient turning on his side and going to sleep immediately afterward. The patient was enabled to continue his journey with much less suffering, and ultimately made a good recovery. [J. H. G.]

5.—Worthington describes the conditions pertaining in the Princess Christian Hospital, South Africa. [J. M. S.]

8.—During April, May and June, 1900, there were 295 cases of enteric fever in the General Hospital in Tin Town, Ladysmith. The disease was, as a rule, of malignant type. In about 40% of cases no rash was found, and in about 20% the rose spots were thickly scattered over the trunk and extremities, whilst the remaining 40% followed the usual course. In only 5 cases out of the entire number was any diarrhea noted. As a general rule, the delirium was of the rambling or muttering type, giving rise to no anxiety and calling for no treatment. Thirty of the 295 cases had been inoculated. The complications were more numerous, the duration of the fever longer and the death rate higher in the inoculated. [J. M. S.]

9.—Cummins makes a second report on his method of sterilizing the excreta of patients suffering from typhoid fever. In 2 minutes all forms of life have become extinct, and even spores have lost their vitality. The cauldron used in his hospital has a capacity of 40 gallons. It is emptied every evening for cleansing purposes; 20 gallons of a solution of izal or crude carbolic acid in water is poured into it, and when this has been heated to near the boiling point the apparatus is again fit for use. Smell from the boiling cauldron is practically absent, and flies do not approach it. [J. M. S.]

1.—Rolleston delivered a lecture on **carcinomatous stricture of the duodenum**, at St. George's Hospital on March 11, 1901. The following history of the case is given: On November 29, 1901, a plumber, 50 years of age, was admitted to the St. George's Hospital complaining of weakness, vomiting, and abdominal pains. He had suffered from pain in the epigastrium, immediately after taking food, for the past two years. The patient had two attacks of vomiting, one in July and August, 1900, and the other in November. The following report was made while the patient was in the Hospital: He complains of great weakness, he has lost weight, and suffers from constipation. The heart and lungs appear normal and nothing abnormal can be palpated in the abdomen. The blood revealed a slight leukocytosis; the urine varied in specific gravity from 1010 to 1030, and at times contained a trace of albumen, and indican in varying quantities. The vomiting material was bile stain and did not contain free acid. After persistent and copious vomiting the amount of urine decreased. On December 6th the patient vomited 11¼ pints in 15 hours. The diagnosis of stricture of the duodenum below the biliary papilla suggested itself. During the course of the illness the patient developed pyemia. The probable source of the infection was a transfusion wound. Death occurred from exhaustion on February 6, 1901. The post-mortem examination revealed a **tight-stricture of the third part of the duodenum**, due to a new growth which almost completely encircled the lumen of the bowel. Microscopically this tumor proved to be a columnar-celled carcinoma. The author believes that gastro-enterostomy would no doubt have relieved the patient temporarily, but the diagnosis was never sufficiently clear to justify laparotomy. The article is concluded with some general remarks on malignant disease of the duodenum. Mention is made of the frequency of carcinoma in this part of the intestine. The most frequent situation of primary cancer of the duodenum is in the second part, less frequently in the first part and the most uncommon position is the third part. [F. J. K.]

2.—Hughes calls attention to a morbid rhythmic activity of the brain which he has termed "**autopsychorhythmia**," or repetition psycho-neurosis. He gives a brief account of a number of such cases and maintains that this form of mental derangement is a forerunner of grave insanity. However slight and remote the symptoms may be, thorough investigation and prompt endeavor is imperative. [F. J. K.]

3.—Lamb writes upon the **correspondence between cholera and the prevalence of comma-bacteria in well water of Gujerat during the famine of 1900**. The results of his researches show that none of the comma-shaped bacteria isolated from Gujerat waters could be termed true cholera vibrio. There was, however, a marked resemblance morphologically, biologically, and tinctorially with the true cholera-producing microbe. So marked was this similarity that the author believes that the bacteria found belonged to the tribe of curved bacteria, which includes the true cholera-producing microbes. In many of the localities where these comma-bacteria were found, cases of true cholera were present, which shows an enhanced significance between the incidence of cholera in a locality and the presence of curved comma-shaped micro-organisms. [F. J. K.]

4.—A. C. Roper discusses the **diagnosis of the various abdominal conditions which may give rise to perforative peritonitis**, and the **best time to operate** in such cases. In perforation of gastric ulcer the four principle signs are rigidity, tenderness, the presence of fluid in the flanks, and free gas in the peritoneum, to which of course are added pain and the signs of collapse. These symptoms are very apt to be followed by amelioration which is oftentimes misleading. It is during this period of improvement, when rigidity is being followed by distension, when tenderness is less, when there is no passage of flatus, that operation should be done. Roper thinks that it is better not to operate immediately during the shock which follows perforation of a gastric ulcer, but to relieve the pain and treat the shock, all of which can be done while preparation is being made for operation. In any form of perforative peritonitis opium

must be given at first to relieve the suffering, but a diagnosis should, if possible, be made before the drug is administered. [J. H. G.]

6.—Coates discusses the cause and treatment of **profuse epistaxis in people beyond middle age**. He gives a brief report of 5 cases and states that the sequence of events leading up to the epistaxis was similar in all cases, namely (1) High arterial tension; (2) sudden cardiac failure either due to loss of power of the cardiac muscle, or from the giving way of valve; (3) overdistension of the whole venous system; (4) leakage following from an over distended vein. The author states that a question which naturally presents itself is, Why should only some individuals, suffering from circulatory diseases develop epistaxis. The most plausible explanation for this is that the relatively weakest point in those individuals, complaining of epistaxis, is probably in the venous sinuses of the nose. From the standpoint of treatment, (of these cases of epistaxis), the most satisfactory measures will be those which tend to relieve the passive venous distension by keeping down the high blood pressure and by strengthening the weakened heart muscle. In most cases plugging of the nostrils is unnecessary, as the hemorrhage can be controlled without resorting to this procedure, which is always uncomfortable to the patient and may even prove dangerous. The drugs which prove to be quite effective are nitro glycerine, amyl-nitrite, strychnia, and strophanthus. [F. J. K.]

5.—Stone reports a case of **cataplexy alternating with violent mental excitement**, occurring in a married woman 27 years of age. The condition had existed for some time before the author observed the case, which was on November 15, 1900. The attacks seemed to occur at or about the menstrual period. During one of the menstrual periods she passed a membranous cast of the uterine cavity and said that this had occurred some months previously. The patient also complained of dysmenorrhea and menorrhagia. Recovery seemed to follow dilatation of the cervix and curettement of the uterus. [F. J. K.]

7.—Charles A. Morton reports a case of **diffuse peritonitis**, the result of a **perforated appendix**, which recovered after operation and thorough drainage. The case is interesting because it shows the danger of delaying operation in patients who have suffered from previous attacks of appendicitis. In this instance the patient had three previous attacks. On the first day it was thought that the patient might recover from his attack and no operation was advised. 48 hours after the commencement of the attack there was distension, more general tenderness and abdominal breathing had disappeared. All of the lower portion of the peritoneal cavity was found to be involved and a large quantity of pus was evacuated from the pelvis. [J. H. G.]

8.—Bartlett gives a detailed report of a case of **phthisis** and discusses the value of **open air treatment at home**. The patient, age 38, the wife of a baker, residing in the country two miles from a small town, complained of cough and expectoration, shortness of breath, severe night sweats, weakness, anorexia, and had lost weight. Fever was present; well marked physical signs of consolidation in the upper lobe of the left lung and cavity formation were elicited. Tubercle bacilli were found in the sputum. The author advised open air treatment. Improvement gradually followed; the patient gained weight, fever subsided and tubercle bacilli disappeared from the sputum. [F. J. K.]

MEDICAL RECORD.

May 1st, 1901.

1. The Operation for Radical Cure of Inguinal Hernia. CAMPBELL FORD.
2. Varicella in Adults. ALVAH H. DOTY.
3. A Plea for the Conservation of Breast Milk in Whole or in Part. THOMAS S. SOUTHWORTH.
4. On Bandages for Nephroptosis. GEORGE M. EDEBOHLS.
5. Version, Indication, Technique, Limitation. S. MARY.
6. Axis-Traction Forceps. EGBERT H. GRANDIN.
7. Caesarean Section. EDWIN B. CRAGIN.

1.—Campbell Ford has had the opportunity of being present at operations performed for the radical cure of inguinal hernia by Bassini, Lucas-Championniere, De Garmy, Coley and Broca which he describes. He approves of De Garmy's method of using kangaroo tendon as suture material or, in lieu of it, silk, and also endorses this surgeon

method of suturing the external oblique and the pillars of the ring by taking a wide stitch. He advocates the use of a **Reverdin needle** and the square-knot stitch for the deepest layer and also uses the lap insertion. [T. L. C.]

2.—**Alvah H. Doty** states that the prevalent belief that **chickenpox does not affect adults is erroneous**. He believes that it occurs in typical form in adults and discusses the character of the eruption, the manner in which it appears and its distribution or location. Even in mild cases of smallpox the hands and feet are to some extent involved, but in chickenpox, even with a profuse eruption this is uncommon. The back presents the best surface to study the eruption of varicella. [T. L. C.]

3.—**T. S. Southworth** makes a plea for the **conservation of breast milk in whole, or in part**. The cases in which the breast milk is thought to be at fault may be of two varieties. In the first are those children who appear to be gaining satisfactorily in weight but are suffering from colic, vomiting, crying or disturbed stools. It is necessary to determine whether the child is still gaining weight, and if this is the case the other ills may usually be remedied. The diet of the mother must be investigated and regular period of nursing insisted upon. In the second class are included those children who do not appear to thrive on breast milk, and who in addition to their small weight may present symptoms of irritability and indigestion. In these cases accurate weighing of the child every second day is important. It is necessary to examine the mother's breasts, correct her diet, insist upon regular periods of nursing and these simple methods will frequently be followed by improvement in the child's condition. Should they fail **supplementary feeding** may be resorted to. [T. L. C.]

4.—**G. M. Edebohls** describes the **various bandages for nephroptosis**. The bandages for this condition may be divided into two general classes. Simple bandages and apparatus embodying the feature of a special kidney pad. The simple bandages act by supporting the entire contents of the abdomen and more or less immobilizing the moveable kidney on the intestinal mass. All of the relief derived from bandages encircling and sustaining the lower two-thirds of the abdomen, or from a long and low reaching corset have the same object. The relief obtained will depend upon the presence and the degree of any associated **enteroptosis**. The greater the degree of this condition the better are the prospects of relief from bandage or corset. When movable kidney exists without general enteroptosis no form of apparatus will prove satisfactory. The writer believes that all appliances with special kidney pads or trusses are useless and injurious, and that the operation of **nephropexy** is indicated when relief of symptoms cannot be obtained from a simple bandage or corset. [T. L. C.]

5.—The indications for **version**, according to Marx, are: 1. Malpositions and malpresentations; 2. contracted pelvis, either relatively or absolutely so; 3. Prolapsus funis or allied conditions; 4. For all other unclassified conditions, such as placenta previa; 5. Except under very rare conditions in all cases in which the head remains above the brim; the exception being in those cases in which there is present a uterine rupture or a very much thinned-out lower uterine zone showing plainly the contraction-ring of Bandl. Finally, it may be stated in general terms that version is indicated in all cases in which the life of the mother is threatened, as by uremic convulsion or an embolus of the lung. Under these conditions a dilatable or one that is fully dilated must be presupposed. When the latter conditions do not obtain the version must be immediately anticipated by a rapid manual dilatation or a deep **Duehrssen's** incision of the os. The lowest limit for a deliberate elective version would be in the case of a pelvis whose true conjugate is at or above $3\frac{3}{4}$ inches in the presence of an average size or small child. The extreme lowest limit in the **Walcher** position is 3 inches. Marx believes that the operation of **symphysiotomy** finds no indication in pelvic contraction. [W. A. N. D.]

6.—**Gardin** remarks that **forceps applications** is conven-

iently divided into high, median and low. For the purpose of low application any type of forceps should answer, and similarly in the case of median application in instances in which deficiency in the expelling force is at the bottom of the retardation in labor. High application in his hands is limited to instances in which the membranes have ruptured and the presenting part has just engaged. The **axis-traction instrument** should fulfil the following indications: 1. Traction in the correct axis; 2. traction with expenditure of the least effort on the part of the operator; 3. Traction with the least compression of the fetal head; 4. Traction with the least interference with normal mechanism (e. g., rotation); 5. Traction with the least consequent damage to the maternal parts. The rules governing the application of the axis-traction forceps are similar to those associated with other types. In high application the blades are applied to the sides of the pelvis; in median application to the sides of the fetal head. [W. A. N. D.]

7.—**Cragin** records a series of 9 cases of **Caesarean section** which illustrate the various indications for the operation. He remarks that a deliberate craniotomy, or endryotomy upon a living child, with the mother in good condition, is justifiable only in conditions of emergency and extreme infrequency. He admits that in private practice the obstetric surgeon must be governed largely by the wishes of the family and friends of the patient who may prefer a craniotomy to a Caesarean section. There are two periods when the question of delivery by a cutting operation presents itself for acceptance or rejection: 1. Early in pregnancy when a prognosis of a difficult or obstructed labor is made; 2. in labor, difficult or obstructed. At the time of labor several questions present themselves: 1. Can the woman be delivered of a living child by forceps or version? 2. Is the woman in good condition? 3. Is the child in good condition? If the first question is answered in the affirmative the cutting operation should not be considered. If the woman is in a poor condition Caesarean section should yield to a craniotomy be the child living or dead. If the child is in poor condition all cutting operations upon the mother should yield to craniotomy, unless the parturient canal is so obstructed that delivery by craniotomy would expose the woman to greater danger than Caesarean section. The latter operation, viewed from the standpoint of mortality, ease and rapidity of convalescence and ease of the surgeon, deserves the preference over symphysiotomy. [W. A. N. D.]

NEW YORK MEDICAL JOURNAL.

May 4th, 1901. (Vol. LXXIII, No. 18.)

1. Abdominal Pain in Typhoid Fever. **THOMAS McCRAE**.
2. Spinal Anesthesia by Cataphoresis. **J. J. LEONARD CORNING**.
3. The Pathology and Bacteriology of the Uretero-intestinal Anastomosis. **F. ROBERT ZEIT**.
4. The use of the Suprarenal Capsule in Diseases of the Heart. **SAMUEL FLOERSHEIM**.
5. The Law and the Inebriate: with Remarks on the Treatment of Inebriety. **JOSEPH COLLINS**.

1.—**McCrae** sums up the cases in which there was **abdominal pain in typhoid fever** as follows: (1) About two-fifths of patients were without pain, one-fifth had tenderness, two-fifths had pain sometime during the disease, and one-third had pain through the entire course; (2) Pain due to some condition other than the specific bowel lesions was present in about 14 per cent. of all cases and in about two-fifths of the patients having pain during the course; (3) Pain occurred with hemorrhage or perforation in about 5% of all cases and in about 15% of the cases in which there was pain during the course; (4) Pain was most constantly present with perforation, when it was sudden in onset, severe in character and paroxysmal in occurrence. The pain of perforation was most closely simulated by that occurring in some cases of hemorrhage, that from phlebitis, and that of unknown origin; (5) In about two-fifths of all cases with pain during the course no cause could be found. Should this occur with other abdominal symptoms the condition may much resemble perforation. [T. M. T.]

2.—Dr. Corning proposes to produce **spinal anesthesia** by **cataphoresis** in the following manner: The apparatus consists of a tube four inches long, terminating at one end in a small metal bulb, pierced to give passage to a tube of smaller calibre, upon passing the latter down through the larger tube. At the other (upper) end of the larger tube is a binding-post for securing the conducting cord (positive pole) of a galvanic battery. The smaller tube, which projects an inch and a quarter beyond the upper end of the larger tube, is provided with the socket requisite to attach it to a hypodermic syringe (glass). A diminutive metal collar, sliding along the smaller tube between the socket and the upper end of the larger tube, may be kept in place at any point by the aid of a small set-screw. By this device it is possible to regulate accurately the distance to which the small tube shall be thrust beyond the bulbous end of the larger tube (about half a centimetre). The lower end of the smaller tube has no bevel whatever, and is slightly rounded at the edges. The larger (outer) tube is insulated throughout its entire length, save at the bulb, which is bare. He proposed to introduce the larger (insulated) tube between the spinous processes of the third and fourth lumbar vertebra till the metal bulb was stopped by the ligamentum subflavum, then to thrust forward the inner tube sufficiently to pierce the ligament, yet leave the dura and arachnoid unscathed, a thing very easily done, as these membranes, bolstered only by the yielding cerebrospinal fluid, would inevitably give before the rounded end of the small tube, which could at most indent, but never pierce them. Once having pierced the ligamentum subflavum, attach the syringe to the small tube, and inject the anesthetic upon the dura. This done, unscrew the syringe, withdraw the smaller tube, secure the positive conducting cord of a galvanic battery to the binding-post of the larger tube—the negative sponge of the battery being already over the abdomen—cause the current to pass. The cataphoretic action thus resulting would, he hoped, materially aid the passage of the anesthetic through the membranes. [T. M. T.]

4.—Floersheim, in his article on the use of the **suprarenal capsule in diseases of the heart**, advises the use of the dried and powdered gland, which can be kept indefinitely. He places it in a gelatine capsule, as the tablet form is useless. The dose is three grains, but larger doses, one drachm or more, are not injurious. In administering, the capsule must be thoroughly chewed, dissolved in the mouth and swallowed without water. For children he advises an emulsion by the mouth, three grains of the powder mixed in a little water in a teaspoon. The action of the extract became apparent in less than five minutes. The effect continues from five minutes to three hours or longer. It is not poisonous and has no accumulation effect like digitalis, and does not act upon the nervous system. [T. M. T.]

MEDICAL NEWS.

May 4, 1901. (Vol. LXXVIII, No. 18.)

1. Medical Department of the University of Pennsylvania. CHARLES W. DULLES.
2. A Report of Twenty-four Operations Performed during Spinal Analgesia. WILLIAM SEAMAN BAINBRIDGE.
3. Some Sources of Error in Laboratory Clinical Diagnosis. THEODORE C. JANEWAY.

2.—Bainbridge, in his article on **spinal analgesia**, prefers cocaine to eucain for the following reasons: (1) The latter is less potent, more evanescent, the areas of analgesia are frequently "patchy." Cocaine produces no more unpleasant after effects and it decidedly more reliable: (2) Analgesia to the level of the diaphragm can be depended upon in all cases in which it is introduced by lumbar puncture. In some instances the analgesia is sufficient for operations on the upper extremities; (3) Complete analgesia, including eyes, nose and throat has occurred; (4) Preparation of the patient as for a general anesthetic diminishes all the unpleasant effects and often prevents them; (5) By moderate doses of bromide before injection the initial vomiting is frequently avoided and liability to headache lessened; (6) Hysterical symptoms occur, but as a rule, a few moments after the injection the patient becomes quiet; (7) Initial nausea and vomiting often occur soon after injection, but only last for a moment and usually do not happen during operation; (8) Analgesia lasts from thirty minutes to four hours; (9) Depression after puncture is inconsiderable. Ethyl

chloride largely prevents pain when the needle is introduced; (10) Using nitroglycerine by hypodermic injection, or one of the coal-tar products with caffeine, controls the headache; (11) There may be motor paralysis or vertigo, but both are temporary; (12) Spinal puncture has no effect on normal or diseased kidneys; (13) Usually the tactile power, muscular sense, and the ability to detect heat and cold are retained; (14) The patient generally sleeps the first night; (15) Often slight temperature within eight or ten hours after operation. The circulation and respiration are not seriously embarrassed. [T. M. T.]

3.—Janeway considers that the **sources of possible error** in the application of **laboratory methods to diagnosis** are those due to the methods themselves or faulty technique in their use and those due to inaccurate reasoning from accurate results. He also gives a few of the commoner sources of error. (1) In testing for albumin, one of the most frequent is not filtering the urine, as it is absolutely impossible to make a delicate test without it; also in Heller's test where there is a small quantity of albumin, the test should not be discarded until at least fifteen minutes have elapsed. In the heat and acid test the upper part of the urine should be boiled and acid added so that a comparison can be made with the clear urine. Tests made by dropping the solution into the urine should always be judged by the side of a tube of filtered urine. The acetic-acid and ferrocyanide test needs a special check, not with clear urine but with urine to which acetic acid has been added. In diagnosis of diseases of the urinary apparatus the detection of serum albumin and globulin, and possibly abnormally large amounts of nucleio-albumin is important, and the most reliable tests for these substances are Heller's, the acetic acid and potassium ferrocyanide tests: (2) In testing for sugar, he does not consider the Fehling's test as reliable as the polariscope, fermentation and phenyl-hydrazin reaction, and only uses it for excluding the presence of the sugar, as various drugs, rhubarb, salicylates, camphor, etc., will give some sort of reduction. Another common error is in connection with specific gravity, concluding that urine does not contain sugar when it is 10.20 or below. Still another error is overlooking the significance of urine of constant low specific gravity. This he states, strongly points to the existence of contracting kidney. He advises urine to be examined to be procured at three different times—morning, late afternoon and on retiring, instead of taking the whole twenty-four hours' urine. (3) In examination for urea the greatest difficulty is the inaccuracy due to decomposition of the urine, especially in summer, causing considerable loss. (4) In the examination of the sputum the physician always looks for tubercle bacilli, when in the unstained expectoration Charcot-Leyden's crystals and Curschmann's spirals can be found. (5) In the blood examination not enough attention is paid to the marked leucocytosis present in continued fevers, which points to the existence of sepsis, and in the diagnosis of appendicitis their increase should give more weight to the diagnosis. [T. M. T.]

BOSTON MEDICAL AND SURGICAL JOURNAL.

1. Contusions of the Abdomen. CHARLES L. SCUDDER.
2. Observations on the Use of Antistreptococcus Serum in the Treatment of Puerperal Sepsis with a Report of Five Cases. FRANK A. HIGGINS.
3. A Case of Caesarean Section, Complicated by Uterine Fibroid. EMMA S. CALL.

1.—Scudder discusses the treatment of **contusions of the abdomen**, and especially a group of acute abdominal emergencies due to traumatism. Injuries to the **ureter** in addition to the general symptoms of shock, which may subside within a few hours, are characterized by little blood appearing in the urine and perhaps only an occasional clot. If no lesion of an abdominal organ accompanies rupture of the ureter, no very great symptoms will be manifested. Transient hematuria should not be overlooked, especially with persistent pain in the side. Treatment is briefly described. Rupture of the urinary bladder, of the liver, contusions of the kidney, injury to the stomach, rupture of the intestines, lacerations of the spleen, injuries to the pancreas, shock, hemorrhage and peritonitis are described. He calls attention to the shock which is present in almost every abdominal contusion of consequence. Shock varies

in individuals affected by the same lesion according to the temperament and nationality of the patient. An absence of shock does not signify the absence of a serious lesion. The conditions of the pulse, and temperature are discussed as diagnostic factors. When the pain depends upon the hemorrhage other signs of hemorrhage will accompany the pain. Tenderness, vomiting, distension and rigidity of the abdominal muscles are carefully considered. [M. R. D.]

2.—Higgins reports his observations on the use of antistreptococcus serum in the treatment of puerperal sepsis with a report of five cases. His observations are confined to the use of the serum in five cases occurring during the past year. He thinks that we cannot fail to be disappointed in the result of the serum treatment and are obliged to conclude that as a curative agent its power is limited. The author believes that the serum has a marked depressing effect upon the patient and is not to be indiscriminately administered to a very sick patient repeatedly and in large quantities, as is sometimes done in following the directions that come with the serum. He further believes that the serum treatment has no position in the routine treatment of puerperal sepsis that it should only be employed in such desperate cases after one has failed to obtain improvement by other efficient remedies, and that if then no improvement is manifested within two, or at the most three days after 40-60 ccm. have been used, it should be discontinued. [M. R. D.]

3.—E. S. Call reports a case of Caesarean section in a case of face presentation complicated by uterine fibroid. The patient, aged 20, in her second labor was an apparently healthy woman, whose first labor 15 months before had been apparently normal and not unusually protracted. Upon examination the os was found dilated about the size of a silver dollar, the membranes still unruptured but relaxed, and the face of the child presenting in the right mento-posterior position, but still above the brim of the pelvis. Ordinary manipulations having failed and the life of the child being in jeopardy. Caesarean section was performed by Dr. Alexander. After the incision an interstitial fibroid was discovered. The results were entirely satisfactory. [M. R. D.]

JOURNAL OF AMERICAN MEDICAL ASSOCIATION.

May 11th, 1901.

1. The Gyromele in the Diagnosis of Stomach and Intestinal Diseases. FENTON B. TURCK.
2. A New Operative Method to Expose the Seminal Vesicles and Prostate Gland for Purposes of Extirpation and Drainage. A Preliminary Report. EUGENE FULLER.
3. Myasthenia Gravis Pseudoparalytica (Asthenic Bulbar Paralysis). J. T. BUIST and E. G. WOOD.
4. Limitations of the Laryngologist in the General Treatment of Nose and Throat Diseases. H. W. LOEB.
5. Absolute Increase of Measurement from the Anterior Superior Spine to the Malleolus as a Sign of Hysterical Hip Disease. JAMES JACKSON PUTNAM.
6. A Case of Transient Motor Asphasia, Complete Anomia, Nearly Complete Agraphia and Word-blindness Occurring in a Left-Handed Man; with Special Reference to the Existence of a Naming Center. CHARLES S. POTTS.
7. The Pharmacology of the Nitro-Sugars. C. R. MARSHALL.
8. The Classical Cesarean versus Porro Cesarean. GEORGE M. BOYD.
9. Ocean Climates; Their Effects and the Cases they Benefit. JOHN A. ROBINSON.
10. Adhesive Rubber Dam for the Prevention of Possible Infection at the Site of Operation. J. B. MURPHY.
11. The Present Status of Spinal Surgery. SAMUEL LLOYD.

1.—Turck mentions the usefulness of the gyromele in the diagnosis of stomach and intestinal diseases. The gyromele, or revolving sound, is made of a flexible steel cable, the end of a more flexible steel spiral, and the tip of the spiral steel is provided with a metallic pellet covered by a sponge, cotton, or lamb's wool. A revolving apparatus is fastened to the sound. The scope of usefulness of the gyromele is not restricted to the investigations of the stomach alone; the nose and throat, the esophagus, the

pylorus and the small intestine, the colon, the bladder, the uterus, the thoracic cavity, and false cavities of various kinds have all been successfully explored. [F. J. K.]

2.—Eugene Fuller describes an original operation for gaining access to the seminal vesicles and prostate gland. The patient is placed upon the table with his face and abdomen down and his thighs flexed upon the abdomen astride of the table. The portion of the table which supports the pelvis is then elevated as in the Trendelenburg position. The incision extends on either side of the anus along the inner side of the tuber ischi, and is connected by a transverse cut across the perineum about $\frac{3}{4}$ -inch anterior to the anus. The rectum is then carefully lifted up and separated from the urethra and bladder by careful dissection. The finger in the rectum enables the operator to avoid wounding this organ. Fuller has used this method on five occasions for operations of various kinds upon the seminal vesicles, and has found it most satisfactory. His article is illustrated by three cuts which show the position on the table and the line of incision. [J. H. G.]

3.—Buist and Wood, in an article on myasthenia gravis pseudoparalytica, state that little is known of the etiology and pathology of this disease. It is characterized by muscular weakness, rapidly coming on exhaustion, and the presence of the myasthenic reaction. The bulbar muscles are not only affected, but also those of the eye and extremities. Exacerbation and remissions, varying in intensity from day to day, are of common occurrence. The intellectual and sensual powers are not impaired, and the reflexes are undisturbed. Muscular atrophy, fibrillar twitching, sensory disturbances, reaction of degeneration, and bladder and rectal troubles are not features of this disease. The cranial nerve muscles are, as a rule, the first involved; ptosis or diplopia being early manifestations. In some cases permanent paralysis develops, which may affect any of the voluntary muscles. It is a remarkable fact that with such pronounced motor defects often terminating fatally, there is complete absence of so many of the signs of organic disease of the nervous and muscular systems. Out of 63 cases there were 23 fatal ones. There are no known remedies which seem to influence the course of this disease. The article is concluded with a report of a case. [F. J. K.]

4.—Loeb concludes that the limitations of the laryngologist in the general treatment of the nose and throat are the following: (1) Nose and throat conditions of an acute character influenced by measures which have an important local effect; (2) nose and throat diseases of a rheumatic character which, under appropriate treatment, are relieved early; (3) syphilitic nose and throat diseases, the general treatment of which being best observed by watching the effect upon the local lesion. Even under the conditions named the assistance of one who is less directed to localism may be advantageous to the patient. [F. J. K.]

5.—Putnam gives an account of a case of hysteria in which there was an absolute increase of measurement from the anterior superior spine to the internal malleolus. After a prolonged and careful study the diagnosis of hysterical hip disease was made. Marked thickening in the region of the affected trochanter was noticed after the patient had been under observation for fifteen months. This swelling was believed to be due to hysteria edema. Upon pressure tenderness was present. The patient improved greatly under treatment, but did not recover entirely. The author mentions that the last account received of her was that she was still lame. [F. J. K.]

6.—Potts gives a report of a case of transient motor aphasia, complete anomia, nearly complete agraphia, and word blindness, occurring in a left-handed man, aged 42 years, a coal miner by occupation. In summing up the symptoms the author states that there was loss of the power of naming objects seen, felt or heard, smelled or tasted. The patient could not repeat the name of an object. There was almost complete word blindness, however, the power of recognizing and reading the numerals was preserved. There was inability to write spontaneously, except his name and address, and the power of writing from dictation was very imperfect, and to read from a copy was impossible. The muscles of the tongue and lower part of the face on the left side were paralyzed. From the suddenness of onset the condition was probably due to an embolus or hemorrhage. [F. J. K.]

8.—Boyd remarks that the life of the infant alone under certain conditions justifies the Cesarean section. The classical Cesarean section has as low a mortality as an

easy ovariectomy. The life of the child should then be as good a reason for performing a simple abdominal section as are the vague symptoms for which operations are daily done. The classical Cesarean section is less mutilating than the Porro Cesarean section, and with the patient in good condition, is therefore the operation of choice. The Porro Cesarean section has about the same mortality as has hysterectomy for fibroids. It should be performed when the patient demands it or when infection or a neoplasm of the uterus makes it necessary. It is the duty of the practitioner in attendance on a multipara with the history of one or more dead children to be prepared to perform the Cesarean section. [W. A. N. D.]

9.—Robison discusses the **beneficial effects of a sea voyage**. Ocean climates are more equable and the desires of the traveler to spend most of the time in the open air, enforces rest, revives the exhausted body, and creates an appetite. The sea air increases metabolism, weight, inclination to sleep, and it also acts as a sedative on the nervous system. [F. J. K.]

10.—J. B. Murphy recommends the use of an adhesive rubber dam over the field of operation in order to prevent possible infection from the patient's skin. The dam is prepared by Johnson & Johnson, and is made to adhere closely to the skin and is not affected by any of the wound fluids or by antiseptic solutions. As the dam adheres closely to the skin the incision is made through it as if it were a layer of skin itself. It is retained in position until the stitches are introduced, and then it is removed. A small amount of ether on the skin of the patient increases the adhesive quality. The author has found it useful where wound fluids are continually flowing over the adjacent skin, as it here prevents irritation of the skin. [J. H. G.]

11.—Samuel Lloyd concludes his discussion of the **present status of spinal surgery** with statistical proof of his assertion that it is better not to operate immediately after the receipt of injuries to the spine, and he urges that when the operation is undertaken that it should be thorough, all possible pressure from the cord being removed. Shock is probably the greatest danger of the operation; hemorrhage he has not found difficult to control where packing has been used for a short time, the use of hemostats, however, only delays the operation. The loss of cerebro-spinal fluid possesses no particular danger. In one of his own cases a fistula discharging cerebro-spinal fluid continued for 12 weeks without inconvenience to the patient. Four cases operated upon for fracture dislocation of the spine are added to the author's former report of his personal experience. [J. H. G.]

AMERICAN MEDICINE.

May 4th, 1901.

1. An Analysis of my Vaginal Ablations in 181 Cases of Pelvic Inflammation and Utrine Fibroid Degeneration. W. R. PRYOR.
2. Inguinal Hernia. MERRILL RICKETTS.
3. Vaginal False Membrane due to Bacterium Coli. J. N. HALL.
4. A New Series of Anaerobic Bacteria. LOUIS LEROY.
5. Conclusions from Personal Observations of Compound Fractures. DOUGLAS C. MORIARTA.
6. The Food Value of Alcohol, and Professor Atwater's Experiments and Teaching. JOHN MADDEN.
7. Some Remarks on the Cumulative Action of Digitalis, with an Illustrative Case. EDWIN ZUGSMITH.
8. Prolonged Intubation. EDWIN ROSENTHAL.

1.—Pryor remarks that the first surgeons who brought the **vaginal radical operation** to this country seemed to have abandoned it almost entirely. His own experience with the application of the vaginal method of operating, not only in those cases which require the radical procedure, but also in those in which conservatism may be applied has been such as to convince him that the greater proportion of operations now performed through the abdomen could more easily and with better results be made through the vagina. In the last six years he has been enabled to cure by the vaginal operation 83% of all those who have applied to him and without mortality. As to the indications for the radical operation he does not consider the presence of pus

an invariable indication for the removal of a pus-sac. Pus-foci of gonorrheal origin in young women may very safely be broadly incised and allowed to heal up. This process prevents the disagreeable effects of a periclitate menopause. In those who have suffered from repeated attacks the radical operation is preferable. Ectopic gestation of one side associated with inflamed adnexa of the other indicates ablation. Hydrosalpinx of both sides associated with many adhesions may be treated conservatively or radically according to the surgeon's judgment. Cases of genital sclerosis indicate a radical treatment. Pryor protests against the removal of one pyosalpinx and leaving the other tube although it be apparently normal. He opposes myomectomy except in rare instances. He remarks that the firmness of structure and character of the vaginal canal have much to do with the facility of operating through the vagina in fibroid cases. The vaginal method is particularly applicable in intraligamentous and retroperitoneal fibroids and in fibroids associated with pus. After the operation the average time in bed is about three weeks and most patients return home within four weeks. He has found no shortening of the vagina after vaginal ablation nor has he heard any complaint of dyspareunia. [W. A. N. D.]

2.—B. M. Ricketts gives an anatomical description of **Inguinal Hernia** and details differences of opinions existing among surgeons on certain points. From a consideration of the anatomy of the structures involved in inguinal hernias it will be seen that they lack vascularity and nerve supply. The ventral hernia following laparotomy is ascribed to the division of the motor nerves. The abdominal muscles lose their innervation and undergo paralysis and atrophy; hence atrophic and weakened abdominal walls are easily protruded in response to intra-abdominal pressure. In at least 10% of cases operated upon the adhesions resulting from the closure of the inguinal ring are inefficient. This is true with all kinds of sutures. The ideal material for this purpose is one of sufficient life to permit a deposit of new tissues upon the peritoneum externally. The author believes after discussing the merits and demerits of the various sutures commonly employed that the use of a **wire mattress** meets all objections that can be urged against the other means of uniting the severed tissues. He denies the influence of infection in causing recurrence of hernia and attributes such an event to imperfect methods. The views of Coley, Fenger, Marcy, Phelps and Warren are given, as to the cause of failure and the percentage of recurrences after operations for hernia. [T. L. C.]

3.—Hall records a case of **vaginal false membrane** due to the *Bacterium coli* in a young girl of 14 years. This was removed after the application of the 1:5000 bichloride solution, after which the symptoms disappeared. He remarks that the diseases caused by this bacillus are rather within the body than on the external surfaces. Thus it may cause cystitis, nephritis, pyelonephritis, perinephritis, peritonitis, endocarditis, icterus, disease of the gall-bladder, meningitis, lymphangitis, urethritis, abscess, sepsis, pyemia and septicemia. It is possible, he concludes, that other membranes ordinarily considered diphtheric may be found to be due to the *Bacterium coli*. [W. A. N. D.]

4.—Louis Leroy mentions the fact that the importance of **Anerobic Bacteria** has been overlooked in the past. Following a systematic series of researches he has been able to isolate 14 species of strictly anerobic organisms. These are the principal agents of a whole series of affections of a gangrenous or putrid nature. They have been isolated in otitis, pulmonary gangrene, appendicitis, puerperal infection and a host of other conditions. These bacteria have the property of causing **necrosis in living tissue** and to produce a process of disintegration in them analogous to putrefaction. They not only act locally but by the toxins which they secrete provoke general poisoning. The writer hopes in the near future to have a **sero-therapeutic treatment** which will be rational and efficacious. [T. L. C.]

5.—D. C. Moriarta presents his conclusions from personal observation of **compound fractures** with clinical notes of 5 cases. He urges that in compound fractures, when the pathological condition is not positively determined, that the puncture or laceration be enlarged and the bone fully exposed, approximated and held in position. [T. L. C.]

7.—Edwin Zugsmith reports a case illustrating the **cumulative action of digitalis** in a female child of 23 months. It seemed reasonable to the author that since fever is an admitted hinderance to the action of the digitalis if the child's temperature could be raised by harmless means, the digitalis which had been administered might be rendered inactive for a long enough time to prevent its cumulative action. Hot air was employed in the effort to raise the child's temperature but did not subserve its purpose, the thermometer registering but 99 degrees in the rectum immediately after the hot air bath. The child, however, recovered. [T. L. C.]

8.—E. Rosenthal illustrates a short article on **prolonged intubation** with the report of a case. He states that it should be a rule of practice to remove the tube within five days after the operation unless it be removed by expectoration before, and then be no longer required. All cases requiring a tube for a longer period than five days should receive large doses of strychnia and constant re-intubation and extubation daily or every second day and progressively smaller tubes should be used until the case no longer requires it. [T. L. C.]

BERLINER KLINISCHE WOCHENSCHRIFT.

February 18, 1901.

1. The Removal of the Waste Water of Cities. GAERTNER.
2. Concerning a new Method for Differentiating between Human and Animal Blood for Medico-Legal Purposes. A. WASSERMANN and A. SCHUETZE.
3. The Feeding of Infants with Whole Milk. E. SCHLESINGER.
4. Abortion with Poisons. G. SCHWARZWAELIER.

2.—The authors describe the results which they have obtained by the method recently reported by Uhlenhuth. They injected human blood serum into rabbits, and found that the **blood serum of the rabbits afterward had a specific action upon a solution of human blood** but upon no other blood excepting that of apes. The reaction occurred within twenty minutes, or even earlier. It acted even with blood that had been dried for three months, and under these circumstances also was entirely specific. They decide that if a reaction occurs within a half hour to one hour that the suspicious blood may be considered to be human blood if it had been tested by the serum of a rabbit that had been treated with human blood. A test should always be carried out with controls, using in the latter other varieties of blood. If the reaction occurs, and there is no possibility that the blood could be that of a monkey, one may decide positively that it is human blood. [D. L. E.]

3.—Schlesinger first states that we do not know that the mere dilution of cow's milk makes the milk any more digestible, indeed the result of mere dilution is to introduce a smaller quantity of actual nourishment with the same bulk of food, and if the child is given the proper quantity of food with a much diluted cow's milk, it means that the infant must take large amounts of water, and it is altogether probable that these large amounts of water are not wholly without damaging results. The child must use a great deal of energy in an abnormal way in absorbing and again excreting the mere water. Wassermann describes results which he has had from the use of whole milk after the children had been put upon diluted cow's milk, and presents tables to show the remarkable improvement which occurred after such a change in diet. The cheapness of cow's milk, and the readiness with which whole milk is used, makes cow's milk the most satisfactory of all foods that can be used, and he believes that the use of whole milk will come to occupy a much more important place than it now does. [D. L. E.]

4.—Schwarzwaeller directs attention to the fact that it is known that **criminal abortion is sometimes brought on by**

using lead. He himself reports 4 cases in which it was definitely determined that lead was taken for this purpose, and in which a diagnosis was made by discovering a blue line on the gums. He states that he knows 14 similar instances, some of which he has himself seen, the others having occurred in the practices of colleagues. As a rule the diagnosis in these cases was at first acute gastritis, renal colic, tubal inflammation, and similar conditions. In many cases the patients misrepresented matters absolutely, and there was not the least suggestion in their story of the actual cause of their condition. Lead can be obtained by any one, and its sale cannot well be forbidden; its use, therefore, may be easily carried out by any one, and it is wise in all suspicious instances to examine the gums, and to consider the possibility of lead poisoning, voluntarily undergone for this purpose.

JOURNAL DES PRATICIENS.

March 16, 1901. (15 me. Annee, No. II.)

1. Chylous Ascites. M. RENDU.
2. Wells, their Impurities and Disinfection. P. REILLE.
3. Lavage of the Stomach in Gastrorrhagia. G. LINOSSIER.
4. The Diagnosis and Treatment of Foreign Bodies in the Nasal Fossae. A. COURTADE.

1.—Rendu reports the case of a woman, 42 years old, who, a year ago, noticed edema of both feet and legs below the knees. There were no varicose veins. Ascites developed. Six months later the edema of the legs reached the hips, and spread into the lumbar region. Nausea occurred, without vomiting, but with diarrhea. She grew thinner, and passed but little urine. There was so much anasarca that fluctuation was hardly obtainable, though ascites was evident. Varicose lymphatic vessels appeared in the suprapubic region. The edema made the skin hard as in elephantiasis. There was bilateral pleural effusion. The absence of any albumin in the urine at any time eliminated nephritis. The history excluded cirrhosis of the liver. Nor were there any typical signs of peritonitis. Tapping the swollen abdomen revealed **chylous ascites**. The liquid looked like diluted milk. It contained irregular fat droplets, which, on being estimated quantitatively, showed from 6 to 8 grams of fat to the liter. Rendu considers this a true case of chylous ascites, probably due to compression or rupture of the thoracic duct by a cancerous or tuberculous growth. There were, however, no other signs of tuberculosis or cancer. The prognosis is grave. Exploratory laparotomy may cause some improvement. [M. O.]

2.—Reille discloses the impurities in surface well water in France, and suggests the addition of potassium permanganate as a means of disinfection. [M. O.]

3.—Linossier believed until recently that it was dangerous to introduce the **stomach tube in cases of hemothemsis**. But in the past two months, he has treated two cases which have disproved this. The first case, a woman aged 46, had been treated for hepatic colic. Upon examination, Linossier found symptoms of a gastric neoplasm, though no tumor was palpable. She had great pain and vomited blood constantly. As nothing did any good, Linossier washed out a great quantity of dark blood and food, with the stomach tube. The immediate result was excellent. He repeated it daily, and found no more blood the third day. She improved markedly. The other case, a woman 71 years old, had cancer of the pylorus. She also vomited blood, and had great pain. Her stomach was much dilated. Lavage relieved the condition at once, and was repeated. She improved also. Lavage seemed to Linossier the only way to put the stomach at absolute rest, beside tending to clot formation. [M. O.]

4.—The diagnosis of a foreign body in the nasal fossa depends upon its presence there, its nature, its size, and its shape. Sometimes these are known, oftener they are not. Before any attempts are made to extract the foreign body, it must be seen. Then its consistency can be tried, and some method followed for its extraction. Courtaud reports finding a cork (1 cm. by 1.5 cm.) in the nostril of a child of 7. It was incrustated with lime salts, of a consistency of stone. Any method of extraction applicable to the individual case should be employed, only care must first be taken to see the object to be extracted. [M. O.]

THE DOCTOR'S FEE.—A PLEA FOR HONORABLE DEALING.*

By JOHN B. ROBERTS, M. D.,

Of Philadelphia.

Ex-President of the Society and ex-President of the Medical Society of the State of Pennsylvania.

"Trust not to the omnipotency of gold, and sav not unto it thou art my confidence." * * * * *

"Persons lightly dipped, not grained in generous honesty, are but pale in goodness, and faint-hearted in integrity."

These reflections of the 17th century physician of Norwich seem a fitting introduction to this paper, prepared for the consideration of the 20th century physicians of Philadelphia.

Three hundred and fifty years have greatly changed, and for the better, the methods of treating disease, and have much increased the physician's knowledge of nature's processes; but the fundamental principles of medical conduct and of the doctor's relation to his patient are still unaltered and unalterable.

"That he be as free from crafte and deceyte in all his workyngs, as the East is from the Weast. * * * that he taketh no cure in the hande for lucre or gaynes sake only, but rather for an honest and competent rewarde with a Godly affection to doe his diligence." Such should be the true surgeon, said Thomas Gale, in 1563, in the first surgery written in the English tongue. His words may well be associated with William Bulleine's contemporaneous advice to the apothecary, "To remember his ende, and the iudgement of God; and thus I doe commend him to God, if he be not coueitous or craftie sekyng his owne lucre, before other mennes' health succour and comfort."

These quotations from our medical fathers sound a little old-fashioned, and look a trifle unfamiliar in their spelling. Would they not sound discordant if read in parallel columns with the following statements recently published in the official organ of the American medical profession. "It is openly charged that certain men are to-day giving commissions to physicians sending them cases." "A prominent physician not long ago read a paper before a medical society, in which he advocated a division of the fee" (between the family physician and the consultant surgeon).

It is not the wish of the author of this paper to pose as the Doctor Purissimus of some half jesting or half sneering friend; nor does he desire to offend his hearers, as did the clergyman, who was described by a prominent, but dissatisfied, member of his congregation as "too damned pious." It is but the truth, however, to state that some recent personal experiences and observations have been the exciting cause of the preparation of this communication to the Philadelphia County Medical Society.

To one who believes that the medical man belongs to a liberal profession and not to that portion of the body economic, whose sole object is the accumulation of money, certain tendencies now seen in

the ranks of medicine cause distress. The apparent drifting away from the ideals, which formerly held possession of the minds of physicians, forces the conclusion that a spirit of commercialism is replacing the spirit of professionalism.

No slur is meant to be cast on the merchant, tradesman or promoter, who endeavors to increase his capital or his earnings in honest business enterprises; no intention exists to deprive the doctor of his right to earn his living by collecting proper compensation for his professional services. The point insisted upon, however, is this: that the province of the doctor is to relieve the sick and suffering, and to subordinate to that first object of his calling, the obtaining of a financial reward for his labor. "Do your duty and then collect your money," is the physician's motto. "Be sure of your money before you deliver the goods," is the perfectly proper motto of the business man.

My critics say that it is difficult to determine what is a proper and just enterprise and thrift in one's professional work, and what is an improper commercial spirit. The decision should not be difficult for the honorable physician, who believes in the liberal spirit of his profession, and who is inspired by the ideals of Gale, Bulleine and Browne. In a recent discussion on the possible immoral tendency in art, a well-known teacher stated his opinion in some such words as these: "If the moral quality is so weak that you cannot taste it, and the sensuous so strong that you cannot miss it, then the work of art is dangerous, no matter how well it is done." A similar test is all that is needed when a conscientious physician wishes to know what is allowable in his relations with his patient. If the sincerity, humanity, generosity and truthfulness of an action cannot be readily seen; while its selfishness, cupidity and necessary secrecy are recognizable, he may be quite sure that it does not meet the requirements of professional standards.

Let me illustrate by a few examples:

A well-known optician recently called upon me and showed me a hollow gold ball to be used in Mules's operation on the eye. His argument was that the use of this gold ball, instead of the usually employed glass sphere, would make the patient willing to pay me a larger fee for my operation; since the operation would seem more important and expensive. In other words, my fee was not to be based on the skill and time required, but on the amount that the patient could be induced to give up without protest. I was to use a gold sphere, costing me three dollars, instead of a glass one costing thirty cents; not because it was better for the patient, which it wasn't, but because it would be a good bait by which to play on his ignorance for a double or triple fee. Such a trick may be "good business," but it doesn't appeal to a physician!

In my mail a few mornings ago I found the advertisement of a dealer in trusses, bandages, and other surgical appliances. Snugly wrapped in the circular was a neatly printed slip, telling me that 25% commission would be given to me on sales made to my patients.

Not many years since, a half page advertisement of a sanitarium appeared in a well-known medical journal, offering stock of the sanitarium company

*Read before the Philadelphia County Medical Society, April 10, 1901.

on very advantageous terms to doctors sending patients to that institution. It did not lessen the insult of this intimation to learn that the leading spirit of the Sanitarium Company was a Fellow of a learned medical organization of this State.

A certain mineral springs company has recently, it is said, offered its stock to physicians, so as to induce them to advocate the use of its water by their patients.

Who does not know that in this city some opticians give, and some oculists shamefully accept, commissions on sales made to patients? The public should realize that an oculist, who insists on his patients buying their glasses at one or two special stores, lays himself open to the suspicion of being bribed to do so by a commission from the dealer. The same suspicion attaches to the doctor, who unduly urges patients to buy medicines from one apothecary. It is true that spectacles and medicines should be accurately made and compounded; but there are usually too many reliable dealers, especially in large cities, to necessitate so restrictive a choice for the mere benefit of the patient.

Another scheme, to impose on the patient and extract from him what is practically two fees, consists in giving him a prescription for medicine under a special name, agreed upon by the doctor and the druggist with whom he is in collusion. The patient is then obliged to go to the apothecary mentioned by the doctor, even if it be several miles out of his way, under the impression forsooth that no other apothecary prepares the remedy so carefully!

This business enterprise is not unlike that practised by some hospitals, which, to obtain a large and interesting accident service, keep beer and whiskey ready for the men running the patrol wagon. Little wonder is it that the injured are at times driven many unnecessary squares, and that certain institutions can show an unusually long list of accident cases. Whether these institutions similarly profit by using their private wards and rooms as boarding houses for members of State Legislatures and their friends, who visit the centres of gayety for pleasure or business, need not be discussed in this paper.

Life insurance companies seem to me to have a code quite unlike that which the true medical profession believes to be honorable. A couple of years ago I received a letter from a well-known life insurance company of this city, saying that a Mr. So and So, who had applied for insurance, had once been under my professional care, and would I kindly give the company information as to my diagnosis of the obscure abdominal condition, to aid its medical examiners in arriving at a conclusion as to the character of the risk. This unwarranted inquiry, apparently made without the knowledge of the man, who had entrusted his health to a supposedly honorable physician, elicited no reply. Soon I received a personal letter from the Medical Director of the Company, who is an old and valued friend, making the same request. A firm refusal to disclose professional confidences, without the consent of the patient, closed the incident.

It is supposable that many insurance companies are doing this thing constantly. It is not likely that my experience was an isolated one. Are doctors to

be tempted by fees or claims of friendship to disclose professional confidences, because life insurance companies doubt the skill of their medical examiners?

Take another side of the fee question. A New England Insurance Company sent me several weeks ago the blank form of affidavit usually filled up by the attending physician, when an insured person dies. I was told that if I would answer the questions and make affidavit as to the truthfulness of my replies, I would be paid a certain fee. When I replied that Dr. So and So was the attending physician, and that I was merely the consultant, another letter was sent me, saying that my affidavit would probably do, and that if I would indicate in pencil my replies, I would be paid a certain fee. The fee spoken of in the second letter was twice that previously mentioned. Here again appeared to be an attempt on the part of a life insurance company to get a doctor to disclose confidential information about his patient; for neither letter showed that the relatives of the deceased desired my affidavit; and the unwillingness to apply to the attending physician, whose address I had given, awakened my suspicion. This suspicion was increased, possibly unjustly, by the doubling of the fee for the testimony; and how easily lead pencil replies could have been changed after I had sworn to the certificate!

Some doctors, it is believed, make a fee by accepting money from manufacturing drug companies for statements, certifying to the excellence of their secret nostrums. These certificates are then published and distributed as advertisements. It is probable that in some cases the doctor has had little experience with the vaunted remedy; in others he may use the preparation in his practice for a time and then write a hurriedly prepared clinical report detailing the wonderful results obtained. The latter method will undoubtedly bring a higher financial reward from the drug firm, for the report has the appearance of being a scientific investigation.

The editors of reputable medical journals have, I believe, been deceived at times by such literary outputs, and have printed these clinical experiences as original articles of real worth. The instigator of the supposed scientific test and the doctor, who has pocketed the fee, or bribe, from the exploiters of the synthetic compound or recently discovered alkaloid, probably smile at such innocence. The deceived editor and his thoughtful readers suspect the truth, however, when the writer orders many thousands of reprints of his clinical report, and the drug house fills the mails with "literature" testifying to the successful use of its products by Dr. Blank, whose hospital and professorial titles are conspicuously mentioned.

These bribes for suborned testimony need not always take the shape of cash. Liberal donations of drugs for the doctor's private sanitarium or hospital or a few cases of carbonated water for his private use, are perhaps offered and accepted as less likely to offend the sensibility of the professional conscience. Great, indeed, are the temptations of doctors who unite the running of a boarding house for the sick with the practice of medicine or surgery. Business methods are so different from truly professional methods that the necessary com-

bination in the conduct of a private hospital or sanitarium is liable to result in damage to the integrity of the latter. It is so easy to charge unnecessarily high rate of board and to advise patients, that a month's longer stay will be undoubtedly beneficial. Five or ten dollars a week added to the rate of board make it even possible to be liberal enough to charge no fee whatever for operative treatment. How generous this seems to the unsuspecting patient!

It is a question whether the testimony given in suits for damages against railroads and other corporations is not at times biased by the knowledge that the doctor will get no fee for his attendance, if the patient fails to "recover" for his injury. I was once asked to give a note saying that I was too busy to come to court to testify, because it was known that my opinion would be unfavorable to the cause of the plaintiff. Does any one doubt that, acceding to the request, would have rendered the payment of my bill more certain?

What is more despicable than the action of that operator who gets his patient ready for operation, perhaps even upon the operating table, and then declines to go a step further until the family or friends pay at once a fee for professional services. Patients' trickiness and unwillingness to settle just claims may almost seem to require this sort of shrewdness; but professional standards do not endorse it. Better is it to be defrauded than to resort to the methods of the road-agent and the black-mailer. One modern surgeon at least has suffered from reports, let us hope untrue reports, that he has used this method to collect his fees.

There has been developed of late a system of paying commissions to the family physician, who brings medical or surgical cases, to the consultant. Sometimes this takes the shape of agreeing to give the doctor, who succeeds in sending or bringing the patient to the operator or medical consultant, a percentage of the fee obtained for the operation or advice. At other times the iniquity of this arrangement is understood by both medical conspirators, and the family doctor is made a quasi assistant and is paid by the surgeon or gynecologist a part of the fee.

A recent investigator of this evil declares that he wrote letters to a number of well-known operators in a single city, asking whether they would give him a commission on patients sent to them. The number of affirmative replies was astonishing evidence of the extent of this criminal traffic in human suffering.

That his statement is not unworthy of confidence is shown by this extract from the columns of the *Journal of the American Medical Association* of February 2, 1901:

"Resolutions on Division of Fees.—The committee to whom was referred the resolutions of the Chicago Medical Society, January 23rd, met and adopted the following resolutions, which were recommended to the Society for adoption: 'Resolved, That the offering, or the giving of a commission, or percentage of a fee, by a consulting physician or operating surgeon, or the asking or receiving such a fee or commission in any guise whatsoever, by the physician referring the case, is dishonest, disreputable and unethical, unless such arrangement be

made with the full knowledge of the patient; Resolved, That a violation of this resolution shall subject the offender to expulsion from the Society.'

The resolutions were adopted unanimously by a rising vote. The Physicians' Club has passed a resolution to the same effect: 'Resolved, That the Physicians' Club of Chicago most severely condemns the seeking for or the receiving of a commission or part of a consultation or operation fee, as well as the offering or giving of a commission, or a part of a fee, as practices highly dishonorable and detrimental to the best interests of the medical profession.'

It is not the province of this address to elaborately argue against the propriety of such an arrangement, which tempts the family physician to look first, not to the welfare of the confiding patient, but to how the most profit may be made out of his ill health or accident; and which tempts the consultant to raise his fee to an extortionate figure, in order to divide with his "pal." The fact that such a commission arrangement is always concealed from the patient is a sufficient proof of its professional impropriety. The excuse given by the family doctor that the patient will pay a large fee to a consultant and leave his bill unpaid, is no adequate apology. It is the family doctor's duty to collect his bill by fair, not foul, means; and it is the duty of the consultant, it must be remembered, not to charge such an exorbitant fee that the patient's means are so exhausted that he cannot pay the doctor who has attended, and who is to attend, him.

Few consulting surgeons, I imagine, have not met this evil in some form or other. It may be a quiet request to add, to the consultant's fee, a certain sum "for me." It may be put in this wise: "Don't mention your fee, as being so much, before the patient; for I have told him it was so much, because I wanted thus much for myself." The latter admonition, after an operation done for a medical acquaintance, was my first intimation of a possibility of such dishonor in the profession. The doctor who called me in consultation subsequently became the president of his county medical society. I evidently had seen a side of his character which his colleagues had not had disclosed to them.

The family physician should, undoubtedly, charge more than his usual fee, when he meets another physician in consultation over his patient's case. The visit is longer than usual, more important than usual, and makes more demand upon the family doctor. He, therefore, should receive additional compensation. If he does not charge a proper fee under these circumstances and collect it, he is unjust to himself. It happens, however, not infrequently, that the general practitioner fears that the consultant will charge so much that he cheats himself, in order to be sure that the patient may have the advantage of the best consultant skill. It is to be regretted that the extravagant estimate, put by some consultants upon the value of their operative and diagnostic skill, justifies the fear that either the family doctor must go without proper compensation, or the patient lack the benefit of additional professional service.

Have we not all known of honorable and faithful physicians treating men and women in moderate

circumstances for practically nothing, and who, having called a surgeon or physician in consultation, have been shocked and astonished at the large fee demanded and even insisted upon? If the general practitioner grades his fee down to the financial condition of the sick or injured man, should not the consultant have a similar reasonable appreciation of professional humanity?

Put the case in another way. If doctors treat fellow members of the profession without fee; if they treat doctors' wives and children without charge, should they not be willing to operate upon, or see in consultation, without charge, a doctor's patient, when that patient is unable to pay? The logic seems irresistible. If the physician is worried and anxious about his case and desires advice from a man who has had more experience in that particular disease, it seems only proper that his brother practitioner should come to his aid as a consultant, for a small fee; or no fee, if none is obtainable from the patient. It is the bond of professional brotherhood that seeks to lessen the mental stress in both instances. Yet consultants have been known, I understand, to refuse to thus relieve the anxiety of a doctor, because the payment by the patient of a certain fee was not possible. There is little doubt that the family physician at times pays consultation fees out of his own pocket, in order to do his best for patients with whose straightened circumstances he is familiar.

Doesn't all Scotland know of Weelum MacClure's offer, when Sir George came to the Highlands to save the life of Tammas Mitchell's wife? and didn't Sir George do more honor to Medicine by his refusal to take the check of MacClure's partner in humanity than by his brilliant operation?

Some doctors of the 20th Century need to read that story again, before sending out their bills.

The consultant sometimes, in his anxiety for his fee, unjustly assumes that the family physician should play the role of collector, because the patient lags in the payment of the debt. I well remember the righteous indignation of a certain country physician, when, some years ago, he was almost dunned by a metropolitan surgeon, who found difficulty in collecting a consultation fee.

A trust, or at least a belief, in the "omnipotency of gold" seems to have debauched the professional spirit of these days. Perhaps, however, the doctors only breathe the same air and react to the same environment, as their business associates. The professional result, however, seems to the doctors of the school of ethics of Browne and Gale to be more deplorable than that exhibited in the ranks of trade. The chief end of business is financial gain; but the doctor should take "no cure in the hand for lucre or gaynes sake only." It is this different viewpoint that makes the "pursuit of avarice" in a doctor's work so objectionable.

Is it not true that doctors' bills against the estates of deceased patients are at times larger than they would have been for the same amount of medical attendance, had the sick man lived? Do not surrogates and orphans courts act justly in viewing with suspicion the large bills sometimes presented for adjudication? Is there no reason for thinking that some medical men are willing to charge a larger fee than their custom, when they know that

dead men can neither complain, nor confer future benefit by contracting bills for medical service?

I recently heard of a doctor replying to a criticism that his bill against the patient's estate was too large, by saying that he always charged more when the patient died, because the death hurt his reputation! Such reasoning must be very soothing to the surgeon who has a fatal result to bewail. If carried to its legitimate conclusion, the argument would indicate that the justifiability of an operative procedure should be decided by the ailing patient, and the work done by a surgical engine without soul, conscience or heart. Then would Petrarch's innuendo that physicians trifled with human sickness for game and mercenary gain be justified (Medical Economy during the Middle Ages. Fort, p. 428); and the boy's objection to becoming a doctor because "he couldn't kill a cat," seem a valid reason for adopting another means of livelihood.

It is scarcely to be doubted that the triumphs of modern medicine and surgery have turned the heads of some practitioners, and that charges have become so large in certain instances as to be properly dubbed extortionate. The chronicles of the Middle Ages show, according to Fort (p. 461), that recourse to saintly remedies was induced by the excessive demands of the doctors, by which entire patrimonies were frequently swallowed up before recourse was had to these ecclesiastical curative agencies. Uncommon pharmaceutical compounds or double doses were prescribed as necessary medicaments, when the patient was wealthy, while for the poor the smallest dose was considered sufficient to cure. Do not these records afford food for thought on the relation of professional fees in this decade to the Christian Science Healer, to Hospital Abuse, and to the Gold Cure for Inebriety?

The medical professors of the Middle Ages are said to have been able to dictate terms, because "affluent invalids readily believed it impossible to escape death" unless attendance by these eminent doctors was secured. Do we not see evidences of this morbid belief, at the present day; and is not its abuse advancing "practitioners rapidly to enormous wealth and pomposity?" (Fort op. cit. p. 428).

Does any member of this Society really believe that eight thousand dollars or ten thousand dollars is a just fee for the performance of any possible gynecological operation, done on a private citizen, even if he be a multimillionaire? By a fee for the performance of an operation, I mean the charge for the operation alone, not including the preparatory treatment, the after-treatment, the nursing, or the hospital private room. I admit the possibility that the national importance of the patient, a ruler for example, might increase the surgeon's responsibility so much that this enormous fee might be justifiable. Under other circumstances its propriety is scarcely conceivable.

Would any one present to-night justify the action of a surgeon, who when asked for his bill, said "I send no bill, but I get for such professional service from five hundred to ten thousand dollars?" This is the attitude of the negro porter on the sleeping car, who, with a scrape of his foot, says to the man whose hat he has brushed, "Gib me what you please, sah;" because he hopes to get a half dollar for ten cents' worth of service. This attitude may

not demean an ex-slave, but it does not seem worthy of a medical gentleman, does it?

If such fees are to be asked by the medical gentlemen of to-day, the patient certainly ought to be frankly apprised of the fact, before he is allowed to incur the debt. I know of an instance where a physician of eminence was requested to come to a distant town to see a patient in consultation; a telegraphic reply was promptly sent, "My fee is three hundred dollars, shall I come?" I have but little criticism to offer to this frank mode of action. It is a different thing when a patient with trusting confidence submits to the professional offices of a doctor, and receives a bill of such proportions that it takes years of self sacrificing economy to discharge the debt.

There is, it seems to me, one just plan by which fees should be regulated. It is that the doctor should have an estimate of the value of his services, operative or otherwise, fixed in his mind. The amount should be based on his experience and skill. It should not be so low as to coax away unjustly the patients of the younger and less experienced men of the profession. This fee should be lessened when the financial position of the patient would make its payment a serious burden. It is not professional or humane to take a man's income for a whole year, to pay for the doctor's bill of a month.

A well-to-do patient should pay the full fee, which should be generous in order to recompense the doctor for his expensive education and hazardous life. This fee, however, should not be increased because the services of the doctor are utilized by a very wealthy person, unless an unusual time is given to the service or additional responsibility is placed upon the physician by reason of the man's position.

"Make it up on a rich patient," or "Charge him a big fee, because he is a millionaire," are admonitions not to be heeded by the true physician; but only by that healer of men's ills who is but "lightly dipped in generous honesty and faint hearted in integrity." Such words may do for the motto of the man who is "couetous or craftie sekyng his owne lucre, before other mennes health succour and comfort," but not for the doctor who taketh "the cure in the hande" for "an honest and competent rewarde with a Godly affection to doe his diligence."

THE ETIOLOGY OF ARRESTED MENTAL DEVELOPMENT.

BY PEARCE BAILEY, M. D.

of New York

Attending Physician to the Alms House Hospital, New York

Idiocy, imbecility, and feeble-mindedness are varying degrees of the same condition. So gradually do they merge into one another that it is impossible to say where the one begins and the other ends. They all are the psychological expressions of infantile cerebral pathology. Their causes, therefore, which include all factors that interfere with the development of the brain of the child, must be considered together. For the purpose of brief reference, they are best divided into,

1. Those occurring before birth.

2. Those occurring at birth.

3. Those occurring during infancy and childhood.

1. *Prenatal Cause.*—More than fifty per cent. of all cases of idiocy and feeble-mindedness are congenital, and in a large proportion of this number, defective nervous systems on the part of parents or near relatives, is demonstrable. Statistics as to exact proportions vary greatly, and it seems to me fruitless to attempt to harmonize them. All agree that bad nervous heredity is the most conspicuous inhibiting factor to the growth of the infantile brain, and daily observation shows that idiotic and feeble-minded children are the products which are to be expected from marriages in which one or both parents carry in their blood the taint of degenerative nervous conditions. In comparison with this cause, all others sink into insignificance. So that in studying the etiology of idiocy, we must begin with the causes of degeneration.

Degeneration, which endangers the capacity of the individual to beget normal descendants, may be a result of ancestral defects, or may be acquired. When inherited, it is the insane, the hysterical, the alcoholic, the epileptic, the exhausted, and the defective generally who transmit it. Of all degenerative conditions, mental enfeeblement is the one in which direct inheritance is the most frequently demonstrable. Profound idiots are sterile. But in the lesser degrees of idiocy, and in imbecility and feeble-mindedness, either parent may, unfortunately, be capable of procreation.

In a large proportion of cases in which one parent is idiotic, the child bears the identical stigma. Direct inheritance in idiocy is more frequent than in other degenerative conditions. The child of an insane mother may become alcoholic and be sane, or the child of alcoholic inheritance develop any degenerative nervous disorder; in such cases the neuropathic constitution is inherited, but the particular type of its manifestation is decided by environment or other conditions. But with idiotic parents the rule is that the type itself is perpetuated.

It may seem that child-bearing idiots and imbeciles are not numerous enough to demand close attention. Such, however, is not the case. The commissioners appointed to inquire into the state of lunatics in Scotland ascertained that the number of idiotic women who had borne illegitimate children was 126—one mother having born five children.

Feeble-minded women are easy prey to the lust of men. When lacking natural or State protection, therefore, they are extremely liable to increase the State's dependents. They are also particularly subject to infection from venereal diseases. They thereby doubly disseminate the factors of degeneration. To protect this class and the consequences of it, there was established at Newark several years ago, the New York State Custodial Asylum for Feeble-minded Women. This institution shelters, during the child-bearing period, over four hundred feeble-minded women who lack natural protectors. By thus forcing sterility on these unfortunates, the State serves them, and at the same time serves a very vital economic purpose of its own.

In acquired degeneracy, it is assumed that the individual is born normal, but that through various

or abuse he has lost the power of procreating normal children. Prominent among the causes of acquired degeneracy are tuberculosis, alcoholism and syphilis.

Tuberculosis in the parents as a cause of degeneration is well recognized. As a cause of idiocy, it does not seem to receive the attention it merits. Yet it is a most important one. Piper found tuberculosis in the parents and near relatives in 23% of his cases of congenital idiocy, and a large proportion of the deaths among idiots is from phthisis.

Alcohol is the most important factor in acquired degeneration. The disastrous effect of alcohol upon the developing egg has been proved experimentally. Féré found that the injection of a few drops of an alcoholic solution beneath the shell was followed by a great variety of developmental defects. It is rather difficult, however, to determine the relationship in which idiocy and alcoholism stand to each other. Drunkenness of a parent at the time of conception has long been regarded as a fertile cause of imbecility. "Young man," said Diogenes to a stupid boy, "thy father must have been very drunk when thy mother conceived thee." My experience teaches me that the drunkard is *per se* a degenerate; that the acquisition of an uncontrollable alcoholic habit is in itself a sufficient indication of an enfeebled or perverted nervous system.

When, therefore, the child of a drunkard turns out feeble-minded, it seems as though there may well have been a cause antedating the alcoholism. Certain it is that alcoholic persons are frequent among the forbears of idiots. Ireland, in his "Mental Affections of Children," expresses himself as believing that "idiocy is not the ordinary legacy which drunkards leave to their children." I think this view is correct. In my experience the child of the drunkard is apt to have a nervous system of poor resistance and great excitability. Epilepsy, chronic chorea, morbid impulses, and bad habits frequently overtake him. These affections, rather than primary idiocy, seem the common legacies of alcoholism. They may well bring all varieties of mental defects in their train.

Active syphilis in one or both parents is reflected in the offspring. It is a fertile cause of miscarriage. Most children born actively syphilitic die soon after birth. Hereditary syphilis also causes organic brain disease in infants and young children—and organic disease of a developing organ, even without such gross lesions as hemorrhage, etc., precludes perfect development.

The question is more difficult when it concerns the responsibility of a parent who has had syphilis, but who has been free from all active manifestations of it for several years before the conception of the child. The existence of a parasymphilitic toxin is as well established as a non-demonstrated theory can be. But, so far as we know, this toxin acts solely on the nervous system of the patient himself, as, for example, in locomotor ataxia. Proof that it can act directly upon the egg is wanting. We all know fathers and mothers who have had healthy children, yet I doubt if any of us know an idiotic or feeble-

minded child of whose imperfect mental state parasymphilitic poison is the only possible explanation.

The causes which have been mentioned are the chief ones which impair the power of parents to bring forth healthy and resistant children. They occupy first rank by reason of the frequency with which they can be demonstrated throughout the neuropathic class. The more massed the parental degenerative factors, the more certain it becomes that the child will not escape his birthright. With both parents tainted, the hopes of normal issue are slight. By the continuous intermarriage of degenerates, degeneration progresses till it results in extinction of race. It is through the propagation of stigmata that consanguineous marriages have obtained their bad name.

The most far-sighted optimist cannot make out the dawn of the day when inherited degeneracy shall cease. But it does not require a very wide excursion of the imagination to discern conditions under which it might be materially curtailed. For one thing, society may well be expected to some day place importance upon the eligibility of persons who wish to marry. As it is to-day, it puts few obstacles in the way of the most improper alliances. I know many excellent families which have sanctioned marriages of their daughters with confirmed alcoholics. It was said that matrimony would work reform. The clergy take little or no care to ascertain the parental fitness of the couples they join in wedlock. The opinions of physicians are only occasionally sought by prospective brides and bridegrooms. And physicians' warnings are generally disregarded. Physicians themselves are not altogether free from blame in these matters. It is as much their duty to investigate the marital fitness of their patients as it is to discover the nature of a disease. And their warnings to the matrimonially inclined degenerate should be given with the same emphasis and the same conviction as they would be, were the object the deterring of the syphilitic patient from sexual indulgence, or the epileptic from alcohol. Two cases have come to my notice in which physicians with full cognizance of the facts, so far outraged their scientific knowledge as to contract marriage with epileptics.

The eradication of degeneracy has its brightest hope in increased education and better State care. Teach boys and girls physiology, and young men and women the pathology of generation. This is a step not difficult to accomplish, and would provide a certain protection to the normal. For the abnormal and degenerate, sequestration is the only solution. For advanced cases, institutions are the legitimate homes. But for borderland cases, for the feeble-minded, the half insane, the drunkards, the tuberculous, the epileptic, colonization is the surest means of caring for the future.

As is well known, this idea is receiving more and more approval. It should be developed, enlarged and propagated. The Craig Colony for epileptics and the institution at Newark, N. Y., have demonstrated their usefulness. The colony system for the insane is being gradually extended. The State Hospital for Consumptives is an established fact. As yet there is no colony for alcoholics. To protect itself against them the state is still powerless. However dangerous a drunkard may be to the

actual community, or to communities yet unborn, the moment his liberty is threatened he raises the cry of "inalienable right" and is free. Yet the time must come when chronic alcoholism shall be placed within the pale of State control, and when alcoholics shall be sequestered on farms on which there is a rigorous quarantine against alcohol.

Brief mention will suffice for the other prenatal causes of feeble-mindedness. They are chiefly maternal. Diseases of the mother occupy a place of importance. Of them, diabetes is one which should be regarded as a moral disqualification for conception. Popular tradition attaches much significance to a variety of other factors. Fright, grief, and similar violent emotions, traumatism, unhygienic surroundings, are all from time to time invoked as explanations of feeble-mindedness in a child. Of prenatal causes referable to the fetus may be mentioned the various fetal diseases and twin pregnancy.

II. Causes Acting at Birth.—The various factors which complicate delivery stand in prominent relationship to idiocy and imbecility. Cerebral injuries incurred at this time may cause gross lesions, which naturally imperil the development of the intellect. The commonest clinical manifestations of such injuries are diplegia and paraplegia. Even when clinical evidences of such gross lesions are absent, difficult labor with the attendant compression and asphyxiation, is sometimes the only discoverable cause for feeble-mindedness. In support of this is the fact that first children are much more apt to be feeble-minded than later ones, and that boys are affected with nearly twice the frequency of girls.

The proper use of the forceps in delivery should be regarded as a means of avoiding brain injury, rather than a cause of it, as the dangers of skillful extraction are less than long continued pressure on the head. Nevertheless, the use of forceps, by a reliable practitioner, is in itself an indication that delivery was difficult, and consequently not without danger to the head of the child.

III. Causes acting after Birth.—The study of the post-natal causes of idiocy is the study of pediatrics. All causes, whether they be traumatic, toxic, or nutritional, which act on the developing infant brain, fall into the rubric. But unless they be definite, quickly acting, and with evident and immediate results, they are extremely difficult to define and to evaluate.

If a child's development is arrested consecutively to a serious head injury, or to an attack of convulsions, or unconsciousness followed by hemiplegia, or to an attack of scarlet fever, the immediate cause is easily understandable. But when the evidences of retardation follow no such crisis diagnosis is much more elusive.

In the child at birth consciousness is not yet awakened, and all nervous phenomena are essentially reflex in character. In the absence of physical deformities if the child sleeps and nurses well, as feeble-minded children often do, it is impossible to decide as to mentality during the first two or three weeks of life. The child is usually several months old before it is brought to the physician by the mother, who is becoming alarmed. She has at last

observed that the baby's attention is not attracted by moving objects, by lights or sounds, that it does not follow with its eyes, that it is heavy and inactive, and unlike other children. It is practically impossible to determine whether such slow developing symptoms are post-natal in their causation, or whether they had their origin before birth. As an example may be cited cretinism, developing in early infancy. No one can say whether such cases are congenital or acquired.

Whenever the causes first begin their action, it must not be forgotten that they exert their influence on an organ with its future all before it.

At birth the fibers of the infantile brain are only partially medullated. Its cells are comparatively few in number and of imperfect development, as is shown by their great irritability. It resembles in its function a primitive nervous ganglion more than it does the adult encephalon. From the simplicity of its structure and from its hyper-excitability, causes which leave the adult brain undisturbed, exert intense impressions upon the brain of the child. Anyone, for example, who has witnessed the profound cerebral symptoms in very young children which may result from intestinal disturbance, will not question the extreme susceptibility to poisons of the child's ganglion cells. As in all low forms of life, also, the infantile brain is extremely susceptible to reflex stimuli. Severe nervous storms result in infants from slight peripheral irritations. But the period which is that of the brain's greatest susceptibility, is also the period of its greatest growth. At the end of the second year of life the brain weighs three times as much as it did at birth. With such rapid workmanship on the structure which is to be the permanent home of the intellect, every moment is precious. Interruptions to progress, even though brief, may have far reaching results.

Still another factor in infantile pathology, which gives an added importance to cerebral disorders, is the tendency for focal lesions to affect the whole brain. In the adult brain, focal lesions may come, and remain, or go away, exerting only a temporary effect on intelligence. I have reported the case of a man who had suffered total destruction of the frontal lobes of one side, with atrophy of the rest of the hemisphere, without the slightest disturbance of intelligence. During infancy and early childhood, however, no lesion is too small or too circumscribed to affect the whole encephalic mass or to inhibit its growth. This fact creates the greatest difficulty in the diagnosis of cerebral diseases in infancy. These disorders are characterized by the general symptoms of cerebral trouble, such as convulsions, or coma, or irritation, or vomiting; only occasionally is the most painstaking examination rewarded by a definite focal sign. Thus clinical behavior and ontogenesis go hand in hand. The brain of the infant is too undeveloped to permit of true focal disease.

With so delicate, easily influenced and rudimentary an organ as the infantile brain, therefore, causes which seem trivial, may be none the less active in arresting development. Only some of the most important ones can be touched upon here.

A foremost place among them is occupied by diseases of the brain and its membranes. Cerebral

or meningeal hemorrhage is not rare in infancy and early childhood. It becomes less frequent after three years of age. In the early cases, that is, before two years of age, the resulting idiocy is profound. Older children sometimes escape with little or no intellectual impairment, and in older children, if mental defect occurs, it is usually manifested as feeble-mindedness merely. All varieties of meningitis also are fertile causes. It is to be remembered that sporadic and epidemic cerebro-spinal meningitis are not rare in infants and young children.

Of the infectious diseases, scarlet fever and typhoid fever are the ones most frequently mentioned as entailing mental deficiencies in children. To these must be added the intestinal disturbances which form so important a chapter in infantile pathology. The cerebral manifestations of these intestinal intoxications are extremely diverse and serious. Convulsions, coma, all forms of jerking movements, rigidity of the muscles of the neck, strabismus and similar symptoms result from them without any gross lesion in the brain. If temporary, the results may not be serious. But if continued as they sometimes are, over days and weeks, it is difficult to believe that they do not interfere with the normal development of the brain.

The subject of infantile convulsions is too extensive to receive more than the most cursory mention in a paper of this character. It is, however, too important to be passed over without a word. Many children pass through all the trials of infancy and childhood without convulsions. Many of those who have them, grow up into normal people. But in some children, convulsions ensue upon the slightest provocation. Of these children a certain proportion become confirmed epileptics. And as epilepsy developing in infancy and childhood is almost invariably associated with intellectual defects, this question has important bearings on our subject. Now, when epilepsy develops in adults, it is only very rarely that the trained and wide-minded observer can be convinced that it is of reflex origin. But in infants and young children the case is different. They are essentially reflex organisms and respond vehemently to peripheral stimulation. There is no doubt whatever, that convulsions in children may be the direct consequences of such peripheral irritations as worms, phimosis, constipation, dentition, adenoids and the like. It may well be that the nervous organization of such children is more excitable than normal. It is none the less true that the convulsions often cease when the irritation is removed. If convulsions recur with sufficient frequency, the reflex arc becomes so well travelled that the child forms the epileptic habit until finally the fits take place without discoverable cause. The disease, though originating peripherally, would eventually be called idiopathic epilepsy. Now idiopathic epilepsy is a disease which is considered par excellence as a child of the neuropathic family. All statistics place it high in the list of nervous diseases in which degenerative stigmata have occurred in near relatives. Yet in a certain number of cases the family record is clean. Now I am of the opinion that in many such cases the disease had a peripheral origin in infancy. If this opinion is correct, it carries with it an important moral in the

matter of the treatment of infants and young children of excessive reflex excitability.

Sensorial idiocy is the variety of mental defect brought about by the loss during infancy or early childhood, of one or more of the special senses. It is limited almost exclusively to sight and hearing.

The deprivation of these means of education necessarily implies that fundamental conceptions supplied by them can never be acquired. Without special instruction, the mental horizon of children so afflicted is necessarily limited. Such women as Laura Bridgman and Helen Keller are brilliant examples of what skillful and painstaking instruction can do. It cannot be said that such persons are feeble-minded, but it cannot be gainsaid that they are defective. Loss of hearing affects the minds of children more than loss of sight. The cranial capacity of deaf mutes is below that of hearing children. Also mental culture in the average deaf mute cannot reach such a high point as in the hearing child. In disposition, also, deaf mutes are less pleasant and less trustworthy.

With slight degrees of sensorial defect, children can usually be well educated and be normally developed. But even in them one can hardly expect the full mental unfolding that might have been looked for had the child not been hampered in the acquisition of its ideas.

In addition to the mental defects caused by total blindness or total deafness, imperfections in the special sense organs of sight and hearing may so much interfere with the education of a child that it gets the name of being a backward child. This is especially true of hearing. Even slight imperfections in hearing may seriously interfere with the child's education. It is needless to say that in very young children, partial deafness is a very difficult thing to discover. Errors of refraction and muscular insufficiencies always put obstacles in the way of the development of the intelligence. It so frequently happens that children with these troubles do not learn to spell well, that some authorities maintain that in nearly all children who are conspicuously bad spellers some ocular imperfection may be demonstrated.

Traumatisms play so small a part in the causation of feeble-mindedness and idiocy that I shall pass them over. But I cannot bring this paper to a close without some mention of the nutritional disturbances by which the brain of the child is interfered with in its development.

A large number of feeble-minded children are rachitic. From the frequency with which rickets attacks the cranial bones, there was long thought to be an intimate connection between the local bone disease and the defective intelligence. There may be, but to my mind the relation between rickets and faulty brain development is better to be explained by disturbances of nutrition in the developing ganglion cells, than by any local process of pressure, irritation or anemia. A rachitic pelvis is due to the bones not being properly supplied with essentials at the time they need it most. And idiocy or feeble-mindedness in a rachitic child finds its best explanation in under-feeding of the ganglion cells at the time of their greatest growth.

In malnutrition, both when arising from improper

food and poor hygienic surroundings, and when arising from poisons circulating in the blood, are to be found the origin of many cases of defective brain development.

Some of the acute nutritional and toxic influences have been mentioned under infectious diseases. Here must be added some which act more slowly.

In amaurotic family idiocy, which usually makes its appearance between the second and eighth month of extra uterine life, there is a visible degeneration throughout the whole nervous system. No satisfactory explanation of the pathogenesis of this disease has yet been offered. But it must result from toxic or nutritional causes. We have learned something about the pathogenesis of cretinism, but we are far from knowing why the thyroid secretion disappears. It is interesting to note in this connection the case of Shield's (*New York Medical Journal*, 1898, No. 13), in which a child ten years old, had an attack of acute thyroiditis with fever. Subsequently the thyroid atrophied and cretinism developed.

As to external poisons, alcohol is the only one I shall mention. Difficult as it is to believe, chronic alcoholism and its effects in infants and very young children, are more and more frequently heard of. It comes about from the parents giving beer and wines to their little ones, and from medicines given in alcoholic solutions.

In closing, I wish to express my appreciation of the inequality in point of frequency and importance, of the causes which have been mentioned. Some of them are very rare and are significant in gross totals. Others merit much more detailed description than the limits of this paper would justify. But all have this in common, that the study of any one of them, whether frequent or infrequent, teaches important lessons to those who wish to have children, and to those whose duty it is to care for them.

CATARACT EXTRACTION.

By EDWARD JACKSON, A. M., M. D.,

of Denver.

Ophthalmologist to the Arapahoe County Hospital, consultant in ophthalmology to St. Anthony's Hospital, Denver; Emeritus Professor of Diseases of the Eye in the Philadelphia Polyclinic.

The following series of recent cases, although a small one, illustrates as well as could large numbers, the more important points regarding cataract extraction, as it is now resorted to and executed.

CASE 1.—L. G., a colored woman aged 70, has been slowly losing her sight for some years. The right eye still counts fingers at four feet. The left can just perceive movements of the hand in front of the eye. In the right, there is a nuclear cataract so far advanced that no fundus reflex is visible. The left presents a hyper-mature, white, slightly shrunken cataract. The anterior chamber is of moderate depth; the tension of the eye normal. The pupils are normal in reaction and of moderate size. Fields of vision apparently normal, with good quantitative perception of light.

March 6, 1900, extraction was done on the left eye with a small iridectomy, because the prominence of her eye and the thick powerful lids of a colored person increased the risk of iris prolapse after simple extraction. The incision was made just within the corneal margin. The capsule was opaque, opposite the lower portion of the pupil; but immediately after the operation the patient could count fingers. Four days later, the anterior chamber had begun to reform, showing that the wound had closed; and next day it was of full depth. The patient was allowed to sit

up on the fourth day and the dressing omitted from her right eye.

Recovery was somewhat slow, but uninterrupted. At the end of six weeks she had vision of 4-20 mostly. I then did a needle operation, incising the capsule in the form of an inverted T. A week later the eye was entirely quiet, and with -12.5 -3 cv. ax. 145° vision equal to 4.6 mostly. Three months later vision had risen to 4-5 full.

CASE 2.—B. W., a man aged 81, has been unable to read for 5 or six years, his sight having begun to fail some years before that. The right eye was first affected. Vision is noticeably worse now than a year ago. There is good quantitative perception of light in the left eye and fair in the right; with good fields. The pupils react slightly to light, the right being 3.5 mm. and the left 2.5 mm. in diameter. They are very dark gray, the color of the pupil in many old people who retain good vision; but no fundus reflex can be obtained with the ophthalmoscope. Tension of the eyeballs normal; anterior chamber deep. He has a habit of squeezing the lids tightly together, and does so whenever they are touched. He had a slight chronic catarrhal conjunctivitis, for which he was treated a few days with applications of silver nitrate solution.

June 20, 1900, simple extraction was done on the left eye, at St. Anthony's Hospital. The incision in the corneal margin was of full size, including almost half of the cornea. The lens proved to consist of a large, hard, dark brown nucleus, with only a trace of cortex. The pupil was left clear and central, but distorted by the stretching of the large nucleus. Pilocarpin, 1 to 20, was used to contract the pupil. The dressing was omitted from the right eye on the sixth day, and from the operated eye, during the daytime, on the eighth day. No sign of the anterior chamber having reformed was noted until the tenth day. It was again quite empty on the eleventh day, and a small prolapse of the iris occurred at this time. The wound had closed and the anterior chamber was fully reestablished on the fifteenth day. On the seventeenth day the patient went home to Julesburg.

October 5, he returned, the eye being entirely quiet. The ophthalmometer showed an astigmatism of 10. D. With -8 equal to -7 cy. ax. 170° , vision equal to 4.8 partly. The only trace remaining of the prolapse was a moderate lengthening of the pupil upward, and a small pigment spot near the centre of the firm corneal scar.

CASE 3.—C. S., a man aged 28, two years ago was struck in the right eye by a small flying fragment of rock, which caused no bleeding or subsequent inflammation. A year ago he noticed that "something was growing over the sight of the eye." Vision is now reduced to counting fingers at ten inches, while in the left eye vision equals 4-5. There is no scar, no adhesion of the iris. Tension of eyeball normal. The right pupil is occupied by white lens opacity, but not of a uniform milky appearance. Under cocaine the pupil dilates to 8 mm., but its periphery is occupied by hazy lens. There was slight conjunctival discharge, which disappeared under the protargol solution.

August 28, 1900.—I removed the lens from the right eye by simple extraction. The nucleus proved to be as large and firm as the average at 50 years of age, and was delivered with some difficulty through what was practically a 3 mm. flap incision in the upper corneal margin. The iris prolapsed and had to be returned with the spatula, but after that the pupil remained central and round. Eserin was instilled and both eyes closed with a simple dressing. At the end of 32 hours, the anterior chamber was fully reestablished.

August 30.—Eserin was used for the last time and the dressing was omitted from the left eye.

September 1.—Hydrocyanum was instilled and next day the pupil was well dilated, showing numerous gray masses in the capsule, with a clear space above them.

September 3.—All dressings omitted.

September 7.—Patient came to the office, and the ophthalmometer showed 5. D. of astigmatism, axis of convex cyl. at 30° .

April 9th, 1901.—With -13.5 equal to -0.50 cyl. ax. 35° vision equal to 4.9.

CASE 4.—J. C. F., a man aged 75, began to wear glasses at 45, and between 50 and 60, he got his "second sight," so that he could read without glasses. But for three years vision has been failing. He can still see pretty well in the periphery of the field, but in each eye central vision is reduced to counting fingers at one foot. He has flashes of light before the left eye and sometimes dark specks floating

in front of it. The tension of the eye-ball is normal. The fields of vision are apparently perfect, and there is good quantitative perception of light.

September 15.—I did simple extraction on the right eye. The globe was rather collapsed and soft from cocaine. The lens proved to be chiefly a yellowish brown, hard nucleus. After its removal the patient said that everything looked blue, except at the centre of the field. The pupil contracted well under eserine, and remained central and circular. Both eyes were closed with a simple dressing. At 56 hours the anterior chamber was of full depth. The pupil was occupied by gray cortex; and he saw no better than before the operation.

September 19.—The dressing was omitted from the left eye, and after this no eserine was employed in the right.

September 22.—Instilled a mydriatic.

September 24.—All dressings omitted. Complaints of aching and pain in the eye, probably from rubbing of scar against the lid. Eye free from hyperemia, except in the region of the scar.

October 2.—Came to office; eye quiet and free from pain. The ophthalmometer shows 9 D. of astigmatism.

October 11.—Some reflex is visible in the right pupil, and he thinks his vision has improved in the last few days; but it is still limited to counting fingers within two feet. I did a needle operation, incising the capsule on the lines of an inverted V. A simple dressing was used, until the next day. Four days later, the eye was free from hyperemia, and with $-1/8$ equal to $-1/4$ cy. ax. 5° vision equal to 4.12 partly.

November 23.—He was given right $-1/9$ equal to $-1/2.5$ cy. ax. 10° , which gave vision 4.6 partly, and $-1/3.5$ spherical was added for reading.

March 6, 1901.—His vision with the same glass is 4.5 mostly.

CASE 5.—E. K. B., a woman aged 68, always near-sighted, had noticed her vision failing for several years. She had suffered from apoplexy four months previously, a right hemiplegia but no aphasia, followed by complete recovery. The fields were good and central vision; right, 4-80, left 4-20 mostly, with correcting lenses. There was general haziness of the right lens with streaks of cortical opacity. In the left there was a dense posterior polar opacity. A few days after I first saw her, she suffered a severe attack of angina pectoris, with very great disturbance of the circulation, after which her general condition slowly improved. At the end of three months her vision was reduced to: Right, counting fingers at 1 metre; Left, 4-30.

October 22.—I did simple extraction. The incision was placed slightly beneath the conjunctiva. The nucleus was large, and considerable clear cortex was scraped away in expelling it. The iris settled back without stroking. Eserine was instilled and a simple dressing applied to both eyes. The operation was done in the morning, with the patient sitting in an easy chair; and she was kept in this chair until evening, and then put to bed with the head considerably elevated, to diminish the risk of hemorrhage. At the end of 33 hours, the anterior chamber had reformed, but was still shallow. It did not, however, re-open, and two days later was full of depth.

October 24.—Eserine was omitted; and the next day a mydriatic was used. On the seventh day she complained much of the feeling of a foreign body under the under lid, probably from bulging of the scar. Up to this time there had been a good deal of swelling of the conjunctiva; but it was now diminishing.

November 10.—She came to the office. The corneal astigmatism amounted to 7 D.

November 28.—She was given distance glasses: Right $-1/7.5$ equal to $-1/4$ cy. ax. 17° . Vision equal to 4.5.

January 17, 1901.—The strength of the cylinder was diminished to 3.5 D., giving vision of 4.4 mostly.

CASE 6.—L. M. L., a woman aged 60, who four years ago suffered from a very severe iritis in the left eye, with a history of preceding slight traumatism, but no perforating wound. At this time she was seen by five oculists, and was under treatment for 9 months. She was advised by three of them to have the eye enucleated. But this eye finally became quiet and has shown no relapse since. Last July, the right eye became inflamed and was sore for two months. The inflammation followed exposure to cold and wet. She has always been near sighted. Could read some with the right eye after the left was first affected. But vision has gradually failed ever since. Now the right counts fingers at three feet, the left counts fingers

held within three inches of the eye. Right pupil is oval, long axis vertical, and reacts fairly to light. The iris is normal in appearance, but shows three broad posterior synechiae, when the pupil is dilated. There is general haziness of the lens, but the fundus reflex can be detected throughout the pupil. Tension of the both eyes about normal December 10.—The right was extracted, without iridectomy. It was almost entirely nucleus, brown, hard, 4 mm. thick, and 8 mm. in diameter.

December 15.—A small incarceration of the iris occurred; the anterior chamber was re-established, and there was mild iritis. From this time on there was a slow iritis, attended with moderate hyperemia, very little pain and no tenderness of the eyeball; but with considerable exudate into the pupil. Not until the last of January did the eye become free from hyperemia, and then vision was no better than before the operation.

February 10.—A needle operation was done, giving a very small, clear pupil, but permitting considerable retraction of the iris. At first there was very little reaction, then an iritis occurred, slowly increasing for two weeks, after which it slowly yielded. But the eye was not free from hyperemia, March 9, when the patient had to leave the city for her home in Wyoming.

When first tested with the ophthalmometer, January 13, her astigmatism was 3 D., when last seen it had diminished to 2 D., with the axis at 30° and with $-1/12$ sp. vision equal to 10-200.

CASE 7.—T. B., a man aged 48. Sight in the left eye has been failing for 3 years. He is a miner and his eyes have frequently been struck by pieces of flying rock; but have not been severely injured, and no scar can be detected. The vision of the right eye is normal. The left has good light perception, and good field. Tension normal in both. The left pupil is occupied by grayish white opacity; which is almost uniform, but on examination proves to be entirely so. The pupil reacts normally and the anterior chamber is very deep. He has a pterygium 5 mm. wide, extending 3 mm. on the cornea at the nasal margin.

March 2, 1901. I did simple extraction on the left eye at St. Anthony's Hospital. The incision included the upper third of the corneal margin. The nucleus was found as large laterally, but not so thick as the average senile nucleus. It was thinly covered by soft cortex. The incision having been planned for a smaller nucleus, there was some difficulty in expelling the lens. It was immediately followed by fluid vitreous, 1-6 to 1-4 of the vitreous being lost. Eserine was instilled and the simple dressing applied to both eyes. At the end of 30 hours the anterior chamber was of full depth; the eye was free from pain, and the sound eye showed as much hyperemia from bandaging as did the eye operated on. The wound did not reopen. Eserine was omitted on the third day, and atropine instilled on the fifth. All dressings were removed on the seventh day; and on the ninth day, the patient left the hospital. His astigmatism, as shown by the ophthalmometer, was 7.5 D.

March 18.—The eye was quiet and with $-1/8$ equal to $-1/4.5$ cy. ax. 155° vision equal to 4/10.

Senile Cataracts at the Age of Fifty.—The above histories indicate sufficiently the common details of such cases. In a general way they may be classed as cases of senile cataract, although two of the patients were under 50. In these two the cataract was probably of traumatic origin. But the regular operation for senile cataract was required; and even with this, the attempt to reduce slightly the size of the corneal incision added to the difficulty of the operation. In these cases the pupil presented a white and almost uniform appearance, so that my first impression was, that I had to deal with fluid cataracts. Closer examination, however, showed that the opacity was not perfectly uniform in color. The operation, therefore, was planned as for ordinary senile cataract and the conditions developed by it fully confirmed its necessity.

In extracting non-traumatic cataract in young persons, I have a few times found the lens so soft that it could have been expelled through a much

smaller incision. But more frequently, as in these two cases, any decided reduction in the size of the corneal incision increased considerably the difficulty of expelling the lens, and I have known operators of large experience to be completely balked by the large size of the nucleus encountered in comparatively young persons. When a cataract in a young person is directly traceable to a wound penetrating the lens, we may hope to find the lens largely composed of soft cortex. But when, as in these two cases, the cataract follows obscure disturbance of the lens nutrition, the condition seems to be more one of premature senile change, including the enlargement and rigidity of the nucleus, that commonly occur in later life.

Mature Cataracts.—Cases 1, 3 and 7 were of mature cataract. The first and last even somewhat hyper-mature. Case 2 was one of the slow cases. It had been progressing 10 or 12 years and was still advancing. Although the power to read had been lost for 5 or 6 years, the appearances presented by the lens were not those of mature cataract. The patient had, however, reached an age when the lens is wholly converted into firm nucleus. It came away in a single mass, giving immediate restoration of vision, so that fingers could be counted at once, and vision of 4-8 partly was obtained without any secondary operation.

Extraction of Immature Cataracts.—In cases 4, 5 and 6, immature cataracts were operated upon. In 4, although the central vision was reduced to counting fingers at 1 foot, the cortex was clear enough to permit a fair fundus reflex, and peripheral vision good enough for the patient to get about some alone. In cases 5 and 6 fingers could be counted at 3 feet. So immature were 4 and 6, that the extraction operation alone gave no improvement in vision. So much clear cortex was left behind, to become opaque in a few days after the operation, that it interfered with vision as much as did the original cataract.

These cases illustrate fully the the disadvantages of operating on unripe cataracts, and they give an opportunity for comparing these disadvantages with the gain which justifies such operations. The patient gained no material advantage until after the second operation. In case 6 it is possible that the iritis was more severe and more prolonged than it would have been had the cataract been mature, although this is not certain. In case 2 and in case 4, the healing was as prompt and the restoration of vision as complete as could be expected after the removal of mature cataracts, and no secondary operation was required.

But, on the other hand, if operation had not been done on the immature cataract, these patients were doomed to years of disability from loss of all useful vision. In cases 2 and 4, it is altogether probable that waiting for the maturity of the cataract would simply have meant leaving the patients to end their days in blindness. If the good accomplished by it ever justifies a cataract operation, it justifies the operation in such cases.

Ripening Operations.—This one question can be raised about immature cataracts. Is it better to extract the unripe cataract, or to do some preliminary ripening operation? My experience with ripening operations has, without exception, been

favorable. (Transaction American Ophthalmological Society, 1893). But even if this were the universal experience, which it is not, I think it very doubtful if the ripening operation would be worth doing in any considerable class of cases.

The chances of a subsequent secondary operation being necessary, or at least beneficial, are not materially diminished by the preliminary ripening; and the slight gain in ease of extraction and brilliancy of immediate result, scarcely compensates for the additional period of waiting after the preliminary operation, before the chief operation can be done. This view with regard to operations for ripening is substantially the one held by Knapp, Weeks, de Schweinitz and others, who have expressed themselves on this point in recent years. The latest writer on the subject, W. S. Dennett, dismisses the question of ripening operations by merely remarking: "They are not worth while." (New York Eye and Ear Infirmary Reports, 1901.) That ripening operations are better than waiting for spontaneous maturity of cataract in many cases, there can be no question. But now that we have learned that immature cataracts can be extracted with safety, their field of usefulness has largely disappeared.

Cataract Confined to One Eye.—Of course, what has been said about the advantages of extraction of immature cataracts applies only when vision has been greatly impaired or lost in the other eye. If in the other eye, vision is normal or as good as the cataract extraction is likely to give, there is little reason for doing extraction before the cataract reaches maturity.

When one eye presents a mature cataract, should it be extracted even if the other has normal vision? This question was raised in cases 3 and 7. Under some circumstances it may be proper not to advise any operation. Patients who are old and feeble, and who do not lead an active life, will experience but little benefit from the removal of the cataract. But those who are younger and who lead an active life should always be advised to have a ripe cataract removed.

As a rule, the removal of monocular senile cataract will not restore true binocular vision. The strong lens required by the aphakic eye prevents it from working satisfactorily with the eye which retains its crystalline lens. The chief positive gain from the extraction in these cases is from the increased field of vision. Even without any cataract glass, the patient will gain by the operation the full binocular field for all practical purposes. In this way he will be saved from the dangers of accident that attend one who is blind of one eye. The extent of this advantage will of course depend upon the patient's activity and liability of exposure to such accidents.

The other gains through the removal of the cataract in such cases are the avoidance of the risks of hypermature cataract, and of temporary blindness should the other eye become involved. The danger of a cataract becoming hypermature is much less in an old person, while in one under 50 there is every probability of such an event. The risks from hypermature cataract are quite serious. I have recently seen an eye very badly damaged by glaucoma, apparently due to this cause. H. Gifford, in

discussing the dangers of the spontaneous cure of senile cataract, reports four cases of the kind. (American Journal of Ophthalmology, October, 1900), and H. D. Bruns (American Journal of Ophthalmology, February, 1901), reports an additional case.

I have seen the good eye largely disabled from the irritation caused by the movements of the iris over the hard rough anterior surface of a partly calcareous lens in the other eye, the removal of which gave immediate complete relief. The extraction of a hypermature cataract is attended with decidedly greater danger than is the removal of one that is simply mature, or even immature. I should always regard an overripe cataract as one that was seriously complicated. As a rule, the capsule becomes thickened, increasing the difficulty of extraction, and rendering a secondary operation necessary and more difficult. Then a hypermature cataract in a relatively young person is generally quite white, making a very noticeable deformity. Several times I have extracted such cataracts from completely blind eyes, simply because of this cosmetic indication.

One cannot urge operation for monocular cataract just as he would urge iridectomy for acute glaucoma; or enucleation of a blind eye that threatened sympathetic ophthalmia. But he can lay these important considerations before the patient, and positively advise extraction in most cases before the age of 60, and in some at a still later age.

Simple Extraction.—In the above cases simple extraction was done except in case 1. But it may be questioned if case 6 was not also better suited to extraction with iridectomy. I will not here discuss the advantages of simple extraction in cases suited for it. They are well illustrated by the patient shown. In the after-treatment, the especial danger of this operation is prolapse of the iris. This danger is lessened by the use of eserine. In the one case in which prolapse occurred eserine was not used, and the long time the wound remained open with the habit of nipping the lids together invited such an accident.

The Dressing.—The simple dressing employed in all the cases is one that I have used for 15 years after cataract extraction. Besides its simplicity, it seems to me to better meet the indications than any other. It consists of a small loose mass of absorbent cotton held in place by one or more strips of adhesive plaster, extending from the brow of the cheek. It is applicable to many other conditions requiring some sort of ocular dressing. I have never seen any bandage that would retain a dressing with the accuracy, with as little chance of displacement or disturbance by turning the head on the pillow.

When used after cataract extraction, the dressing must be removed with especial care, not to provoke a squeezing together of the lids by the pull of the plaster. During the first few days I usually cut the plaster, leaving the part in contact with the skin undisturbed. After the first dressing, the new strip is attached to the piece left fast to the skin.

I have never used any form of protective mask after cataract extraction, to prevent the patient from striking the dressings and reopening the

wound. But, in over 200 cases, I have never had any serious interference with healing from this cause. Those who use such masks have occasionally reported that the accident which it was sought to guard against occurred when the mask had been removed. It seems rather an insufficient precaution, and yet, impressing the patient strongly at the time of operation, with the idea that the hands must be kept away from the operated eye—establishing the habit of inhibiting movements in that direction—seems to have proved quite as reliable and effective in preventing such accidents as any mechanical device. When the mask is relied upon this habit of keeping the hands from the eyes is not acquired, and then when the mask is left off, the accident occurs.

Delayed Union.—These cases illustrate the variety in the length of time required for closure of the corneal incision. In case 7, the anterior chamber was found of full depth at the end of 30 hours. In case 2 it was not so completely re-established until after 15 days. Yet in both cases the result was favorable, although in case 2 the prolapse was probably due to this long delay in closure of the wound. I have once had the incision remain open for 21 days. This case also did well in every other respect. These cases of slow healing have usually been marked by rather deficient hyperemia of the eyeball for several days after operation. Case 2 of this series was no exception. The closure of the wound has several times appeared to be hastened, as in this case, by removing all dressings and allowing greater freedom of movement.

Risk of Expulsive Hemorrhage.—Case 5 was one that was undertaken with especial anxiety. Expulsive intraocular hemorrhage, following lens extraction, is a rare but utterly disastrous accident. I have twice encountered such hemorrhage, once following removal of the lens in absolute glaucoma, hoping to escape the necessity for enucleation, and once after removal of a dislocated lens. In this latter case I had not left the hospital when the hemorrhage occurred. Placing the patient in the upright position, the free flow of blood from the eye was immediately stopped. Since then, I have operated three times for cataract extraction, in patients that seemed to be in especial danger of such hemorrhage, with the patient sitting up; and have kept her sitting up for several hours afterward. In none of these cases did hemorrhage occur. In this patient, therefore, in whom the previous cerebral hemorrhage, the marked vascular disease, and her stout, heavy build, all indicated especial danger of intraocular hemorrhage, the operation was done with the patient sitting in her chair; and she was kept with her head high until after the corneal wound had closed.

Secondary Operations.—Secondary operations were done in but three of the seven cases. This unusually small proportion was due to special causes. In case 3, the patient has perfect vision in his other eye, and does not need to wear correcting lenses. He sees just as well with the eye as it is, as he would after a secondary operation, even though that should give him perfect vision with a correcting lens. He probably has many years of life before him. It is not certain that after opening the pos-

terior capsule and hyaloid membrane, the nutrition and health of the eye would be as well preserved for a period of many years. If a secondary operation should ever be of advantage to him, it can then be done. Until that time the eye is better as it is.

In case 7, the escape of vitreous occurred through a large central opening in the capsule, so that we had the effect sought by a secondary operation without having to do one. In cases 2 and 5, sufficiently good vision was obtained from the primary operation. In case 2, it might be improved by making an opening in the capsule, but the patient was satisfied with the vision he had (4-8); and extremely anxious not to be detained away from home. It is possible that in these two cases, a thickening and wrinkling of the capsule may occur in the next year or two, that will make its division desirable. This very often happens, and in any large series of extractions fully three-fourths of the cases will ultimately be the better for a secondary operation.

Results.—According to the usual standards, in six of these cases, the result is to be counted a perfect success, (vision ranged from 4-4 to 4-10. In the seventh it was a partial success, 10-200. It has been customary to count as perfect successes all cases obtaining vision of 20-200 or 1-10. But this standard is too low. Even Schweigger's proposition to raise the standard for perfect success to 1-6 is scarcely sufficient. Probably to make 20-100 the requirement for perfect success would be better. With most patients 1-5 vision allows of reading ordinary type, writing, sewing and all ordinary occupations that do not require especially acute vision. If the vision falls much below this, the patient is prevented from freely doing these things.

But these standards of success, perfect or partial, are of little practical importance as regards the individual case. The general rule must be, to aim at the best vision possible. If a patient with vision of 20-40 can be brought up to 20-30, or even 20-20 by a secondary operation, it is worth doing. Then the vision obtained furnishes but a poor criterion of the perfection of the operation. In the great majority of cases, that fail to reach perfect vision, the impairment is due to defects of the eye apart from cataract, that existed before the cataract was removed. Perfect vision is not the rule in senile eyes that are free from cataract; and when the nutrition of the lens suffers, the nutrition of other parts of the eye is commonly impaired also.

Cataract extraction has been less affected by the evolution of antiseptics than any other important surgical operation. We must disclaim the possibility of making the operation absolutely aseptic. It is done with recourse to few of the more pretentious methods and procedures by which asepsis is supposed to be secured in other capital operations; and yet, is there any other surgical operation that can show a better record, as regards infection. Our experience with it seems to teach the lesson, that the line is yet to be drawn between essentials and non-essentials in the technique of aseptic surgery.

ABSCESS OF THE ORBIT FROM DISEASE OF THE ETHMOID; CURETTING THROUGH THE ORBIT AND DRAINING THROUGH THE NOSE.

BY GEORGE C. HARLAN, M. D.

A rather delicate looking lad, sixteen years of age, was referred from the Nose and Throat Dispensary of the Pennsylvania Hospital to the Eye Department. He had been suffering with nasal catarrh for a year or more, and Dr. McCoy found an extensive oedematous swelling of the mucous membrane of the nose and caries of the middle turbinated bone. The lids were swollen, and there was a high degree of exophthalmos of the right eye, the ball being projected downwards, forwards and outwards and its motions limited. The vision was not much impaired. Indistinct fluctuation could be detected, and the patient was admitted to the Hospital on March 14, and a deep incision just below the upper margin of orbit gave exit to a quantity of pus. Careful probing of the cavity failed to reveal dead bone or any connection with the accessory cavities, and it seemed that the abscess was the result of a secondary focus of inflammation. Twelve days later, however, while introducing a gauze tent, dead bone was felt and a probe was then passed through an opening in the wall of the orbit. It was therefore decided to operate at once. An incision was made along the upper margin of the orbit, commencing at the junction of its middle and outer thirds and curving down the side of the nose to the level of the tendo-oculi. The periosteum was then stripped from the median wall and half of the roof of the orbit, and the soft parts, including the eyeball, were drawn outwards with a retractor. A patch of necrosis in the os planum and an opening into the posterior ethmoidal cells were found. When the dead bone was removed with the cutting forceps the opening admitted the end of the index finger. The frontal sinus and anterior ethmoidal cells did not appear to be involved. The ethmoid cells were curetted with a sharp spoon. A rubber drainage tube was then introduced into the orbit through the nose, by means of a retractor silver probe very sharply curved, and held in position by a silver wire passed through sound skin at the root of the nose and fastened to the forehead by rubber plaster. The upper end of the tube was thus just behind the skin, while the lower projected from the nostril. The wound was closely sutured, and the abscess cavity was syringed twice a day through the tube, at first with boric acid solution and after a few days with peroxide of hydrogen, one part to two of warm water. There was very little reaction and the wound healed promptly, except where the abscess had been opened where there is still a fistula which is daily diminishing in size. The exophthalmos is rapidly subsiding and the eye now moves freely in all directions.

This is practically the Jansen operation for empyema of the frontal and ethmoidal sinuses, except that instead of packing the cavity with gauze, as Jansen does, drainage through the nostril is used and the wound is sutured. At the last meeting of the American Ophthalmological Society I reported two cases—one of the empyema of the anterior ethmoid cells and one of empyema of the frontal sinus and of all of the ethmoid cells operated upon with this same incision. A permanent cure resulted in each case with a scarcely visible scar; the cicatrix being practically concealed by the eyebrow. I hope for a quicker result in this case, as in the others I allowed the tube to project from the wound, as well as from the nose, for a month and so retarded the healing. This does not seem necessary, as the wire holds the upper end of the tube just behind the incision of the skin, making thorough cleansing easy, while passing as it does through the sound skin, it does not interfere with the healing of the external wound. The healing would probably have been more prompt if I had performed the radical operation at once instead of establishing a fistula by

lancing the abscess and allowing it to drain through the puncture for twelve days. It, however, seems likely to close in a short time. A primary abscess of the orbit, except from traumatism, is very rare. These abscesses are nearly always connected with diseased bone, generally with empyema of the accessory cavities, and when the nose is known to be diseased, simple evacuation of the pus is much the same kind of surgery as is making a Wilde incision, instead of performing the radical operation, in case of abscess of the mastoid.

PURULENT CHOROIDITIS, FOLLOWING AN ATTACK OF MUMPS; DIAGNOSIS, METASTATIC CHOROIDITIS, REVISED BY STUDY OF THE ENUCLEATED EYE-BALL.

BY JOHN T. CARPENTER, M. D.,

of Philadelphia.

Deep-seated, purulent inflammation of the eye having its origin in the choroid or retina, may be the result of infection from without; as, for example, from penetrating wounds by foreign bodies, from operations or from ulcers of the cornea. On the other hand, the infection may originate within the body and cause choroiditis or retinitis by metastasis.

Metastatic choroiditis following the infectious fevers of childhood is not of very frequent occurrence, but we find cases in literature which have followed pneumonia, typhus, variola, measles, scarlet fever and other infectious diseases in which the development of the purulent choroiditis is explained in a rather vague way as due to changes in the vascular or lymphatic system.

The explanation of foci of suppuration in the choroid associated with ulcerative endocarditis, suppurative diseases of the sinuses adjacent to the orbit thrombosis of the orbital veins or with general septicemia is much less difficult. That most of these cases are due to the lodgement of infected emboli is no doubt true. Germann, *St. Petersburg Med. Woch.*, Dec. 15th, 1900, found during convalescence from pneumonia a purulent metastatic irido-choroiditis with symptoms of meningitis and death in six days. Another fatal case is described in which croupous pneumonia was followed by endocarditis, embolic retinitis and panophthalmitis. Pure cultures of the diplococcus were derived from the anterior chamber.

In 1892 Herrnheiser observed metastatic panophthalmitis with diplococci in the choroid, consecutive to croupous pneumonia. Blessig, Everbusch and Natanson have each reported metastatic irido-choroiditis after influenza.

Cases studied from bacteriologic standpoint have not yet been very numerous, but as our knowledge of the specific germ of the infectious fevers increases, no doubt these will be more frequently found.

Schiess (quoted by Kniess—"Eye in General Diseases") observed metastatic irido-choroiditis which necessitated enucleation following an attack of mumps.

The following notes of a case of deep suppurative inflammation of the left eye in a young child just

recovering from mumps, in which the diagnosis of metastatic choroiditis was made, contain some points of interest which seemed to me sufficiently striking to merit the report of the clinical history.

Harold, aet 2, of Carlisle, Penna., was brought to me on July 13th, 1896, by Dr. S. S. Bishop.

Previous history: Four weeks ago he had a severe attack of mumps which was worse on the left side. About two weeks after recovery his parents noticed the left eye was inflamed, and that the child was restless and evidently suffered pain in that eye. One week later Dr. Bishop found the following conditions present: lids were swollen; conjunctiva chemotic, with engorgement of both superficial and deep vessels; the cornea steamy; the iris bound down by unyielding synechiae; and a deep-seated yellowish reflex behind the pupil. The entire uveal tract became involved and a large hypopyon developed; no evidence of light perception in the eye.

Conditio praesens: There is deep ciliary injection; the cornea opaque and steamy, and quite insensitive; anterior chamber obliterated; pus is seen blocking the iris, which is degenerated and atrophic. As its upper periphery there is localized bulging of the iris, which is completely atrophied and looks as if upward iridectomy had been made. Commencing staphyloma was noted in upper ciliary region; eyeball stony hard. No evidence of penetrating wound was found.

In view of the history of the case and the early existence of purulent infiltration of the vitreous without any evidence of external injury, the diagnosis made was, metastatic choroiditis following mumps. Because of the severe pain from which the child was suffering, together with the increased tension of the eyeball, and the probability of early rupture of the sclera as shown by its staphylomatous condition, enucleation was advised and performed and the eye placed in Dr. Edward A. Shumway's hands for study.

After hardening in alcohol, the eyeball was frozen and cut in half in a horizontal plane passing through the cornea and optic nerve. It was found to be filled with a brittle white mass, in which the lens was embedded. The upper half was mounted in glycerine-jelly, and the lower half embedded in celloidin for microscopic sections. On cutting the lower part of the celloidin block, in order to mount it squarely on the object holder of the microtome, the knife struck a small particle of rusted metal, lying in the retina, which measured (1x1.5mm.) This was dissolved in strong hydrochloric acid, and on the addition of potassium ferrocyanide, a dark blue color was produced (Prussian blue), indicating the presence of iron.

Microscopic examination of the sections, stained with haematoxylin-eosin, showed the condition to be beginning panophthalmitis.

The cornea is intact, except for a moderate infiltration with round cells, and distension of the blood vessels, at the limbus. In the center, Descemet's membrane is torn, but this is probably an artefact. On the nasal side, in the ciliary region there is a depression in the globe, the iris is here adherent to the corneal surface which is especially infiltrated with round cells at this point. The anterior chamber is filled with a granular material which contains a few leucocytes. The iris is swollen to several times its normal size, and densely infiltrated with polymorphonuclear leucocytes, which have separated widely its stroma-cells.

Its anterior surface is covered with a layer of fibrinous exudate, with a few entangled leukocytes, which extend from its posterior surface, in a thin layer, over the entire surface of the retina, and in two lines converge from the equator of the lens on either side, toward the optic nerve entrance.

The remainder of the vitreous cavity is filled with a granular exudate, which contains scattered pus cells. The anterior capsule of the lens is ruptured on the temporal side, and a line of pus cells runs directly backward through the broken and cataractous lens fibres, to communicate through a similar rupture in the posterior capsule, with the masses of cells in the vitreous, showing the apparent track of the foreign body. Lines of pus cells also follow the lines of cleavage of the lens fibres, and on the nasal side, at the equator, a large collection of them separates the capsule from the cortex. The ciliary processes are drawn forward, and the ciliary bodies are mod-

erately infiltrated. The layer of pus cells on the inner surface of the retina, is much thicker on the temporal than on the nasal side, and at a point just posterior to the equator shows a break in the mass. The sections are stained a brownish red, in this position and on treatment by the Perl iron reaction (Hydrochloric acid and Potas-ferrocyanide) take a deep blue color, which gradually fades in intensity, as the distance from this point increases.

The underlying retina shows a dense infiltration with round cells, especially surrounding and filling the blood vessels, but the process has not lasted long enough to completely disorganize this membrane, as its various layers may be readily distinguished.

The pigment cells are proliferated, and are commencing to infiltrate the retina. The distant parts of the latter show edema and infiltration with cells around and in the blood vessels.

The choroid is hyperemic and at the point above described corresponding probably to the former position of the foreign body before it fell to the bottom of the vitreous cavity, it is thickened to three times its normal size, and is densely infiltrated with round cells.

The optic nerve is moderately infiltrated. A careful search for micro-organisms was made, but none was found.

Diagnosis. Beginning panophthalmitis; traumatic cataract, foreign body (iron particle) in the vitreous.

In order to explain if possible the presence of the foreign body in the eye, careful inquiries were made with the following result. A blacksmith's shop was situated just back of the house in which the child lived, and during his convalescence from mumps he had been allowed to play most of the day in the shop. No doubt the small chip of iron from the anvil penetrated his eye, although no one's attention had been called to such an accident. The development of purulent choroiditis from this foreign particle led to acute inflammatory symptoms which the child's mother detected, and for which he was brought for treatment.

It is impossible to say how soon after the entrance of the chip of iron into the eye the examination was made, but no trace of the wound was discovered by Dr. Bishop, and one week later when the eye-ball had become generally infiltrated with leukocytes there was certainly no trace of the track taken by the foreign body.

In the absence of any history of traumatism, an attack of purulent choroiditis in a young child who was convalescing from mumps was naturally interpreted as metastatic choroiditis. The accidental discovery of the foreign body, in making repeated sections with the microtome, alone enabled us to correctly interpret the nature of the attack. It was most fortunate, in the light of this discovery, that enucleation was promptly done and sympathetic ophthalmitis in the sound eye was prevented.

SPONTANEOUS (?) RUPTURE OF THE SPLEEN. LAPAROTOMY—DEATH—REPORT OF CASE.

By D. C. HOWARD, M. D., Captain, Med. Dept., U. S. A.

G. C., 22 years of age, a private of Battery "O," 4th U. S. Artillery, single, birthplace, U. S., 2½ years in service. Served at this post for past eight months. Used alcoholics immoderately at times. He was brought to hospital 10 A. M., February 19th, in a state of practical collapse. Complained of agonizing pain in abdomen, especially in left hypochondrium and stated that he had not felt well for several days previously. Denied any injury to abdomen. Had not been drinking for two weeks. Had eaten but little food for several days, bowels constipated. A comrade occupying an adjacent bed in barracks stated that the patient had complained of a cramp-like pain in left side for a week past, that in walking his body was bent forward to relieve

the pain. At night he was restless and coughed considerably. On the morning of February 17 he was seen to be very pale and advised to go to the hospital. However, he did full duty with his battery until the morning of admission, when at about 9 A. M. pain became very intense, vomiting set in and he suddenly became very weak.

On admission he was exsanguinous in appearance; pulse small, rapid and weak, respirations frequent and shallow, temperature 99.4, extremities cold. He called constantly for water and drank eagerly the large quantity brought him from time to time without allaying the intense thirst. He was in paroxysms of pain located chiefly in left hypochondrium. External warmth applied and morph. sulph. .030 gm. with atropine given at once. In a short time he became more comfortable, and a careful abdominal examination was made. Abdomen was rather prominent and tense and extreme tenderness noted, but more marked in left hypochondriac and left half of epigastric regions. Complete dullness in left hypochondriac and left lumbar regions, extending to the right as far as the left border of rectus in epigastric and umbilical regions. Upper limit of dullness was at a point 1½ inches below nipple line. Below, it extended to crest of ilium. No thoracic abnormality noted. Urine, 100Cc. removed by catheter, examined with negative result. The appearance of the patient was so suggestive that a dangerous intraperitoneal hemorrhage was recognized, though its source was undetermined. With no history of previous disease nor abdominal injury to suggest splenic rupture the condition was considered more likely to be pancreatic hemorrhage. Though his condition remained critical, his pulse and respiration had improved somewhat, and, after consultation with Acting Assistant Surgeon E. H. Porter, U. S. Army, as to the advisability of immediate operation, it was decided to await further developments. He dropped into a quiet sleep about 1 P. M. An hour later he awoke, and during a momentary absence of the nurse from his bedside arose and went to the water closet, where the nurse found him a moment later on the closet seat in collapse. He was carried to his bed and I saw him at once.

He was pulseless, respiration 50 per minute, shallow and frequently sighing. Extremities cold and covered with clammy perspiration. Abdomen showed marked increase in limits of dullness. Hypodermics of ether and brandy given at once and frequently repeated. Hot saline solution, one liter given per rectum. External warmth and friction to limbs employed. After a few minutes a pulse could be felt, rapid and weak (140 per minute). Violent paroxysmal pain now complained of. Acting Assistant Surgeon E. H. Porter now saw the man with me and coincided in my opinion that an immediate operation gave him his only chance, though it was hardly believed that he could survive it. Preparations for operation were at once begun, though one and one-half hours elapsed before they were completed. Meanwhile, under free stimulation and subcutaneous injection of 500Cc. normal saline solution his pulse had improved (120 per minute), his extremities had become warm, and general improvement noted. Temperature, 99.4.

Exploratory Laparotomy, 3.30 P. M.

Eucaine solution (4%) used for infiltrating tissues in line of incision. A few whiffs of ether were given from time to time, but never to point of anesthesia. Assisted by Acting Assistant Surgeon E. H. Porter and hospital corps attendants, an incision four inches in length was made in left semi-lunar line about one inch below free border of ribs, which was rapidly carried down through the muscular planes to peritoneum. Great tension within peritoneal cavity was indicated by marked bulging through incision when the peritoneum was reached. The peritoneum was carefully nicked when a column of blood serum mixed with blood spurted upward with great force to a height of several feet. The opening was enlarged the length of incision, and an enormous amount of fluid poured out, which it is impossible to correctly estimate, but it is believed the amount was at least two liters. Strychnine and brandy hypodermically had been freely given during operation, but the sudden escape of so much fluid from the peritoneal cavity nearly collapsed patient, and heroic stimulation was again demanded. Hypodermoclysis again employed. Rapid exploration was now made, and spleen was found adherent to diaphragm, greatly distended with blood clot, and firmly attached to its concavity was a mass of blood clot filling the lesser peritoneal cavity, its surface as smooth and firm as the

splenic capsule itself and as large as an infant's head. In the patient's critical condition further operative interference would certainly have ended his life on the table. It was seen that nothwithstanding short of total extirpation of spleen and removal of haematoma would be of lasting benefit, and that the patient's condition would not allow. The peritoneal cavity was therefore filled with hot saline solution, gauze strips packed deeply in concavity of spleen, upper angle of wound hastily closed by suture and a thick gauze dressing applied. He was removed to warm bed, freely stimulated, salt solution given and very slowly reaction set in. The operation, by relieving tension, had relieved all pain. Temperature 98, pulse 130, extremely weak. Throughout the evening and night he was in a calm sleep most of the time, but would rouse when spoken to. Took water and stimulants by stomach, though hypodermic stimulation was continued. Pulse ranging from 120 to 160. Temperature, 2 A. M., 99.6. Death occurred at 6.45 A. M. February 20, over fourteen hours following operation.

Autopsy, 4 hours after death.

Body of muscular man, 5 feet 10 inches in height, weighing about 165 pounds. No rigor mortis. Gauze dressings of operative wound saturated with bloody serum. Abdomen opened from ensiform cartilage to pubes. Overlying stomach, intestines and liver there was a thin layer of clotted blood, soft and friable. Nearly 600Cc. bloody serum in greater cavity of peritoneum. The spleen was firmly adherent to diaphragm. Capsule distended with blood clot, with a rupture 12 cm. in length leading from hilum downward along its inferior surface, then upward to centre of convexity. The margins of ruptured capsule were separated 8 cm. midway from angles. From this point protruded a globular mass of clot into the lesser peritoneum continuous with that distending the ruptured spleen. From examination by touch it was almost impossible to define the limits of the spleen and that of the attached clot, as both were of equally firm consistency. In removing the organ the blood clot was accidentally detached just beyond the splenic border. It was practically encapsulated by the lesser peritoneum. Weight of detached clot .960 kilogram. A portion of omentum about 10 cmx10 cm. was removed with spleen as it served as a portion of haematoma capsule and was densely infiltrated. Weight of spleen and contained clot with omentum as above, 1.1 kilograms. Left lung collapsed, 500Cc. bloody serum in left pleural cavity. Small perforation in diaphragm, posterior segment well to the left. Pericardium contained 16Cc. straw colored serum.

In the photograph, "A" can be seen the widely separated margins of splenic capsule and the central blood clot with infiltrated omentum. Exposure on day of removal. The specimen has been preserved and sent to the Army Medical Museum, Washington, D. C.

Remarks.—Splenic rupture with fatal intraperitoneal hemorrhage most often follows traumatism, but it also is said to occur spontaneously in acute enlargements of the organ during typhoid and malarial fevers in certain localities. According to Osler the condition is very rare in this country. In the case reported an element of doubt must remain as to its cause. It is assumed, however, that the rupture occurred spontaneously in the absence of history to the contrary. As to traumatism, it is possible that while intoxicated at some time he may have sustained an injury to splenic region, of which he subsequently remembered nothing. No marks of injury to body, either recent or remote, were found.

Acute enlargement from malarial infection cannot be positively excluded as a predisposing cause of rupture, malarial diseases being prevalent here at all seasons. It is not probable, however, as a malarial infection of sufficient intensity to cause such enlargement would most likely have come to the notice of the Medical Officer. This man had been under treatment for slight injuries only during his service here. As to typhoid, there has been but one case in this command for 18 months past, that case

being imported. It is considered a more improbable cause than others mentioned.

Undoubtedly some splenic disorder existed several days before rupture. Whether it was simple congestion or an acute splenitis, both from causes unknown, must remain unanswered.

EPHEMERAL INSANITY WITH REPORT OF TWO CASES.

By CHARLES J. ALDRICH, M. D.,

of Cleveland, Ohio.

Lecturer on Clinical Neurology and Anatomy of the Nervous System, Cleveland College of Podiatric Medicine and Surgery; Visiting Physician and Neurologist to the Cleveland General Hospital and Dispensary; Neurologist to the Cleveland City Hospital.

The occurrence of insanity which has a duration of a few hours or a few days in an otherwise apparently healthy and normal individual possesses not only great medical interest, but involves questions of forensic medicine that are tremendous in significance and scope. Clouston has described this form of insanity as "*mania transitoria*," but since the word transient means passing, without any particular reference to time, it has occurred to the writer that the other term used by Clouston—ephemeral insanity—is the better one.

Clouston believes that most of these cases are epileptiform—the mental epilepsy of Hughlings-Jackson, or the masked epilepsy, the "*épilepsie larvée*" of Morel; that a few cases are seen in young persons of unstable nervous and mental organization, and usually possessing an intense neurotic heredity. None of these causes or predispositions will explain the advent of insanity in my cases.

It seems very strange that any person who has never suffered an attack of mental aberration or epilepsy should suddenly become insane and remain so but a few hours or a few days and then recover without one bit of demonstrable mental peculiarity remaining.

The following cases serve to illustrate this phase of insanity, and are very suggestive as to the legal complications which might arise.

CASE I. L. G., age 18, female, white, German, domestic, with good family history; has been uniformly healthy and never suffered from any sickness but those incident to childhood; no history whatever of any unconscious spells, spasms or evidence of mental aberration. She was employed in the family of Mrs. R., who looked upon her as a very trustworthy, honest and religious woman. She has never indulged in narcotics or stimulants of any kind. She retired at an early hour on the night preceding the Fourth of July, 1898, intending to arise in the morning and view a street pageant. In the morning about four o'clock her mistress was aroused by her pounding upon the door and loudly calling for her to come out. Mrs. R., opened the door and found the young woman standing in her night clothes with a Bible under her arm. When the door was opened she threw her arms around her mistress and begged her to come with her. Her mistress, thinking that perhaps the house was on fire, urged her to tell what was the matter. She answered that the world was about to end and Christ had sent her to save her mistress. This insane talk appraised Mrs. R. that the girl was in delirium, and she immediately began to soothe her, telling her to go and dress. The girl retired to her room, put on her best clothing and came downstairs, ate a hearty breakfast which her mistress had prepared for her, talking in the meantime incoherently on religion and the threatened destruction of the world. Soon after this a young woman friend appeared who was to accompany her to witness the street pageant and persuaded her to go and view the procession. Carefully and neatly

dressing herself, and taking her Bible under her arm she walked half a mile and stood nearly one hour watching the procession, most of the time in perfect silence. Then she declared herself to be very tired and wished to return to her place of employment. Upon arriving at this place she immediately undressed herself, put on her night-clothing, folded up the garments that she had worn, and put them away in her usual manner. She then retired and immediately fell asleep. She slept for a period of about five hours and awoke with a dim recollection only of the street pageant. She has since been under observation for a period of two years and has never manifested the slightest degree of mental aberration. She has no sonnambulistic tendencies or symptoms that would lead to the idea that she is mentally unbalanced or suffering from masked epilepsy.

The following case I had the pleasure of seeing with Dr. Friedman at the Cleveland General Hospital:

CASE II. R. L., Hungarian, age 40, married, paver. He gave a good family history: had previously enjoyed good health and no mental aberration had ever manifested itself.

One day while at work and without having complained of any ailment, he went to his foreman and told him that two of his fellow-workmen were plotting to kill him and that one of them had a knife concealed in his clothing with which he intended to assault him. He declared that he had heard them talking and planning his destruction, and begged the foreman to prevent its accomplishment. The man seemed so sincere and had always been such a sober, industrious, peaceful workman that the foreman believed his story and called the other men to account, who, it is needless to state, were perfectly astounded. There had never been one word said in reference to the complainant and on search, neither of the men was found to have anything that might have been mistaken for a weapon. He insisted, however, with added vehemence that he had heard them plotting and planning to kill him and had seen the knife. He was taken to his home and thence to the Cleveland General Hospital. He had no fever nor bodily ailments whatever, neither could the slightest history of any spasmodic seizures or mental aberration previous to this time be obtained from his family or friends. He was kept in bed for a few days and treated symptomatically. Shortly he discovered that he had been a victim of delusions and seemed surprised that they had occurred but was unable to assign any cause. He was discharged from the hospital in a few days, since which time I have heard that he has been in perfect health and has never had a recurrence of his delusions or other evidence of insanity or epilepsy.

Fatty Degeneration of the myocardium considered as a Fatty Infiltration on the Cardiac Fibers. LOUIS GALLAVARDIN. (*Gaz. Heb. de Med. et de Chém.*, March 24, 1901, 48 me. Annee No. 24. Lyons Thesis, 1899-1900, No. 155).

Fatty degeneration of the myocardium may present 2 different anatomical varieties; (1) That in which the fatty change in the cardiac fibers occurs in the form of islands, principally beneath the endocardium, and (2) That in which the fatty change in the cardiac fiber is diffuse. When the fatty degeneration exists in islands the grouping of these islands beneath the endocardium and their whitish appearance produces a characteristic marking known as subendocardial mottling. This sign is pathognomic of this form of fatty degeneration of the myocardium. By the use of injections of coloring matter the general disposition of these islands of fatty degeneration is seen to be controlled by the vascular distribution, and in the majority of cases they seem to be situated in the portions of the myocardium that are injected with greatest difficulty. The cells that compose these islands are cardiac fibers regularly infiltrated by fine fatty granulations, but presenting neither the characteristics of necrobiosis nor of cellular degeneration. The diffuse form of fatty change in the myocardium is only to be diagnosed after microscopic examination. Fatty degeneration of the myocardium is rarely found in the course of the acute infections. It follows frequently, on the other hand, in the course of cardiac affections or of chronic pulmonary diseases accompanied by insufficient oxidation of the blood, and in the course of cachexias and anemias. The sympto-

matic expression of this lesion appears to be restricted. It has little influence upon the course of the affection which it complicates. Gallavardin admits, however, the possibility of sudden death and attacks of cardiac failure in obese patients. The author attributes to this lesion a signification analogous to that of fatty liver. This lesion is, then, according to the views of the author, neither a myocarditis nor a fatty degeneration, but a fatty infiltration of the cardiac muscle fibers. And he proposes to employ the term **fatty myocardium** or **fatty infiltration of the cardiac fibers** for it. [J. M. S.]

Prostatic Abscess Which Opened into Both Urethra and Rectum.—In the *Annales de la Polyclinique de Bordeaux* for March, 1901, Dr. E. Loumeau reports the case of a man of 35, in whom gonorrhea or gleet was constant. For two weeks before consulting his physician, his symptoms had become aggravated. Though examination showed no sign of recent gonorrhea, permanganate injections were given. At the moment the liquid reached the bladder, the patient experienced sudden severe pain in the perineum, followed by a chill and a temperature of 104° F. This perineal pain persisted with frequent urination, a few drops of blood appearing at the end of micturition. Pus was found in the urine in large quantity. The diagnosis of acute prostatitis with cystitis was made. Complete retention of urine occurred, to relieve which catheterization was employed, though so painful that chloroform was necessary. Rectal palpation at this time revealed an abscess in the right lobe of the prostate, which was evacuated through the urethra by pressure with the finger. As this treatment yielded no good result, the abscess, which had pointed in the rectum, was opened there. The cavity was cleaned out, dried with gauze, and drained per rectum. The fever and pain disappeared. **Pneumaturia** was noticed for a few weeks, but no fecal matter was seen in the urine, or urine in the bowel movements. Two weeks after operation, right epididymitis occurred, going on to suppuration. This abscess was also opened and drained. The patient, who had wholly recovered, left for Brazil, where he died of yellow fever six months later. This phlegmonous prostatitis opened into the urethra, causing a cystitis and urethritis; by its pressure into the rectum, it caused great pain, and after evacuation it was still the cause of epididymitis. Loumeau believes that when such an abscess points into the rectum, rectal incision is to be preferred to perineal section. [M. O.]

Soda Compresses in Suppuration. G. E. Vladimiroff (*Medicinskoje Obozrenie*, February, 1901.) fully corroborates the splendid results obtained by a number of Russian physicians from the use of **compresses of soda in diverse suppurative processes**. The use of this drug in such cases was first suggested by Georgiewski who claimed for it the following advantages: 1. It is cheap and readily obtainable; 2. no drainage is required; 3. the patient is much more comfortable; 4. the pain, at times severe, accompanying the change of tampons is altogether avoided; 5. the bad odor and the unsightly appearance of the dressings are absent; 6. recovery is much more rapid. The author employed this treatment in 30 cases. In 6 there were burns of the second and third degree; in 2 a pustular eruption; in 1 a suppurating fistula; in 10 contused and incised wounds; in 6 suppurating lymphatic glands; in 5 ingrown toe-nails. He employed the compresses in the following forms: 1. a layer of gauze saturated with a 2% solution of soda was applied. This was covered with a piece of oil-cloth, cotton and a bandage. The compress was changed 3-4 times in 24 hours. 2. The gauze next to the body was not removed but kept saturated by pouring on it 2-3 times during the 24 hours a 2% solution of soda. 3. Several layers of gauze saturated in the soda solution were placed over the suppurating surface, these were covered by a thick layer of boric acid and camphor salve, then a piece of oil silk, cotton and bandage. Such a compress remained moist for 1-2 days. **The results obtained were exceptionally good.** [A. R.]

The Pennsylvania Hospital.—The story of colonial Philadelphia will always be an important part of the wider history of the nation. The provincial history of this city has special significance, because it was associated not only with the birth of the republic, but also with the inception of more than one movement, and the origin of more than one institution, which were not merely political, but were widely educational and humanitarian. Among these institutions stands pre-eminent the Pennsylvania Hospital. The steady hand of Benjamin Franklin was felt in its early administration, and its history derives an added colonial flavor from association with the name of "Poor Richard." As Mr. John B. Garrett said in his commemoration address last Saturday at the sesquicentennial anniversary of the hospital, the conservatism of the founders has been preserved in their successors; nothing has been ruthlessly destroyed, and the ways of to-day are in accord with the best traditions of every period of its history. With all this the hospital has kept pace with every advance in medical and surgical science; its name is forever associated with one at least of the greatest reforms in psychiatry; its staff has been for a century and a half recruited from the most distinguished teachers and practitioners of medicine and surgery in the oldest medical center in America; and its benefactions have involved the expenditure of millions of dollars. As Mr. Garrett reminded his hearers, the promoters of the Pennsylvania Hospital were far-seeing men. There was nothing provincial about them or about the scheme which aimed to establish in a colonial city a hospital which was as metropolitan at the beginning as it remains to-day. If aught were needed to emphasize this statement, it can be found in the provision made for the reception and treatment of the insane. This department was destined to become, under Rush, a clinic in psychiatry, which is hardly surpassed anywhere in this country at the present time (and hardly equalled, if literary and scientific results are to be the standard). In the original petition drawn up by Franklin, the insane are mentioned first as the objects of wise hospital treatment.

As it stands to-day in its old colonial building, backed by its modern but less imposing structures,

and supplemented by its great estate in West Philadelphia, the Pennsylvania Hospital is one of the most significant institutions on the continent. It represents a colonial movement of wide scope and foresight, which bears fruit in these modern times quite in accord with our most advanced ideals.

Dividing the Responsibility.—Our friends in San Francisco should understand by this time that it is not easy for medical observers here in the East to solve all the mysteries of the plague situation in that city. Now that the Plague Commission has published its report, the local physicians seem inclined to come forth and blame the State authorities for all the trouble. We have received several letters—explanatory and expostulatory—on the subject. One of our correspondents finds fault with us for reflecting on the authorities out there, and in the next paragraph lays the blame for the concealment of the plague on their "wrong-headed Governor, knavishly advised." He tells us that at our distance "it is simply impossible to realize the forces of evil which have been brought into play to try to smother and suppress the truth as to the plague situation here. The selfish and provincial point of view assumed by the business portion of the community, ably seconded by the San Francisco press, has been responsible for this condition." The power of the State Legislature, he tells us, "has been used to make it a crime to even publish mention of the existence of a plague case."

This is worse than anything we have ever said in these columns about the authorities in San Francisco, and coming from a correspondent whose object is to chide us for being unjust to them, it sounds at least rather odd. If the local authorities in San Francisco, such as the Mayor, City Councils, and Board of Health, allowed themselves to be controlled by a "wrong-headed Governor, knavishly advised," they cannot well evade their responsibility. If they bowed before an ignorant public sentiment and a mendacious press, they did not do their duty. It is not for us to attempt to distribute the responsibility in due proportion among the State and local authorities. In common with the rest of the world we know merely that the whole truth did not come

out until it was brought out by a United States Government commission. The importance of the subject is not confined to the city of San Francisco. It is not a local, but a national affair.

Another correspondent tells us that "The local health authorities had the situation scientifically well in hand, and the rest of the country was never assured by or upon the authority of the Board of Health that there was no plague in the city." To which we can only say that it would have been a source of satisfaction to the "rest of the country" to have known this sooner. We are glad to chronicle the fact that "the cases which had occurred prior to the coming of the Commission had been studied by the local pathologists and bacteriologists in the same manner and with the same thoroughgoing, honest and scientific methods which the members of the Commission employed." This is greatly to the credit of the local health authorities, and they should have full credit for it. The statement, however, only increases our wonderment how, in spite of this fact, it was constantly proclaimed that there was no plague in San Francisco, or, if any, that it was of a "non-contagious" character. We are satisfied that the local pathologists and bacteriologists could not have been responsible for these false statements.

Febrile Albuminuria.—Gerhardt (*Deutsches Archiv. f. Klin. Med.*, V. 1868, page 212) described a condition of the urine occurring in the acute infectious fevers, in which albumin, usually in small amounts, appeared. To this condition he gave the name "febrile albuminuria." The urine in this condition also occasionally contains hyaline tube casts and propepton. It was supposed that this albuminuria was due to the febrile process, and albumin occurring as a result of renal disease, was termed "true albuminuria." Within recent years, v. Kahlden (*Die Aetiologie u. Genese der Acuten Nephritis*, vol. II, page 441) has had an opportunity of examining these so-called cases of "febrile albuminuria" pathologically. He found that in some of these cases almost exclusively the epithelium of the convoluted urinary tubules and Henle's loops was pathologically altered, and in those cases in which the glomerular epithelium was affected, these changes were always secondary. A histological examination of the renal tissue showed that blood was rarely present in the interstitial structure, but almost invariably in the glomerular capsules, and in the urinary tubules. Besides, these hemorrhages were very frequently missed by v. Kahlden in his examinations. He is of the opinion that in the case of "febrile albuminuria" there is actual change in the renal structure, which is identical with the preliminary stages of an acute nephritis, and that the same etiology was respon-

sible for the condition. This etiology depends largely upon toxic substances which circulate in the blood stream. Nevertheless, it will remain justifiable to differentiate between a beginning nephritis and a well developed nephritis, as well in a diagnostic as a prognostic sense. It would be preferable to give to the condition known as "febrile albuminuria," which is, as a rule, transitory, simply the designation "albuminuria," and to leave off the adjective "febrile." The differential points between nephritis and albuminuria would then not be difficult to determine. In the latter condition the albumin is noted during the infectious process. There is, as a rule, but a small quantity of albumin, and hyaline tube casts are occasionally present. In nephritis complicating the infectious diseases, the condition, as a rule, is acute, and albumin and tube casts are present in comparatively large amounts. The term "toxic albuminuria" is not well chosen, as, according to our knowledge, both conditions are due to toxic causes.

The Editorship of "Brain."—We regret to learn that Dr. A. de Watteville has retired from the editorship of this important journal. The announcement is made in the last number of the *Journal of Mental Science* that at the annual meeting of the London Neurological Society, held on February 14th, the resignation of Dr. de Watteville was accepted. The Council of the Society put on record a statement of its appreciation of the way he had conducted the journal for the past twenty years. Dr. de Watteville has brought *Brain* to a high standard of perfection and secured for it a great European reputation. He is even credited with having saved the very life of the journal at a critical period of its existence. The success of his editorial charge, extending over twenty years, deserves wide recognition. *Brain* has come to be an important exponent, not only of English neurology, but to a limited extent of American neurology as well. It has been through its pages that not a few important papers by American neurologists in recent years have been introduced to the still wider field of European specialists. It is to be hoped sincerely that under its new editor, Dr. Percy Smith, it will continue to have a successful career.

The Priority in the Discovery of the Pest Bacillus.—It has been generally believed that the specific microbe of the pest was discovered simultaneously by Kitasato and Yersin, during the Honk-Kong epidemic of 1894. Kitasato's paper appeared July 7, 1894, while that by Yersin was only published July 30. But Dr. Tatsusaburo Yabe, a physician in the Japanese Marine, has shown in the *Archives de Medecine*

cine Navale, quoted by Le Dantec, in the *Journal de Medecine de Bordeaux* (1901, No. 16), that the two bacilli described were not identical. For, while Kitasato made his culture from the blood, Yersin took his from the bubo directly. La Dantec compares the pest to diphtheria; while the Klebs-Löffler bacillus is always found in the membrane, streptococci may appear in the blood. So it seems probable that Kitasato's bacillus was but a microbe of secondary infection. It stained by Gram's method, coagulated milk, made bouillon turbid, and was motile. But Yersin's bacillus, which has been proved the true cause of the pest, does none of these things. Aoyoma has shown that both microbes exist in cases of pest, that of Yersin in the buboes, that of Kitasato in the blood. La Dantec recently received some pest preparations from the Island of Reunion, in all of which Yersin's bacillus existed in pure culture. The bacillus of Kitasato was not found in a single preparation. No doubt, therefore, remains that the bacillus of Yersin can exist alone in cases of pest. This is now generally recognized by bacteriologists all over the world.

Self-Performed Caesarean Section.—Probably nothing better shows the remarkable immunity enjoyed by the peritoneum than the interesting cases of self-performed Cæsarean section, that from time to time are reported in the current literature. Besides manifesting an astounding degree of stoicism, these patients seem to have the happy faculty of evading the disastrous consequences of their temerity, and that notwithstanding the most inauspicious circumstances under which the act is consummated. Filth to them is apparently innocuous, and bacilli have no terrors.

A remarkable fact associated with these blood-curdling reports is that most, if not all, of the cases have occurred among the degraded classes of Southern and Eastern Europe, as in the last instance recorded by Löffler (in the *Wiener Med. Woch.*, No. 10, 1901), the victim being a Turkish peasant woman. Suffering from some obscure chronic affection, and fearing she would perish before the termination of her pregnancy, this stoical creature, at the eighth month of gestation, deliberately opened her abdomen and uterus with an ordinary pen-knife. As the child emerged, the woman fainted from shock and loss of blood. On regaining consciousness some time afterwards the wound was sewed up, at her request, by her thirteen-year-old daughter, an ordinary needle and waxed-hemp thread being employed for the purpose. Notwithstanding these primitive measures, and the fact that a simple Cæsarean section was performed, that is, without the insertion of uterine ligatures, the woman made an uninterrupted recovery. There were no manifestations of

sepsis or peritonitis, and union of the abdominal incision was unattended with suppuration. The abdominal dressing employed was a layer of moss held in place by a filthy linen cloth. The child, which also survived, was nursed by its convalescent mother.

Such cases seem to indicate the uselessness of the modern methods of antiseptics. If patients placed in the most unfavorable of circumstances can recover from the gravest of injuries without the development of any untoward symptoms, it would seem that the extreme care practised by the modern surgeon is altogether unnecessary and a waste of valuable time and material. Such cases naturally fall in line with those remarkable instances recorded of unbroken recovery following most extensive traumatism—accidental, military and surgical.

Many feet of bowel may be resected from one individual without ill-result, while a simple enter-rhaphy in another will be rapidly followed by a fatal termination; gravel, filth, and curious foreign bodies gain entrance into the peritoneal cavity and apparently excite not the slightest irritation, while a simple exploratory incision will be followed by grave or even fatal sepsis. The explanation of this curious phenomenon must be found in some refinement and extreme developmental sensitiveness of the tissues, whereby in one case there will be an apathy of the parts to external influence and in another a high degree of reaction. It is well known that individuals of higher mental and social development will react more promptly to these deleterious influences than will individuals much lower in the mental and social scale. The leader in the community will succumb to a moderately severe peritoneal operation, while the hod-carrier will recover from some grave lesion without any untoward symptom to interrupt the progress of the recovery. In the auto-Cæsarean section, above recorded, and in the others that have filled the curiosity-pages of surgery, this low position in the social scale was one of the attendant features in the cases. It was not because of the lack of surgical care that recovery followed, but in spite of the dangerous concomitants of the operation.

Fallacies in the Chemistry of the Blood.—Although the examination and estimation of the corpuscular constituents of the blood are approaching a stage of perfection, and although the hemoglobin can be estimated to a nicety, much of the chemistry of the blood is still to be discovered. This expansive field of research is fraught with many difficulties. The mineral constituents of the blood have been estimated almost without exception from blood-ash. Unless scrupulous precautions are observed, a portion of the chlorine and the

phosphoric acid is lost. The distribution of acids and bases in the blood taken from the body is different than in the ash; acid salts become neutral or basic, carbon dioxide is produced while the ash is being formed, and may be left behind combined with the bases; furthermore, the carbon dioxide originally present in the form of carbonates, may escape, while the acid phosphates become transformed into neutral ones. Even the iron shows an erroneous picture, because the iron that previously had been combined with albumin may also go over to the phosphoric acid, leaving no clew regarding the distribution of the iron in either organic or inorganic combinations. Another fallacy is that the greater part of the sulphuric acid found is derived from the sulphur in the albumin combinations. Liebig has shown that the amount of sulphur in meat juice is so small that it is almost indeterminable in a whole animal, but, as later investigators have shown, an enormous quantity of sulphuric acid is found in the blood-ash. This is due to the fact that during the formation of the ash some of the organic acids are broken up and the sulphuric acid from the albumin combinations is liberated. The sulphuric acid liberated in this case, although it certainly has nothing to do with the mineral constituents originally present, may, nevertheless, be a marked source of error. Similar fallacies are present in the case of phosphorus, for only a portion of this substance which is found in the ash as phosphoric acid has been originally present as such. The amount of nitrogen is generally somewhat parallel with the amount of albumin, and consequently changes according to the degree of decomposition of the latter. In determining the amount of sulphates and phosphates, it will be found that the organic albumin combinations containing sulphur and phosphorus all enter into solution, and that finally the sulphur and the phosphorus are again found as sulphuric and phosphoric acid. The next century will undoubtedly reveal many of the long-looked-for facts in the chemistry of the blood.

The Maniaco-Melancholic Insanity of Kraepelin.

—Dissatisfaction with the existing schemes of classification of mental diseases is constantly cropping out. This is inevitable. When scientists attempt to classify what they do not fully understand, the results are not altogether educational. As yet we do not fully understand the various forms of insanity—their etiology and pathology. Our knowledge is largely clinical, for it is based on a study of symptoms; it is not sufficiently profound to allow us to erect a classification on data which are truly fundamental. Thus it happens that some good alienists have almost ignored classification, as Sankey, for instance; while at the other extreme some of the

Germans have elaborated deeply involved schemes. A marked tendency toward simplicity in this matter has, however, been perceptible for some years. Sankey led this movement (or was in the van of it) when, in his text-book, he described "ordinary insanity," and included under this colorless term almost all the symptoms of mental disease. This was too iconoclastic, but it suited those simple-minded souls who have always maintained that Esquirol fathomed the whole subject when he divided insanity into Mania, Melancholia, Monomania and Dementia.

It is interesting now to note that these simpler methods are gaining credit even in Germany. Recently the eminent Jena alienist, Kraepelin, in his "Psychiatrie," has expressed some rather original views on the nosological position of mania and melancholia. By almost universal consent these two psychoses have been considered distinct. They are primitive and typical forms with almost every systematist. Each stands out separate and alone—one the antithesis of the other. This fact was the A, B, C, of psychiatry. But now Kraepelin (who will be listened to with respect) classifies the psychoses into acute, demential, and chronic; and in the first of these he includes the maniaco-melancholic insanity. In other words, he unites or fuses melancholia and mania into one clinical form, regarding these two states simply as phases of one identical disease. The essential character of this disease is the occurrence of symptoms of mental exaltation on the one hand, and of mental depression on the other, these symptoms appearing separately, or in irregular alternation, or simultaneously in a confused form. This disease arises on a basis of degeneracy—and here again Kraepelin departs from some of his confrères who have not considered the psychoses as forms of degeneracy.

The interesting point, and the one to which we call special attention, is the tendency here shown to cut loose from some of the old moorings. Many acute observers will agree that the affective moods, as marked by exaltation or depression, are not constant in numerous cases, and that after all they are not the disease itself. They are but phases of the troubled surface—the true pathological deeps are not yet explored. Still the fact remains that for all clinical purposes the old division into mania and melancholia will not be lightly ignored. The view of Kraepelin will, however, invite discussion, excite speculation, and incite to investigation, and out of these may come an increase of knowledge. Galdi, an Italian alienist, has recently subjected Kraepelin's views to a criticism, and this is abstracted in the *Journal of Mental Science* for April.

Reviews.

Points of Practical Interest in Gynecology, by H. Macnaughton-Jones, M. D., M. Ch., Q. U. I.; Master of Obstetrics (Honoris causa), Royal University of Ireland, etc.; Reprinted from the *Edinburgh Medical Journal*, 1900, with twelve plates. New York. William Wood & Company, 1901.

In this little volume of 124 pages are reprinted a series of communications from the pen of the distinguished author, which primarily appeared in the *Edinburgh Medical Journal*. They are six in number and include the following subjects: Some points in gynecological aseptis; some pitfalls in gynecological diagnosis; the therapeutics of disorders of menstruation; conservatism and its influence on operative technique; affections of the female genitalia as causal factors in the etiology of neuroses in insanity, and their special bearing on the operative treatment of the insane; and the indications for the operations of hysterectomy and myohysterectomy in myoma. Like all that emanates from the pen of Dr. Macnaughton-Jones, the material is absolutely up-to-date and full of instructive suggestions. Especially do we commend his attitude toward the so-called "brilliant" operating, in which he says that "deliberation and completeness are to be aimed at;" Too many men sacrifice these essentials in successful operating in their eager desire to appeal to the eye. In the performance of hysterectomy for fibroid tumor of the uterus the author is guided in his technique by the nature of the complications encountered, a list of which he appends to his article on that subject. Twelve handsome plates add to the value of the book, as well as an extensive bibliography bearing on the subject of sexual neuroses and insanity. [W. A. N. D.]

Essentials of the Diseases of Children.—By William M. Powell, M. D. Third Edition. Thoroughly Revised by Alfred Hand, Jr., M. D., Dispensary Physician and Pathologist to the Children's Hospital, Philadelphia. 12mo., 259 pages. Philadelphia and London: W. B.

Saunders & Company. Price \$1.00, net.

The Third edition of Powell's *Essentials of the Diseases of Children*, prepared by Dr. Hand, is thoroughly modern. The section upon the Infectious Diseases, which has been rewritten, contains many important details. The management of a case of contagious disease, to which a few pages are devoted, cannot fail to prove of great assistance to the young practitioner. The chapters upon the Diseases of the Stomach, Intestines, and Peritoneum are also well compiled. A new chapter upon Infant Feeding has been added, which embraces the essentials of that subject only, in a most concise manner. It is natural, in a compact book of this kind, that all subjects treated should be brief. One is therefore somewhat surprised to find the rarer diseases, such as perleche, Bednar's aphthae, Riga's disease, cyclic vomiting, glandular fever, and head-nodding mentioned. The three pages given to epidemic cerebro-spinal meningitis are well filled. In pathology and treatment, the book is quite up to date. The treatment of acute bronchitis is most concisely disposed of, in two short paragraphs. And it is interesting to note that mercury, as a laxative, in any of its preparations, is contra-indicated in all forms of stomatitis. Salol is not mentioned in the treatment of influenza, while phosphorus still holds a front place in the treatment of rachitis. The occurrence of functional heart murmurs, and of a venous hum over the jugular veins, is not given among the symptoms of chronic gastro-intestinal catarrh, though both are found under chlorosis. Nor is the appearance of craniotabes, given as a symptom of rickets, spoken of under syphilis or marasmus. The printing is singularly free from typographical errors, and the book is well made. It will, without doubt, be of use to the young physician, and to the medical student preparing for examination. [M. O.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Appointment.—Dr. S. Lewis Ziegler has been appointed a surgeon to the Wills Eye Hospital, in place of Dr. George C. Harlan, resigned.

Diphtheria is not "Quarantinable."—The Steamer Rhynland, from Liverpool and Queenstown, with three cases of diphtheria on board, was passed May 13th, by both the Federal and State quarantines and allowed to proceed directly to the city of Philadelphia. Although both the Federal and State authorities consider diphtheria contagious, they do not classify it as a "quarantinable" disease.

Philadelphia Lying-In Charity.—At the annual meeting of the contributors to the Philadelphia Lying-In Charity, Eleventh and Cherry streets, held May 8, one-third of the Board of Managers was elected to serve for three years. Stephen Green, Charles W. Warrington, Mrs. Gulielma. M. S. P. Jones, Hood Gilpin, Colonel Charles H. Howell and Mrs. Mary Warrington Stokes were re-elected. The Treasurer's report showed receipts for the year amounting to \$14,555.45, with \$14,698.70 disbursements, leaving a floating indebtedness of \$2170.10.

Sesquicentennial of the Pennsylvania Hospital.—Hundreds of friends and contributors to the Pennsylvania Hospital were present on Saturday, the 11th inst., to celebrate the 150 years of the Hospital's existence. Programmes were furnished narrating the simple exercises and containing a chronological list of the principal events in the history of the Hospital from May 11, 1751 to the present time. On the 18th inst. the invited guests will visit and inspect the well-equipped Department for the Insane, at 44th and Market streets. The separation of this department from the hospital proper took place in 1841. The exercises on Saturday last were held in the new Assembly building. T. Wistar Brown read St. Luke's version of the parable of the Good Samaritan. Benjamin H. Shoemaker, President of the Board of Managers extended a welcome to the "little provincial hospital" for which Franklin petitioned in 1751. Mr. John B. Garrett delivered the formal address. He paid a special tribute to the memory of those men prominent in the early history of the country who assisted in the establishing of the hospital and gave to it their substantial aid. Among those to whom he referred were John Morton and Benjamin Franklin, and in the later history of the institution, Wistar Morris and Dr. Kirkbride.

Pathological Society.—The first paper at the meeting of May 9 was the report by Dr. W. S. Wadsworth of a case of **ball-clot in the auricle. Death by occlusion.** The clot was spherical, and at least 2 inches in diameter, being perfectly free in the cavity. Death was sudden. The patient was an alcoholic who had been drinking heavily for 2 weeks, this being the apparent cause of the clot formation.

Dr. F. S. Pearce exhibited 2 specimens of hemorrhagic pachymeningitis and a tumor of the spinal cord. . . The lesion in the first 2 cases was unilateral and had not been diagnosed. The tumor of the dura which pressed upon the spinal cord in the lower thoracic region had also been undiagnosed, spastic paralysis of the lower extremities being the only symptom.

Dr. J. Walsh read a paper on **Diphtheria bacilli in noma.** The paper was a report of 8 cases of noma observed by Dr. Walsh at St. Vincents' Home during the past 2½ years. In every case the diphtheria bacillus was found. Four of these cases began as an ulcerative stomatitis. Other cases of stomatitis in which gangrene was not present were not found to contain the diphtheria bacillus. This would indicate that the important agent in these cases is not originally a saprophyte but the diphtheria bacillus. Dr. Joseph McFarland stated that he had experimentally produced a condition resembling gangrene by injecting cultures of the diphtheria bacillus. Dr. D. Riesmann said that the diphtheria bacillus was not the only cause of gangrene, as in a case of gangrene of the vulva no diphtheria bacilli were found.

Dr. W. W. Babcock exhibited **new apparatus**. These were 1. for rapidly filling tubes with cultures media, and 2. for washing gross specimens.

Dr. W. E. Hughes and Joseph McFarland exhibited a specimen of **Rupture of the aorta**. The rupture had occurred just above the heart.

Philadelphia Academy of Surgery.—At the regular meeting of May 6 Dr. R. H. Harte exhibited **three cases of empyema**. The importance of surgical interference in these cases was emphasized and the operative technic discussed. Dr. Harte advises the resection of at least 2 ribs and sometimes 3 for the purpose of securing ample drainage. A very large drainage tube should be employed. The opening should be made in the mid-axillary line. After operation a rise in temperature means that the tube is not draining properly or that a secondary pocket of pus is present. Even though the tube appears to be draining properly it should be removed and reinserted. If this is not effective remove the tube and insert a urethral sound, 22 or 23 French, and break up any pocket formations which may be present. Dr. R. G. Le Conte said that in cases where the chest was very much distended, the patients did not bear the operation well and a preliminary puncture should be made. Afterward a resection may be done. This view was also endorsed by Drs. Taylor, Wharton, Davis and Jopson.

Dr. W. J. Taylor read for Dr. W. W. Keen the report of **two cases of ligation of the external carotid**. The ligation in one case was for the control of obstinate hemorrhage following tonsillotomy. The second case was one of hemorrhage after an intra-nasal operation.

Dr. Lewis S. Mutschler read by invitation the report of **two cases of facial anthrax treated by carbolic acid injections**. The cases were undoubted anthrax as proven clinically and bacteriologically. The treatment consisted in the injection of 25 minims of pure carbolic acid in the tissues surrounding the lesion, the drug being introduced at 8 or 9 points. This was repeated the second day after, two injections sufficing. Bichloride dressings were applied. No internal treatment was instituted. Recovery followed in both instances. Dr. Jopson stated that these cases made in all 10 cases reported in Philadelphia. Dr. J. Chalmers Da Costa said that studies at the Jefferson Dispensary some few years ago demonstrated that tanners, etc., were subject to three lesions which must be differentiated. These are tuberculosis, sores due to the acids used, and anthrax. Dr. R. H. Harte said he saw no reason why cases of anthrax should be refused admission to the wards of general hospitals.

Dr. R. G. Le Conte reported the **ultimate result in a case of interscapulo-thoracic amputation for sarcoma**. Autopsy revealed the fact that the only metastasis was a growth the size of an orange in the lung of the opposite side.

Jefferson Medical College Commencement.—At the Public Commencement of the Jefferson Medical College held at the American Academy of Music on May 15, 1901, the Degree of Doctor of Medicine was conferred on one hundred and forty-two graduates by the President, Hon. William Potter, the exercises closing with a Valedictory by Prof. W. W. Keen, M. D., LL.D., F.R.C.S. (Hon.) The following prizes were awarded:

The Henry M. Phillips Prize of Seventy-five Dollars. Awarded upon the recommendation of the Professor of Medicine to the graduate in his opinion most worthy, to James Edwin Weller, of Indiana.

The Henry M. Phillips Prize of Seventy-five Dollars. Awarded upon the recommendation of the Professors of Surgery to the graduate in their opinion most worthy, to Albert B. Craig, of Washington.

Physiology Prize. Awarded by bequest of Dr. Francis W. Shain, for the best Essay or the best Examination on a subject pertaining to Physiology (open to undergraduates of the second year), to Undergraduate Thomas Cook Stellwagen, Jr., of Pennsylvania.

Chemistry Prize. A Gold Medal, for the best Original

Work in the Chemical Laboratory (open for undergraduates), to Undergraduate Max R. Dinkelspiel, of New York.

Therapeutics Prize. A Gold Medal, for the best Examinations in Therapeutics, to Acheson Stewart, of Ireland.

Obstetrical Prize. A Gold Medal, for General Excellence in Obstetrics, to George A. Ulrich, of Pennsylvania.

Anatomy Prize. A Gold Medal, for the best Anatomical Preparation (open to undergraduates), to Undergraduate Thomas Cook Stellwagen, Jr., of Pennsylvania.

Ophthalmology Prize. By Professor De Schweinitz, a Gold Medal, for the best Examination on Ophthalmology, to Pascal Brooke Bland, of Pennsylvania, with honorable mention of William Carey Vail, of Indiana, and Theodore T. Girould, of Illinois.

Gynecology Prize. By Professor Montgomery, a Gold Medal, for the best Examination in Gynecology, to Collin Foulkrod, of Pennsylvania, with honorable mention of George A. LaMotte, of Missouri.

The W. S. Forbes Anatomical League Prize of One Hundred and Fifty Dollars given by Professor Forbes to the member of the Anatomical League having the highest standing in a competitive Examination in Anatomy, to Louis C. Williams, of New Jersey, with honorable mention of Douglas Symmers, of South Carolina.

Clinical Orthopedics Prize. By Professor H. Augustus Wilson, Twenty-five Dollars for the best Examination in Orthopedic Surgery, to Albert B. Craig, of Washington.

Clinical Pediatrics Prize. By Professor Graham, Twenty-five Dollars for the best Report on his Clinics, to Louis C. Williams, of New Jersey, with honorable mention of J. B. Horiinstein and Joseph Weller.

Clinical Neurology Prize. By Professor Dercum, Twenty-five Dollars, for the best Examination in Neurology, to William C. Vail, of Indiana, with honorable mention of George A. LaMotte, of Missouri.

Clinical Genito-Urinary Prize. By Professor Horwitz, Twenty-five Dollars, for the best Examination in Genito-Urinary Surgery, to George A. LaMotte, with honorable mention of Robert G. Davis.

Clinical Obstetrics Prize. By Professor Davis, Twenty-five Dollars, for the best Report of his Clinics, to George Althouse LaMotte, of Missouri, with honorable mention of Collin Foulkrod, of Pennsylvania, and Francis Wayland Goddard, of Pennsylvania.

Clinical Ophthalmology Prize. By Professor Hansell, Twenty-five Dollars, for the best Report of his Clinics, to J. Leslie Davis, of Kentucky.

Clinical Otolaryngology Prize. By Professor S. MacCuen Smith, Twenty-five Dollars, for the best Examination in Otolaryngology, to J. Leslie Davis, of Kentucky, with honorable mention of William C. Vail, of Indiana, and Collin Foulkrod, of Pennsylvania.

Clinical Dermatology Prize. By Professor Stelwagon, Twenty-five Dollars, for the best Examination in Dermatology, to W. C. Vail, of Indiana, with honorable mention of George A. LaMotte, of Missouri.

Clinical Laryngology Prize. By Professor D. Braden Kyle, Twenty-five Dollars, for the best report of his Clinical Lectures, to Collin Foulkrod, of Pennsylvania.

Clinical Laryngology Prize. By Professor Jones, Twenty-five Dollars for the best Report of his Clinics, to J. Leslie Davis, of Kentucky, with honorable mention of Louis C. Williams, of New Jersey.

Alumni Prize. By the Alumni Association, a Medal for the best General average gained in the Examinations for the entire curriculum, to George Althouse LaMotte, of Missouri.

W. B. Saunders Prize. Ten Volumes of Saunders' Medical Hand Atlases, to the student who passes the best General Examination at the close of the College term, to Collin Foulkrod, of Pennsylvania.

Out-Patient Department Obstetric Prize. By Dr. W. H. Wells, Demonstrator of Clinical Obstetrics, a Case of Instruments, for the best Report of work in out-patient maternity service, to George Burton Angle, of Texas.

The S. McCuen Smith Prize of Two Hundred Dollars. Awarded by Professor Smith, upon the recommendation of a Committee, for the best Essay embodying original research "On the Discharge from the Ear, with Special Reference to Intra-Cranial Lesions," to John Funke, Pennsylvania.

Ptolemy Prize. A Gold Medal, by the Ptolemy Society, to the student of the Graduating Class who passes the Examinations of the Senior year with the highest general average, to Collin Foulkrod, of Pennsylvania.

Philadelphia County Medical Society.—At the meeting of May 8, Dr. Simon Baruch of New York read a paper on *Lessons of a Decade in Hydrotherapy*. Dr. Baruch stated that of the remedies in use during the time of Hippocrates two now remained—venesection and water. Water is used for the purpose of conveying temperature and thus to produce the effects of temperature changes. The medical profession has been backward in the employment of cold water because of the erroneous idea that it produces shock. On the contrary it produces the opposite effect when judiciously used. In deciding upon the dosage 3 elements are to be considered—duration, temperature, and pressure. The circulation is under the control of water at a proper temperature as proven by experiments upon animals when portions of the brain were exposed. The desired effect of cold water is the enhancement of the resisting powers of the individual. In typhoid fever the peripheral resistance and the circulation in general is increased by the stimulation of the peripheral nerve filaments. When the teeth of a typhoid patient in the cold bath begin to chatter the bath should be stopped. If the patient shivers but the teeth do not chatter the bath need not be stopped but friction should be increased. Under no circumstances should the ice coil be applied to the abdomen. In chronic diseases cold baths deepen inspiration and increase the heart's action thus sending an increased amount of hemoglobin and blood cells to the periphery of the body and also to the lungs. This increases the oxygenating power of the individual. In the treatment of tuberculosis hydrotherapy should supplement dieting and open air life. The good results of hydrotherapy in this disease are traceable to the stimulating effect of cold on the nervous system. In neurasthenia a large proportion of cases are benefited and not a few cured by hydrotherapy where there is no organic lesion associated. Dr. Baruch gave in detail the method of treatment. Hydrotherapy is of value in diabetes, especially in obese patients. The glycogenic function of the liver can be influenced but little, but the glycogen in the voluntary muscles plays a large part in the disease. The amount of sugar can be decreased by paying attention to the muscles in the way of exercise and the improvement of the circulation by the use of cold water.

Dr. Wharton Sinkler read a paper on *The effect of the douche in neurasthenia and other Nervous Troubles*. Dr. Sinkler spoke of the good results from the use of hydrotherapy in nervous affections. His method of employing it is practically the same as that of Dr. Baruch. It is particularly valuable in combatting the insomnia of neurasthenia. Exercise after the bath is a very important matter. Dr. S. Solis Cohen spoke in confirmation of Dr. Baruch's advocacy of hydrotherapy. He believes that every medical center should support an institution for the application of hydrotherapy, pneumotherapy, massage, and electrotherapy. Dr. J. H. Musser stated that the term "cold friction bath" as used by Dr. Baruch was a most happy one and much more impressive than the term "cold bath." The belief in the efficacy of hydrotherapy in the treatment of typhoid fever is becoming stronger every day. He hopes to see the hydriatic treatment of tuberculosis increase in use and value. Dr. Pearce read for Dr. J. M. Anders his discussion on the subject in question. Dr. Anders spoke of its value in neurasthenia and typhoid fever. He also said that in actual conditions where there was an overwhelming toxemia large draughts of water acted as a diuretic and were thus useful in ridding the body of the toxins present.

In closing the discussion Dr. Baruch said that in treating insomnia by the use of water certain precautions must be taken. Warm water dilates the capillaries. If the patient then comes in contact with cooler air this dilatation is

counteracted and the patient is weakened. Hence instead of allowing this chilling of the surface the patient should be wrapped in warm sheets and blankets and then placed between warm sheets and hot water bottles applied. A still better way is to give a cold wet pack. Dr. Baruch said that the diuretic effect of water was not due to simple flushing of the kidneys. It acts in the stomach as it does on the skin, causing a contraction and then a dilatation of the vessels. This, through action on the nerves, stimulates respiration and the systole of the heart. In this way diuresis is brought about. Because of this fact the giving of 1 or 2 ounces of water at 40° every 2 hours will produce more diuresis than will the giving of one-half a pint.

Dr. R. G. Le Conte read a paper on *The value of combined medical and surgical clinics to the student*. Dr. Le Conte claims that a purely medical or surgical clinic gives only a one-sided view of many cases and the student does not get a connected idea of the case. Several combined clinics were given at the Pennsylvania Hospital during the past winter, with a great degree of satisfaction to clinicians and students.

College of Physicians of Philadelphia.—The meeting held May 1 was devoted to the discussion of *The relation of diseases of the heart to surgical operations, and especially to the use of general anesthetics*. The first paper was read by Dr. W. J. Mayo, of Rochester, Minn., on *Pre-existent heart disease, in reference to surgical operations*. Dr. Mayo said that the condition of the heart muscle was of prime importance to the surgeon and the reserve power of the heart so far as is possible, must be estimated and taken into consideration. Will it stand the anesthetic, the blood loss, the nerve shock, of the operation? The reserve power of the heart is commonly thought to be less in infancy and in old age. Dr. Mayo finds this to be more true in regard to the former period than in the latter. His experience does not enable him to substantiate the statement that people above the average height bear anesthetics badly. Many people in the Northwest are above the average in height and they take anesthetics excellently. Valvular lesions of the heart are usually well compensated in persons between the ages of 10 and 40 years and there is generally little risk in giving them an anesthetic. If failing compensation is present, only the most urgent operations should be done before treatment has been instituted. After 40 valve lesions are usually associated with myocarditis. The most dangerous lesion is fatty degeneration. Dr. Mayo believes that many of the unexpected and sudden deaths which occur soon after operation are due to myocardial change. Cases were cited in illustration of this point. Some of the cases of death following operation for exophthalmic goiter are undoubtedly due to myocarditis incident to that disease. The one death in 7 thyroidectomies done by Dr. Mayo was due to that cause. A knowledge of cardiac insufficiency by the surgeon and anesthetizer is a great safeguard against danger during an operation. Dr. H. A. Hare spoke on *The safest anesthetic to use in organic disease of the heart and vessels*. Dr. Hare said that comparatively few people having heart disease died from the effect of an anesthetic as compared with the deaths from straining at stool, going rapidly up stairs, etc. The majority of the accidents in surgery are due, not to the anesthetics, but to the shock of the operation. He has seen the condition of the patient improve under the influence of the anesthetic. The question of poisoning by these drugs must be taken into consideration. Probably not more than 1 surgeon in 100 knows how much anesthetic his patient really receives. The quantity poured on the inhaler is not the true amount and for this reason the dosage is unknown. In choosing an anesthetic the idiosyncrasy of the patient is often not taken into account. The statement of Dr. Mayo in regard to persons of overheight may apply to the hardy races of the Northwest, but it does not to people in this locality. Dr. Hare laid great stress on the condition of the vessels in regard to the use of anesthetics. Ordinarily the clinician or surgeon examines the heart but does not investigate the cardio-vascular tone, blood pressure, etc. In many cases of high arterial tension, ether is contraindicated, although generally it is the safest anesthetic we have. American surgeons do not often enough use stropline for its effect in checking secretion caused by the anes-

thetic. The choice of method of giving an anesthetic is as important as the choice of the anesthetic itself. The inhaler to which a rubber bag is attached and which causes the patient to breathe his own respired air should never be used. The giving of an anesthetic by means of oxygen bubbling through it is a disadvantage. If chloroform be used a chemical change may take place and ether is rendered more combustible. If it is desirable to increase the oxygen the anesthetic is increased at the same time while a decrease in oxygen means a decrease in anesthetic. Too much oxygen will produce apnea. The oxygen should be given alone and the anesthetic alone as it is only by this means that a proper amount of each is used. Ether is the safest anesthetic except in cases of vascular disease. It is not strongly contraindicated in Bright's disease. Chloroform in cases of myocardial change is often dangerous. Nitrous oxide is contraindicated when vascular changes are present. In regard to the use of a general anesthetic in cases having valvular and myocardial disease, Dr. Hare said that the patient often improves under the use of the anesthetic. General anesthesia is better than local or spinal anesthesia. Shock to the nervous and circulatory systems is greater in the latter method and patients have been seen to improve when it was abandoned and general anesthesia used. In Dr. Hare's opinion intraspinal injection will soon be a medical curiosity. Dr. Finney exhibited charts which he has the anesthetizer keep for each case. These show the pulse frequency at each 5 minutes during the operation. Dr. Alfred Stengel spoke of **The cardiac complications which may arise after operation.** There is very little to warrant the belief that anesthetics will produce a heart lesion except of the myocardium. For the immediate effect inferences should be drawn from examinations with no blood loss, and from trivial operations. In pre-existing myocardial change ether is well borne. Some cases show an improved cardiac condition immediately after operation. After some days a weakness may develop. Pneumonia is often said to be due to aspiration, irritation, etc., when it is due to a failing circulation and anesthesia has been the exciting cause. Pneumonia embolism is more frequent in gynecological cases. The heart is the predisposing cause. Myocardial disease is common in women who have myomata of the uterus. Dr. Stengel emphasized the necessity of recognizing that pneumonia, late vomiting, embolism, etc., are in some cases really due to the failure of the operator, causing sepsis, etc. Dr. Ochsner, of Chicago, stated that he had never had an alarming condition from anesthesia in patients suffering from a demonstrable heart lesion. A paper by Dr. R. G. LeConte entitled **Hydatid disease of the breast** was read by title.

Philadelphia Obstetrical Society.—At the stated meeting held May 2, Dr. Frank W. Talley reported **A case of puerperal septicemia treated with Unguentum Crede.** In addition to treatment by whiskey, strychnine, etc. in an undoubted case of septicemia, Crede's ointment was used by inunction. Improvement was noticed the morning after its use was begun. On the fifteenth day the temperature was normal and the inunctions were discontinued. The temperature rose again in 5 days reaching 102°. Inunctions were again used and the temperature was normal by the second day. In all 3 ounces of the ointment were used. Dr. J. M. Baldy said that cases of septicemia were deceptive, sudden changes often taking place. He does not see that the silver ointment can do any good in such cases. Dr. Chas. P. Noble stated that a large percentage of the cases of puerperal septicemia recover. He has never used silver ointment but it is worthy of note that Dr. Talley used other approved methods of treatment in his case. Dr. Stricker Coles uses whiskey, strychnine, sponging, etc. and has had no fatalities in 8 cases. Dr. J. M. Baldy reported three cases and exhibited specimens. Case 1 was an apparent calcareous degeneration of both ovaries but histological examination showed it to be a fibrous change, the tissue being remarkably dense. Case 2 was an adenocarcinoma of the fundus of the uterus. Case 3 was an ovarian cyst.

OBITUARY.

Dr. Andrew K. Minnich.—Dr. Andrew K. Minnich died May 11, at his residence, 145 Susquehanna avenue, in his 54th year, after an illness of six months. Dr. Minnich was born in Mount Joy, Pa. He was graduated with honors from Lafayette College, and then entered the Jefferson Medical College, from which he was graduated in 1870.

The Franco-German War was in progress at that time, and he enlisted as surgeon in the German army. At the close of the conflict he was induced to return to this city as a teacher and lecturer in the Wagner Institute of Science. For more than twenty years Dr. Minnich was a visiting physician to the Episcopal Hospital, and for many years was quiz-master and lecturer in the Jefferson College. He contributed many valuable treatises on blood disease. He was a member of the Medical Club, Philadelphia County Medical Society and Metropolitan Club.

Dr. Julius Boushey, at San Francisco, Cal., on April 29.—Dr. George Cyprian Jarvis, at Hartford, Conn., on May 7, aged 67 years.—Dr. E. L. Priest, at Nevada, Mo., on May 8.—Dr. M. E. Downes, at Wilmington, Del., on May 10.—Dr. H. D. Peters, at Henry County, Md., on May 10, aged 84 years.—Dr. Daniel Humphrey, at Lawrence, Mass., on May 9, aged 79 years.—Dr. E. Stanley Perkins, at Philadelphia, Pa., on May 6, aged 59 years.—Dr. Robert Bolling, at Chestnut Hill, Philadelphia, Pa., on May 12, aged 68 years.—Dr. Charles Rice, at New York City, on May 13, aged 60 years.—Dr. Norman Armett Smith, at Greenwich, Conn., on May 12, aged 78 years.—Dr. George W. Pembroke, at Friendship, Md., on May 12, aged 58 years.—Dr. James Hayes, Plainfield, N. J., on May 13.

Vital Statistics of Philadelphia for the week ending May 11, 1901:

Total mortality	475	Cases.	Deaths
Inflammation of the appendix 3, bladder 2, brain 9, bronchi 6, heart 2, kidneys 16, larynx 2, lungs 71, peritoneum 9, pleura 3, stomach and bowels 21, uterus 1, spine 1 ..			146
Marasmus 13, debility 8, inanition 16			37
Tuberculosis of the lungs			62
Apoplexy 15, paralysis 5			20
Heart-disease of 36, fatty degeneration of 1, neuralgia of 3			40
Uremia 14, diabetes 1, Bright's disease 3			18
Carcinoma of the breast 1, stomach 4, uterus 5, larynx 1			11
Convulsions			15
Diphtheria			14
Brain-abscess of 1, congestion of 2, disease of 2, tumor of 1			6
Typhoid fever	98		12
Old age			10
Cyanosis			2
Scarlet fever	101		6
Influenza 1, abscess of lungs 1, alcoholism 6, asthma 3, anemia 2, burns and scalds 2, carbuncle 1, casualties 5, congestion of lungs 4, child birth 1, cholera morbus 1, cirrhosis of the liver 3, croup 1, croup, membranous 1, diarrhea 1, drowned 4, dysentery 1, epilepsy 2, fever, malarial 1, puerperal 1, hemorrhage from uterus 2, gangrene 2, jaundice 1, locomotor ataxia 2, lymphadenoma 1, measles 4, obstruction of the bowels 2, edema of lungs 2, poisoning 1, rheumatism 2, shock 2, septicemia 2, sarcoma, multiple 1, suffocation 1, suicidal, tetanus 1, ulceration of the stomach 1, unknown coroner case 1, whooping cough 3			74

NEW JERSEY.

Smallpox Epidemic at Gloucester City.—Considerable excitement prevails in Gloucester City on account of the epidemic of smallpox which exists there. All cases have been isolated and rigid sanitary measures have been instituted. There is no positive knowledge as to how the disease was introduced in Gloucester City, but the first case, who is a native of the city, is said to have repapered the house in Woodbury in which the only fatal case of that town occurred. The superintendents of mills and factories have insisted upon general vaccination of the employees.

NEW YORK.

New Lunacy Commissioner.—Governor Odell has appointed Dr. Frederic Peterson, of New York City, the Medical member of the State Lunacy Commission, to succeed Dr. Wise. Dr. Peterson was largely instrumental in the organization of the Craig Colony for Epileptics, and is president of the Board of Managers of that institution.

Dr. Charles Rice, Chairman of the Revision Committee of the United States Pharmacopeia, died May 13th., at Bellevue Hospital, N.Y. Dr. Rice was born in Munich in 1841. He received an education in Vienna, Munich and Passau, acquiring a thorough mastery of several Oriental languages, the classics and the modern tongues. He was a most thorough and accomplished linguist and recognized as an authority on questions of philology and etymology. Dr. Rice came to America in 1862, and during the war served in the navy as surgeon's steward. After his discharge from service he entered the Department of Public Charities and Corrections of New York City, and has been the chemist to that department and superintendent of its drug department for many years.

Appointment.—Dr. L. Emmett Holt has been appointed Clinical Professor of Diseases of Children at the College of Physicians and Surgeons, New York.

Home for Chronic Invalids.—The Montefiore Home for Chronic Invalids, of New York, has maintained a sanitarium for consumptives at Bedford Station, Westchester County, for several years. It has now widened its scope by adding a new building capable of accommodating upward of 150 patients. This building is nearing completion, and will be formally opened on Memorial Day, Thursday, May 30.

Appointment.—Dr. Louis Fischer has been appointed a Visiting Physician to the Willard Parker and Reception Hospitals of New York City.

Dr. Samuel K. Lyon.—Dr. Samuel K. Lyon, who has been a police surgeon for thirty years, died suddenly May 4th. in New York City. He was a graduate of the College of Physicians and Surgeons, and a member of the County Medical Association, the Academy of Medicine, and the County Medical Society.

Edward N. Gibbs Memorial Prize Fund.—The Trustees of the New York Academy of Medicine have the pleasure of announcing the receipt of Ten Thousand Dollars from Mrs. Sarah Barker Gibbs and Miss George Barker Gibbs, for the establishment of The Edward N. Gibbs Memorial Prize Fund, the income to be awarded triennially to the physician of regular standing in the medical profession of the United States of America, who shall present the best original essay upon the etiology, pathology and treatment of the diseases of the kidney.

Manhattan Dermatological Society.—The regular monthly meeting was held on Friday evening, May 3d, at the residence of Dr. A. Bleiman, No. 206 E. 48th St. Dr. Wm. S. Gottheil presided. Dr. R. Abrahams presented a patient with *tinea, versicolor* limited to the palms. The lesion had existed for a year and a half and when first seen consisted of light and dark yellow patches of various shapes and sizes. Sweating was noticed during the summer months and but little during the winter. The lesions were more perceptible with daylight. At present, owing to the constant washing, the palms simply showed a superficial scalliness. Microscopical examination by Dr. Gottheil demonstrated typical mycelia and spores of the microsporon. Apart from the case of Dr. Gottheil, this is the only one recorded. Dr. Gottheil remarked that although from a clinical standpoint this case was not as characteristic as his own, the microscopical picture was classical. Dr. Bleiman said that at present the case looked like *tellositas*, and Dr. L. Weiss that it resembled a chronic eczema. Dr. J. Sobel recommends the application of Leyol's solution for bringing into view pale and imperceptible lesions of the disease (Allen's Test.) Dr. E. L. Cocks presented two cases of *prurigo* in a native born boy and girl of eight and nine years respectively. These cases would refute the statement of Hyde and White that this disease occurred only in foreign born individuals. Both presented papules on the exterior surfaces of the extremities, the feeling of a nut-

meg grater and enlarged glands. Both gave a preurticarial history. Dr. Kinch agreed with the diagnosis. Dr. R. Abrahams would call both chronic urticaria and advise pilocarpine. Dr. S. Sobel remarked that neither case corresponded to his conception of *prurigo* nor to the cases as he had seen them abroad. The papules lacked a certain firmness, he could not detect the nutmeg grater feeling, the *prurigo* buboes were wanting. He would call both chronic papular articularia. Dr. L. Weiss said the preurticarial state might speak for *prurigo*. Against it were the absence of haggard look and anemia, and the *prurigo* buboes. He would call them lichen urticatus or chronic lichen simplex. Dr. Oberndorfer stated that neither case looked like *prurigo*. He missed the great infiltration of the skin, the hardness of the individual lesions and the characteristic glandular enlargement. He calls it chronic popular eczema.

Dr. Gottheil said the picture was not quite that of *prurigo* or popular urticaria. He inclined however toward a diagnosis of *prurigo*.

Dr. Weiss presented a case of *eczema neuroticum vegetans*. The patient showed symmetrical lesions of the lower extremities; there were patches with healed centres, the individual lesions being small, elevated papules resembling lichen. Dr. E. L. Cocks considers it lichen planus on an eczematous base. Dr. Oberndorfer fails to see lichen planus. Eczema is his diagnosis. Dr. Bleiman believes the primary condition to be *pruritus senilis*. Dr. J. Sobel would call this condition a mycotic eczema. For this speak the more or less circular form, the somewhat sharply defined edges, the healed centre, the persistency of the lesions. Chrysarbin and formalin act well. Dr. R. Abrahams excludes lichen planus, *pruritus*, and neurotic eczema, and diagnoses a parasitic eczema. Carbolic acid and strong silver colution (50%) are advised. Drs. Gottheil and Kinch consider it eczema.

Dr. L. Weiss presented a *rosacea* of the cheeks; upon stretching the skin the capillary dilation and circulation became apparent. Dr. Geyser advised the use of a fine steel needle attached to the negative galvanic pole and inserted at right angles into the vessels. Dr. A. Bleiman presented a girl of twenty-three with *favus* of the nails of the left hand. There were lesions of *favus* on the scalp. Dr. Kinch did not find much evidence of *favus* on the scalp. Drs. Oberndorfer, Gottheil and Cocks would expect more destruction of hair in a *favus* of such duration.

Dr. Oberndorfer showed a patient with a probable *acne varioliformis* of the scalp and neck, together with a number of bald spots of the head. Many lesions were not characteristic. Dr. R. Abrahams would call the condition *acne vulgaris* with folliculitis.

Dr. J. Sobel calls it *acne pustulosa* and folliculitis abscedens. Dr. L. Weiss said that the bald spots speak for folliculitis decalvans. Dr. E. S. Cocks does not consider it *acne varioliformis*. Dr. Ochs presented a patient with resolving syphilis. Dr. A. Bleiman showed a *pityriasis rosea*, resembling seborrheal eczema and a case of *scabies*, showing the continuous treatment of the disease with Wilkinson's ointment.

WESTERN STATES.

National Confederation of State Medical Examining and Licensing Boards.—At the next meeting of the National Confederation of State Medical Examining and Licensing Boards to be held at St. Paul, Minn., June 3rd, 1901, there will be a discussion of the question: "What should be the legal definition of the practice of medicine?" following a paper on that subject by Dr. Henry Beates, Jr., of Philadelphia. Also a discussion following the report of the Committee on Interstate Reciprocity and Uniform Medical Legislation.

Meeting of the American Medical Editors' Association.—The annual business meeting of the American Medical Editors' Association will convene in the library rooms of the Ramsey County Medical Society, Lowry Arcade building, St. Paul, at 2.30 P. M., Monday, June 3d. The Lowry Arcade building is situated in St. Peter street, between Fourth and Fifth. The session will open promptly at the above hour, and all members are urged to be present at that time.

This association, as implied in the name, consists of medical editors of the United States. Meetings are held

annually, coincident with the American Medical Association. The aims of the association are the advancement of medical journalism, the foundation of an ethical press in medicine, and the improvement of the medical profession in general. The membership includes the leading medical writers and editors of the country.

The meeting this year will be a most successful one, both from the point of presentation of valuable papers and the energetic work of the members of the association which will be made manifest at the meeting. The preliminary program is calculated to interest and benefit every medical editor. A partial list of papers includes:

President's Address, Dr. Alex. J. Stone, of St. Paul.
Relative Value of Medical Advertising, by Dr. John Puntton, of Kansas City, Missouri.

Paper, subject unannounced, by Dr. John V. Shoemaker, of Philadelphia.

Improvements in Medical Education, by Dudley S. Reynolds, of Louisville.

Some Thoughts on the Ethics of Medical Journalism, by Burnside Foster, of St. Paul.

Editorial Corps and Medical Journalism, by Dr. George F. Butler, of Alma, Michigan.

Relation of the Medical Editor to Original Articles, by Harold Moyer, of Chicago; and

Paper, subject unannounced, by Dr. George H. Simmons, of Chicago.

The annual dinner of the association will be held at 9 P. M., June 3d, reservation of plates should be made at once. Membership applications and titles of additional papers can be sent to Alexander J. Stone, Lowry Arcade, St. Paul, president, or O. F. Ball, Century building, St. Louis, secretary.

Not Obligated to Attend Patients.—The supreme court of Indiana has recently decided that a licensed physician is not legally obliged to attend a patient when called, although he has been the family physician of the patient in times past. Dr. Weddingfield refused to attend a patient, although he had been called three times. The patient died, and it was charged that her death was caused by the doctor's refusal to respond to the call. He was sued for \$10,000 damages.—*Western Medical Review.*

Mississippi Valley Medical Association.—It is announced that the dates of the next meeting of the Mississippi Valley Medical Association have been changed from the 10th, 11th, and 12th of September to the 12th, 13th, and 14th of September. This change has been necessary because the dates first selected conflicted with another large Association meeting at the same place.

The meeting is to be held at the Hotel Victory, Put-in-Bay Island, Lake Erie, O., and the low rate of one cent a mile for the round trip will be in effect for the meeting. Tickets will be on sale as late as September 12th, good returning without extension until September 15th. By depositing tickets with the Joint Agent at Cleveland and paying 50 cents the date can be extended until October 8th. This gives members an opportunity of visiting the Pan-American Exposition at Buffalo, to which very low rates by rail and water will be in effect from Cleveland.

Full information as to rates can be obtained by addressing the Secretary, Dr. Henry E. Tuley, No. 111 West Kentucky street, Louisville, Ky. Members of the Profession are cordially invited to attend this meeting.

Those desiring to read papers should notify the Secretary at an early date.

A Bill introduced by Mr. Stubblefield for an act requiring reports of births and deaths, and the recording of same; regulating the interment or other disposal of dead bodies, and prescribing a penalty for non-compliance with the provisions hereof, has passed both Houses in the State of Illinois and will go into effect January 1, 1902.

Pleads Guilty.—Stephen A. Weltmer and Joseph H. Kelly, former president and secretary of the Weltmer Institute of Magnetic Healing, at Nevada, Mo., who recently pleaded guilty to indictments charging them with using the mails to defraud, were each fined \$1,500 by Judge Phillips, in the United States District Court. The men gave "absent treatment," and their mail, which reached a tremendous volume, was stopped by the Postoffice Department at Washington on a fraud order.

Smallpox in California.—Eighteen cases of smallpox have broken out at the State institution for the deaf, dumb and blind, at Berkeley, Cal.

SOUTHERN STATES.

Women Doctors in South Carolina.—Two young women have recently been graduated from the Medical College of South California. They are the first women graduates of the institution and also of the State.

Dr. Stanford E. Chaille, dean of the medical department of Tulane University, in New Orleans, has been given the degree of LL.D. by the university on his completion of fifty years in its service.

Medical Springs.—The Secretary of the Interior has addressed letters to the Governor of each State in the Union asking for detailed reports as to the safeguards thrown about thermal and medical waters within the borders of the states. He seeks the information for the International Commission of Medical Hydrology which will meet in Berlin shortly.

Meeting of the American Therapeutic Society. (Reported by Dr. T. L. Coley).—The second annual meeting of the society was held in Washington, on Tuesday morning, May 7th, at 10 o'clock. In the absence of Dr. H. C. Wood, who was prevented from attending on account of illness, the meeting was called to order by the vice-president, R. W. Wilcox, of New York. Dr. Robert Reyburn, chairman of the Judicial Council, delivered the address of welcome. Dr. T. E. Satterthwaite, of New York, responded on behalf of the visiting members. The reports of the secretary and treasurer followed. Dr. George C. Ober, of Washington, delivered a memorial address upon the late Dr. Samuel C. Busey, of Washington. The morning session was then adjourned. The Judicial Council met at 12 o'clock. The afternoon session convened at 2 o'clock and the president's address, "Reviewing the Progress of Therapeutics for the Preceding Twelve Months," was delivered by Dr. R. W. Wilcox. A business meeting behind closed doors followed. In the evening the District Therapeutic Society gave a reception at the Cochran. At the morning session of May 8th, Francis G. Morgan, M. D., of Washington, read a paper on "Suggestions Concerning the Use of the Metric System in Prescription Writing," and an interesting discussion followed. Dr. F. E. Stewart, of New York, read a paper on "The Relation of the Pharmacist to the Physician, and the Relation of Pharmacy to Materia Medica and Drug Therapeutics." This paper was of especial interest on account of Dr. Stewart's well-known advocacy of the idea for the establishment of a National Bureau of Materia Medica. Dr. Stewart called attention to the necessity of regulating the papers to be read before the society in such a manner that it would be impossible to permit commercial interests to assume control or allow the society to be used for advertising purposes. On the other hand, it should be permissible for the results of all truly scientific investigations upon pharmacology to be submitted to the society, but care must be taken that no drugs are discussed under their copyright names but under their chemical designations. He made an urgent plea for the establishment of a National Bureau of the Materia Medica, and desired that the American Therapeutic Society should be known as strongly advocating this measure. The matter was referred for favorable consideration to the Judicial Council. Dr. Robert Reyburn, of Washington, read a paper upon

Importance of Petroleum in Therapeutics When Given Medicinally. The good effects of petroleum when obtained, the writer believed to be due to its emulgent and lubricating qualities. It also aids general absorption by increasing peristalsis, but the drug is not absorbed. Dr. Albert C. Barnes, of Philadelphia, stated that it is well known that petroleum is not absorbed in the gastro-intestinal tract, but a remedy may have the most pronounced physiological effects purely upon account of its mechanical properties. He quoted Dr. Robinson, of Philadelphia, who had treated over 50 selected cases in which nutrition, digestion and body weight were impaired and the purest oil administered for periods of several months. There was in every instance increase in weight and improvement in health. The fact that petroleum passes through the intestine in the original form and that it has been proven to be a solvent of many remedies administered for their antiseptic and astringent influence indicate a useful field for petroleum as a vehicle. In closing Dr. Reyburn expressed his conviction that the petroleum was in no sense a substitute for cod liver oil. At the afternoon session Dr. T. E. Satterthwaite, of New York, discussed

"The Therapeutics of Chronic Heart Diseases and their Complications." He placed especial stress upon the fact that the condition of the cardiac muscle and the cardiovascular system generally was far more important than the precise valvular lesion, and he placed more dependence upon exercise alternating with periods of rest and upon the bath treatment, with strychnia and heart tonics given only as indicated, than upon the total rest in the treatment of these conditions. Eli H. Long, M. D., of Buffalo, contributed a paper upon the "Principles of Cardiac Therapeutics in Recent Valvular Disease." On account of the absence of Dr. Long, the paper was read by the Secretary. J. N. Hall, M. D., of Denver, read "A Report of Two Cases of Aneurysm Treated by Wiring and Electrolysis." These cases illustrated the great benefits to be derived from this method when gelatin and other treatment have proven unavailing, and the location of the aneurysm is suitable for the operation. In the evening a banquet was served at the Cochran. At the morning session of May 9th, Francis H. Miner, M. D., of Washington, discussed "Hypnotism; a Practical Demonstration of its Therapeutic Value." Dr. Miner exhibited a patient whom he could hypnotize very readily, and who was extremely susceptible to post-hypnotic suggestion. He had been an inveterate smoker, and had been cured by post-hypnotic suggestion. At this point in the proceedings a discussion arose as to the advisability of permitting the next paper on the program, "The Therapeutic Use of Chlorotone," to be read under that title. Dr. Stewart remarked that the drug is covered by a patent, and the right to the use of the name chlorotone is limited to one firm of manufacturers. Dr. Barnes, of Philadelphia, believes that the attitude of the physician toward remedies covered by patent, copyright or fanciful name should be unequivocally decided at this meeting. If the society is to be made a place of discussion for patented remedies it will soon lose its usefulness as a scientific body. Dr. Barnes stated that this drug is not a new product. It was first produced in Germany by Willgerodt in 1888 and scientifically investigated by Kossak and Rudolf, and, as Eichengrün states, is shown to be dangerous as an internal remedy because of its strong depressing influence upon blood pressure. The product has been sold for years in Germany under the name of Aneson. Dr. Barnes therefore moved; "that any therapeutic agent offered for discussion before the society should be discussed under its chemical name, and not under its fanciful patented or copyrighted commercial name." This motion was unanimously passed by the Society. Dr. Wilcox therefore instructed Dr. Houghton to discuss the preparation under the name Acetone-Chloroform, which is its chemical name. Dr. E. M. Houghton, of Detroit, then read a paper on "The Therapeutic Use of Acetone-Chloroform. This drug, he declared, was of value as a local anesthetic, a hypnotic and an antiseptic, and from his studies he believed that it was perfectly safe and adapted to general employment.

At the afternoon session the following officers were elected: President, Reynold W. Wilcox, M. D., New York, N. Y.; first vice-president, Howard H. Barker, M. D., Washington, D. C.; second vice-president, Eli H. Long, M. D., Buffalo, N. Y.; third vice-president, Leon L. Solomon, Louisville, Ky.; secretary, Noble P. Barnes, M. D., Washington, D. C.; recorder, William M. Spriggs, M. D., Washington, D. C.; treasurer, John S. McClain, M. D., Washington, D. C.; Curator, Dr. George C. Ober, of Washington. Dr. Leon L. Solomon, of Buffalo, read the final paper of the meeting, "The Therapeutics of Alcohol."

A committee was appointed to investigate the plan of establishing a Bureau of the Materia Medica, with Dr. F. E. Stewart as chairman. A committee was also appointed to investigate the plan of establishing a Psycho-Physical Laboratory under the control of the Department of the Interior. The Society adjourned to meet in New York, the second Tuesday of May, 1902.

Correspondence from Dr. George Elliott, 129 John St., Toronto.

CANADA.

Sir William Hingston, on the occasion of the fortieth anniversary of his entering Hotel Dieu Hospital, Montreal, was the object of a very pleasing demonstration on the 6th inst. Sir William has now reached his seventy-third year, but still continues in the active practice of his profession, and even on that very day had performed two critical opera-

tions at the Hotel Dieu. The ceremonies opened with a religious ceremony. Mass in the chapel of the hospital being celebrated by Archbishop Bruchesi, after which the surgeons of the Hotel Dieu presented Sir William with an address accompanied by an urn of great value. Then the students of Laval University gathered in the operating room, where they presented their esteemed professor with an address and handed Lady Hingston a magnificent bouquet. The sisters of the institution also paid their respects to the distinguished surgeon, and presented him with some relics brought over from France by Mille. Mance over two hundred years ago and since preserved by her successors. The patients of the hospital, too, gathered into one of the wards where Dr. St. Jacques in their name thanked Sir William for the many services he had rendered during the forty years of his service at the Hotel Dieu. Sir William overwhelmed by such praise and thanks expressed some surprise at the latter testimonial when, as he facetiously remarked, he had always been busily engaged taking off their arms and legs or taking out their eyes. However, he thought he had never performed an operation which he did not deem justifiable in the interests of his patients.

The value of a Smallpox Waiver in the case of life assurance has been aptly illustrated in the recent unfortunate death of one of Toronto's physicians. Dr. Thomas Henry Little died on the morning of the 25th of April, at the smallpox hospital, of hemorrhagic smallpox, he having contracted the disease from a very mild case, and at the same time thinking that he was not attending on a case of smallpox at all, but for another ailment, having the patient calling at his office for treatment. Dr. Little was a graduate of Toronto School of Medicine and had been practising in this city for twelve years. He was thirty-nine years of age. He had never been vaccinated, although this was subsequently denied by his friends. It transpires also that he had signed smallpox waivers to the extent of \$11,000 insurance. His sad death also emphasizes the importance of vaccination, viz., in contracting a malignant form from an unsuspected mild form of the disease.

A Slander by one Medical Man Against Another has recently been tried at the non-jury sittings of the High Court on the 6th inst. at the town of Barrie, Ont. Dr. L. H. Campbell, of Bradford, Ont., sued Dr. L. Clement, of the same place, for libel. It appears that the defendant wrote a letter, accusing the plaintiff of want of skill in his profession. The letter was addressed to a friend of Dr. Campbell, in which Dr. Clement offered to put up \$50 to \$100 that if a post mortem were held on a certain case, his charges would be substantiated. At the trial the defendant conducted his own case. He admitted writing the letter and said there was no malice, that his action was in the public interest. He further admitted that his practice had been reduced two-thirds since Dr. Campbell had come to practice in Bradford. Judgement was given for the plaintiff for \$200 with costs, although the Judge remarked he felt tempted to allow the full amount asked for, viz., \$1,000.

The Canadian Nurse, if a report which comes to the Toronto daily press from New York can be relied upon, is evidently holding her own in the United States—and presumably even more than doing so with her American cousin. It is said that Canadian girls constitute one-half of the graduating classes of the leading training schools of New York and all the big cities from the Atlantic Ocean to the Rocky Mountains. The Canadian girl is now said to be prominent in all the professions in the United States, but it is in trained nursing that she has achieved her greatest distinction. The report goes on to say that they are even popular as wives of American doctors. Amongst some of the best known are Miss Russell, a daughter of the medical superintendent of the Hamilton Insane Asylum, who went to Cuba to nurse American soldiers, and who has also been in South Africa; Miss Burdette, superintendent of the lying-in hospital built by Mr. J. Pierpont Morgan; Miss Rykert, who is superintendent of the training school of the Post Graduate Hospital; and Miss Richmond, assistant head nurse at the Kemp Memorial Hospital. Other cities mentioned where these Canadian nurses hold prominent positions are Pittsburg, Chicago, Cleveland, Cincinnati and Buffalo.

The Toronto Branch of the Anti-Consumption League held its annual meeting in this city on the evening of the 5th inst., Dr. E. J. Barrick, the president, in the chair. It was decided that the time was opportune for the sub-

mission of a by-law to the ratepayers for \$50,000 for the purpose of a municipal sanitarium. Last fall the local board of health, acting under the advice of Dr. Sheard, the medical health officer, recommended the submission of such a by-law, and it was at that time that the National Sanitarium Association made an offer to provide accommodation for Toronto's consumptive poor. The report of the secretary, the Rev. Dr. Eby, showed that there were now 600 members of this branch of the league. The treasurer's report showed the receipts to have been \$1,362 and the expenditure \$1,250. A suggestion was made that the city establish a canvass hospital beyond the city limits for the reception this summer of at least a percentage of its hundreds of consumptives. The local branch decided to accept the offer of the Central Association at Ottawa to provide \$700 to send Dr. Eby through Ontario as a special organizer and educator for the next six months.

The Victorian Order of Nurses, Toronto branch, held their annual meeting in this city on the afternoon of April the 27th. Dr. James Thorburn, the president, in the chair. Lady Minto was present from Ottawa, and delivered an address on the work of the Order throughout Canada. She told of the encouragement she was receiving for her cottage hospital scheme for the Northwest Territories. The Dominion Government has given \$6,000 for this work. Sir William MacDonald, Montreal, has donated \$3,000, and contributions to the amount of \$4,000 have been received from other sources. The report of the local superintendent showed that during the past year the Order had cared for 249 cases in Toronto, with 4,323 visits and sixteen deaths. There had been added to the list thirty-eight Toronto physicians, who now employ these nurses. During the year \$472 had been collected in fees.

Samaritan Hospital, Montreal, held its annual meeting last week, when the report of the surgeon-in-chief and superintendent, Dr. A. Laphorn Smith, was presented by himself. During the past year this institution has cared for 110 in-patients with a total number of 2,125 days in the institution. Many were very serious cases and 142 operations had to be performed. Only five deaths occurred, three of which followed operations, which gives a death rate of a trifle over two per cent. There were also 250 out-door patients; and at the present moment all the beds in the hospital are occupied. Dr. Smith stated that this institution only admitted women of irreproachable character, who required medical treatment peculiar to their sex. At the present time there are a large number of suitable young ladies waiting to be trained as nurses, but until such time as a larger building can be provided no increase will be made to the present staff.

The Toronto Clinical Society held its final meeting for the season of 1900-1901 on the evening of May 1st. The year has been a very successful one. Dr. H. A. Bruce presented a patient, a young man of 24 years, upon whom he had operated about seven weeks ago for mastoid disease and in addition to finding pus there also found a large quantity in the temporo-sphenoidal lobe, some three or four ounces. When five years of age this young man had otitis media of the right ear and after treatment for two years was cured. Whenever he contracted a cold, however, a few drops of discharge appeared, but only for a day or so. When taken again two weeks prior to operation, he had slow pulse, depressed temperature, exaggerated knee jerks, ankle clonus, slight vomiting; no unconsciousness. Patient made a good recovery after operation, some slight exaggeration in the knee reflexes and ankle clonus being still present. Dr. F. LeM. Graeet showed a large lipoma removed from the thigh of a woman just above the popliteal space. Considerable difficulty was experienced in separating the great sciatic nerve from the tumor, it being spread out over the posterior aspect of the tumor. Dr. George A. Bingham related the history of an enterprising lad of 14 years, a cripple, who, having heard of the good work being performed for crippled children at the Victoria Hospital for Sick Children, Toronto, and not being possessed of sufficient means to come by train, harnessed his dog to his sleigh and drove all the way to the city, a distance of twenty miles, in the dead of winter. He was very much deformed from his knees down. The lad reaped the reward of ambition. The election of officers took place and resulted as follows: President, Dr. J. F. W. Ross; Vice-President, Dr. E. E. King; Treasurer, Dr. W. H. Pepler; Recording Secretary, Dr. George Elliott; Cor-

responding Secretary, Dr. A. A. Small; Executive Committee, Drs. H. J. Hamilton, H. B. Anderson, W. B. Thistle, H. A. Bruce and George A. Bingham.

The Victoria Asylum for Women, Coburg, Ont., is rapidly nearing completion and the Government expects to open it for the reception of patients by the 1st of September. Dr. McNichol has been appointed medical superintendent and will have associated with him as assistant physician, Dr. Harriet Cockburn, of Toronto, this being the first instance of official recognition of the claims of the lady medicos. Dr. Cockburn has had considerable experience in hospital work, having been connected for some time with the Dakota State Asylum for the Insane. Dr. McNichol has retired from private practice in Coburg and is at present devoting his attention to asylum work in the various institutions of the province.

UNIFORM MEDICAL LEGISLATION.

side of the medical profession, have an idea of the serious problem which must confront them in the near future. The fact that in one state or territory is regarded as unfit to treat people in another political division necessarily invites every intelligent citizen to investigate the reasons for such a state of affairs.

In any country the lives of all citizens should be valued equally high. This is not the case in the United States. Any one who is familiar with the different medical laws in the various states and territories cannot conceal his grievance and indignation that conditions are allowed to exist which reflect upon the intelligence of many, and on the good will of some, in a way so strange to the American mind and so little in accord with the general interest in other public matters.

Either the standing of those physicians is not sufficiently high

education proper.

would be a wise step to close about three-fourths of the schools now existing, and to place the rest under rigid state institutions, as, for example, the University of

Many of the medical schools now existing are the property of corporations for the benefit of a few. Special priv-

which concerns every citizen.

schools in our country to twenty medical schools in Germany.

tioned, besides others, must be considered.

The importance of the movement is recognized more and

and it is to be done with more satisfaction at the point at large interests itself in the same to a greater extent.

A great problem is before the people of the United States. Its solution should not be delayed.

Changes in the Medical Corps of the Navy, week ending May 11, 1901.

ASSISTANT SURGEON J. S. TAYLOR, detached from the Medical Staff to the Naval Hospital, Yokohama, Japan.
ASSISTANT SURGEON F. L. HUNTER, detached from the Naval Hospital, Yokohama, and ordered to duty on the Asiatic Station.
MEDICAL DIRECTOR E. Z. DERR, detached from the Naval Academy, and ordered to duty on the Asiatic Station.
SURGEON F. W. P. WHEELER, detached from the San Juan Naval Station, and ordered to the Naval Academy, May 6th.
SURGEON C. H. T. LOWMEDES, detached from the Lancaster, May 11, and ordered to the San Juan Naval Station via the Mayflower.
P. A. SURGEON E. S. BOBERT, ordered to the Lancaster, May 11th.
SURGEON L. W. CURTIS, detached from the Vermont, May 11th, and ordered home to be in readiness for sea duty.
SURGEON G. PICKRELL, ordered to the Vermont, May 11th.
SURGEON C. F. STOKES, detached from the Asiatic Station, and ordered home, via mail steamer.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, U. S. Marine Hospital Service, during the week ending May 11, 1901.

Appointed Assistant Surgeons.—Acting upon the recommendation of Surgeon-General Wyman of the Marine Hospital Service, the Secretary of the Treasury has appointed the following persons as assistant surgeons, to serve during the quarantine season at the various fruit ports of Central America, their principal duty being that of inspecting fruit to be exported to the United States: Bocos del Toro, Colombia, Paul Osterhout; Port Limon, Costa Rica, D. W. Goodman; Livingston, Guatemala, W. K. Fort; Puerto Cortez, Honduras, S. H. Backus; Ceiba, Honduras, R. H. Peters; Belize, British Honduras, J. Grey Thomas; Bluefields, Nicaragua, W. H. Carson.

MISCELLANY.

Fourth Annual Meeting of the American Gastro-Enterological Association.—The Shoreham, Washington, D. C., May 1st, 1901.—The meeting was called to order by President Einhorn at 10.24 A. M. Paper by Dr. Max Einhorn, "Syphilis of the Liver." The doctor gave a very comprehensive resume of the subject, and said that from the middle ages to the beginning of the seventeenth century great importance was attached to the liver in syphilitic diseases. It was generally believed that syphilitic ulcers were the result of bad humors of the body, the origin of which was to be looked for in the liver. The pathological anatomy and clinical studies were reviewed and a report made of thirty cases, 29 of whom died. He divided syphilis of the liver into three classes—gummata, syphilitic cirrhosis, and syphilitic disease belonging to either of the above-mentioned groups and accompanied with icterus. The first case was that of a patient who had chancre six years previously. He suffered with disturbances of digestion, poor appetite, much belching, loss of weight, etc. With treatment by iodide of sodium and innunctions of mercury the patient finally was cured. Diagnosis of hepatic syphilis can be most positively made in cases in which there exist gummata of the liver, in conjunction with other signs of a present or recent attack of syphilis. Gummata of the liver are easily confounded with malignant neoplasms. The majority of cases have pain in the right hypochondrium, sometimes constantly and sometimes in attacks, occasionally gallstone colic; this is accompanied by disturbances of digestion, and a feeling of tension in the upper half of the abdomen, with loss of weight. In the more advanced stages there is amyloid degeneration. The doctor did not always find enlargement of the spleen. The treatment should consist of anti-luetic measures, iodide of potassium or iodide of sodium and similar preparations of iodine. The hygienic and dietetic elements in a patient's life should not be overlooked.

In discussion, Dr. J. C. Hemmeter said that he was impressed with the very scholarly paper and that its value chiefly consisted in the collated literature brought before the society in one article.

Dr. Edward Quintard mentioned a case of a tumor as large as a small fist, in which the polymorphonuclear neutrophils were absent and asked the essayist whether any note was made of that particular count. He concurred in the combination treatment of iodide of potassium and the ointments mentioned.

Dr. John A. Lichty commended the essayist on the use of iodides and anti-syphilitic treatment, especially in cases where there is a marked condition, and believed that after all one would be obliged to fall back upon the therapeutic test.

Dr. J. C. Hemmeter, speaking again, said that he recollected three cases of syphilis of the liver that occurred in his experience. One was that of a man who was supposed to have tuberculosis of the lung, but the autopsy proved it to be a gumma of the lung which had pulled apart the bronchial tube.

Paper by Dr. J. C. Hemmeter, "The German Clinics of To-Day." The doctor said that "modern therapeutists are not satisfied to study the diseased process and its course, the physician must also familiarize himself with the special manner in which disease manifests itself in and influences the individuality of each and every patient. The personality of every patient is put in the foreground of treatment, not the conception of the disease. This is one of the predominant features of the therapeutists in German clinics of to-day." After reviewing the different contributions of Continental experimentors, he made a plea for the establishment of a journal on diet and physical medical treatment, which should be the offspring of the Society, in which could appear the investigations and clinical, experimental and pathological observations concerning the treatment of disease by dietetic means, that such a journal is a necessity.

Dr. Quintard said, in speaking of the new journal: "It is necessary for the majority of American physicians and I think the suggestion is really particularly timely."

Dr. Einhorn said that one must appreciate not only the necessity for studying scientific methods, but of practically helping the patient, and the giving of proper sunshine, correct diet and good nursing.

Dr. Aaron expressed himself in favor of the establishment of the proposed journal of dietetics and hygiene.

The following papers were read by title in the absence of their authors: "Etiology of Hepatic Sclerosis," Dr. A. L. Benedict; "Treatment of Gastric Ulcer," Dr. D. D. Stewart; "The State of the Gastric Secretion in Chronic Rheumatism and Rheumatoid Arthritis," Dr. Frank H. Murdoch.

Paper by Dr. Edward Quintard on "Spastic Ileus." The author believed that spastic ileus is of much more common occurrence than is generally recognized and he reported a number of cases in which he gave not only the similarity which existed between spastic ileus and mechanical ileus, but also gave the methods of differential diagnosis. As to the theory of the causes of fecal vomiting there was a sketch given from the time of Galen to that of the Haguënot theory and the theories of the present day.

In discussion Dr. Quintard reported two of his own cases, in neither of which had there been the fecal vomiting which had been observed in many other cases. He held that there was such a thing as pathological antiperistalsis. The author cited several cases which proved almost conclusively that such was the case, and although he believed that the Haguënot theory explained many of the cases of fecal vomiting in mechanical ileus, he also held that in spastic ileus the theory of antiperistalsis came very nearly covering the point.

Dr. Rose spoke of the desirability of the pathological condition of the splanchnic nerves being better understood. He proposed the treatment of warm water and opiates, also the application of carbonic acid gas—the inflation of the rectum with this gas. With him this last named treatment had been effective in cases of dysentery and peritussis in children.

Paper by Dr. Wm. Gerry Morgan, "Some Cases of Tetany." He defined tetany as an affection characterized by the occurrence of, for the most part, tonic, but occasionally clonic, spasms in the hands, forearms, feet, legs, and, in severe cases, the neck, face, larynx and trunk. The doctor thoroughly explained the etiological factors and spoke of the dehydration theory of Kausmaal. The opportunities for pathological study have been very few. Prognosis in tetany depends upon the particular disease with which the condition is associated and upon the nature of the attack.

The doctor made a fine distinction between epilepsy and gastric tetany and related many interesting cases.

In discussion, Dr. Rose said that in English literature one would find a great many cases of tetany in connection with acute dilatation of the stomach. He spoke of the compensating element as analogous to that in heart disease. Further discussion was prevented by the usual midday adjournment.

Afternoon Session.—Paper by Dr. Julius Friedenwald, "The Report of Two Cases of Acute Dilatation of the Stomach." The doctor believed that the symptoms of the disease are so clearly established that diagnosis can usually be made without difficulty. Much attention has been paid to chronic dilatation, while little has been said concerning the acute form, which is probably due to the fact that it occurs with much less frequency. Dilatation may be caused by serious infectious diseases and sudden overloading of the stomach or improper diet. Many cases of acute dilatation were reported with fatal results, the necropsy affording an opportunity to note the pathological conditions. In one case lavage and the use of the stomach-pump proved of great value. The etiology of the acute form is somewhat obscure, except as previously mentioned, through gross errors in diet and overloading. Pepper and Stengel were quoted as suggesting the immediate cause, being spasm of the pylorus. It is well to remember the possibility of the occurrence of acute dilatation in all cases of acute dyspepsia and quickly to empty the stomach either by means of some brisk emetic or by means of the stomach tube.

Dr. Hemmeter referred to the great obscurity of the pathogenesis of these acute dilatations. He related a case in consultation in which a patient was operated for gallstone and the surgeon had an opportunity of seeing the stomach and said that it was normal and in its proper position, but looked rather small. Test meals had been taken and everything seemed to be normal. The day after the operation the patient died from symptoms of ileus and at the autopsy an enormously distended stomach was found.

Dr. Einhorn said that these cases should be termed acute dilatation, and that in order to make that positive, it would be necessary to observe such patients for quite a while after and see if they had any return. He mentioned certain cases of beginning obstruction of the pylorus, with no noticeable symptoms until suddenly an abrupt awakening.

Dr. Quintard referred to Dr. H—— who took the \$100 prize in the Philadelphia Medical Journal on the "Size and Location of the Stomach."

Dr. Julius Friedenwald closed the discussion by saying that there were but few authentic cases of dilatation of the stomach, a great many being spoken of as gastric atony.

In the absence of their authors the following papers were read by title: "Experiments in Peristalsis," Dr. Fenton B. Turck; "Some Clinical Studies in Gastric Secretion," Dr. G. W. McCaskey; "Report of a Case of Cancer of the Cardiac End of the Esophagus at a Distance of Twenty-one Inches from the Incisor Teeth in a Man Five Feet and Three Inches Tall," Dr. C. D. Spivak.

Paper by Dr. A. Rose, "Treatment of Atonia Gastrica and Splanchnoptosis by means of Abdominal Strapping." Dr. Rose cut from a newspaper the size and kind of bandage that he specially recommends. His paper proved to be a very exhaustive treatise on the subject. He believed that a number of pathological conditions of the stomach are caused by insufficient activity of its muscular fibres, diminished activity of its walls, elongation of the suspending ligament of the lesser curvature, the lesser omentum and gastropotosis. The doctor said he uses the term "gastropotosis" instead of "gastropotosis," as formerly. He was of the opinion that gastropotosis is very frequently present in phthisical patients and rare in strong and robust people, except when caused by trauma or by peritonitic adhesion. It may be caused by hernia; also tumors of the spleen and liver and enlargement of the abdominal space. Tight lacing and the tight attachment of skirt strings aggravate an existing gastropotosis. He spoke of an interesting examination of one hundred patients in order to establish the significance of the phenomenon of the splashing sound of the stomach. Men afflicted with the condition present symptoms of general nervous irritability less often than women. Discussion was spirited on the subject of supporting the abdomen by strap or bandage. Dr. Lichty said he was disappointed in the bandage. Dr. Hemmeter said that the bandage as described by Dr. Rose seems to have the

advantage of grasping the whole abdomen. Dr. Aaron asked whether the secretions would not soften the bandage and thus shorten its life. Dr. Lincoln reported that by his method of application he secured support for five weeks.

Dr. Einhorn said that strapping would not do as much for the patient as the bandage.

Paper by Dr. John A. Lichty, "Hyperchlorhydria." The doctor said that about one-third to one-half of the patients suffering from digestive disturbances have hyperacidity. Among 225 consecutive cases whose stomach contents were analyzed 84 or about one-third had more than the normal amount of acid. The patient suffering from hyperchlorhydria proper usually gives no history of indiscretion of diet. He believed that the splanchnoptosis is the result of the starvation diet to which the patients are driven. Electricity should be applied percutaneously. The doctor had not found any advantage in the intragastric electrode in these cases.

Dr. Hemmeter reviewed some interesting experiments, on two fox terriers, one of which was fed on the proteids and the other was fed on soup meat, etc. Dr. Friedenwald favored internal electricity.

ELECTION OF OFFICERS.

President, Dr. John C. Hemmeter, Baltimore; First Vice President, Dr. W. D. Booker, Baltimore; Second Vice President, Dr. S. J. Meltzer, New York; Secretary and Treasurer, Dr. Charles D. Aaron.

Dr. Max Einhorn was elected as a member of Council to serve for three years.

(Adjourned.)

The American Association of Genito-Urinary Surgeons.—Held at the Hotel Chamberlin, Old Point Comfort, Va., April 30, May 1 and 2, 1901. The President, Samuel Alexander, M. D., of New York, in the chair.

Address by the President, Dr. Samuel Alexander, M. D., of New York, called the attention of the Association to the death of one of its former Presidents, Dr. Fessenden F. Otis. He then considered the subject "The Treatment of Intra-peritoneal Traumatic Rupture of the Bladder by Laparotomy and Suture." He reported 45 cases with 23 deaths and 22 recoveries, and considered the following questions: How can we prevent delay in operating upon these cases? How shall we treat the abdominal cavity to obtain the most thorough asepsis? How shall we most effectually close the bladder wound?

Report of a Case of Nephrectomy for Adeno-Carcinoma with Remarks on Combined Cystoscopy and Segregation as a guide to the Earlier Surgical Intervention.—Dr. John P. Bryson, of St. Louis, read a paper with this title. He said that the matter of the relative excretion of the urea may have been too much overlooked but we cannot tell how well a kidney may be doing until we know what the blood brings to it and the antecedents or urea in the blood are, so far as we know, influenced by so many conditions that it is difficult to bring it within a working formula. Cystoscopy may be of service in this matter, but the phloridzine test appeared to have the greater value. He thought it would be but a one-sided pathology and too narrow specialism which would fail to take into account the relationship of the condition and functional activity of other important organs as their changes affect the kidney and its work.

The value of the X-Ray in the Diagnosis of Renal Stone: Report of Four Cases.—Dr. Paul Thorndike, of Boston, briefly reported these cases not in order to show beautiful X-ray plates of kidneys containing calculi, but because the cases were studied by the same people under the same conditions and show results, partly negative in character, which the writer deemed of enough interest to justify presentation. It seemed to be true that stones which contain mineral salts are much more readily photographed than others, and yet, in two of the cases presented, where the stones were made up of layers of uric acid and in both distinct shadows were evident, while in one of them the stones were shown with considerable clearness, probably due to the admixture of urates in the former and of calcic phosphate in the latter case.

Rupture of the Urethra: A Report of Cases.—Dr. James R. Hayden, of New York, read a report of three cases, giving the detailed histories of them, describing the operation and giving the results of treatment.

Inversion of the Tunica Vaginalis for Hydrocele.—Dr. Robert H. Greene, of New York, read a paper with this title, in which he made the following conclusions: (1) That

this is an easy operation to perform, and that it results in the cure of the hydrocele seems undoubtedly true. (2) The fact of so many operations having been recorded with the history of no unfavorable result as regards suppuration or neuralgia of the testicle offers pretty conclusive evidence as to the safety of this operation from the above complications. (3) The effect it may have in causing atrophy of the testicle or changes in the function of that organ is a subject concerning which clinical data, extending over a long period of time, are necessary before final conclusions can be drawn.

A Case of Unusual Bacillus of Abnormally Behaving Gonococcus.—Dr. J. P. Tuttle, of New York, described such a case, in which the behavior of the coccus found was entirely different from that of the gonococcus in that it was rapidly destroyed in all acid media, but in an alkaline media it rapidly thrived. The case finally resolved itself into a very obscure form of syphilis, and, under the influence of mercury, the urinary symptoms gradually cleared up.

Partial excision of the Bladder and Urethra for Carcinoma.—Dr. Tuttle reported this case of cancer of the rectum which involved the urethra, the prostate and possibly the wall of the bladder.

SECOND DAY, MAY 1, 1901.

Some Unusual Manifestations of Syphilis (Clinical and Pathological Illustrations).—Dr. John A. Fordyce, of New York, considered gangrene of the initial lesion, lichen planus and syphilis, syphilis and pemphigus, syphilis and psoriasis, syphilis and lepra and syphilis and lupus. These were accompanied by illustrations.

A Case of Prostatectomy.—Dr. James Bell, of Montreal, read a report of such a case showing the peculiar enlargement of the prostate, and the fact that the Bottini incisions could not have effected this enlargement.

What I Have Learned From One Hundred and Sixty-one Operation for the Relief of Senile Hypertrophy of the Prostate Gland.—Dr. Orville Horwitz, of Philadelphia, read a very long and complete paper on this subject, considering the subject under the sub-headings of vasectomy, castration, supra-pubic cystotomy, prostatectomy and the Bottini operation. His conclusions in brief were as follows: 1. Success following the Bottini operation depends on having perfect instruments, a good battery, the necessary skill, and the employment of a perfect technique. 2. In suitable cases the Bottini operation is the safest and best for the radical cure thus far devised for the relief of prostatic hypertrophy. 3. It is often very efficacious in advanced cases of obstruction as a palliative measure, rendering catheterism easy and painless, relieving spasm, lessening the tendency to constipation, and improving the general health. 4. It is of special service in the beginning of obstructive symptoms due to hypertrophy of the prostate gland, and may be regarded as a means of preventing catheter life. 5. It is indicated in all forms of hypertrophy except where there is a valve formation, or where there is an enormous growth of the three lobes, associated with tumor formation giving rise to a pouch, both above and below the prostate gland. 6. Where the bladder is hopelessly damaged, together with a general atheromatous condition of the blood-vessels, associated with polyuria, results are negative. 7. Pyelitis is not a contra-indication. 8. The character of the prostatic growth has no bearing on the results of operation.

Some of the Conditions Following the Bottini Operation for Prostatic Obstruction.—Dr. L. Bolton Bangs, of New York, brought out the following points, which he considered of importance: 1. The muscular impediment which almost immediately follows the removal of the instrument. 2. The process of repair, as witnessed by the cystoscope, which begins and proceeds as in ordinary aseptic wounds. 3. The decided necessity for after-treatment because patients that come to us usually suffer from a chronic catarrhal condition of the prostate, seminal vesicles, bladder and urethra.

Contracture of the Neck of the Bladder.—Dr. Charles H. Chetwood, of New York, after considering the causes and symptoms, referred to the treatment, as advocated by him, and which was a modified Bottini operation. He used a specially constructed instrument which performed the same function as the galvano-cautery knife of Bottini which operates through a perineal opening. He then described the instrument and the technique of operating. 16 cases were reported. The ages were between 30 and 73 years, 6 being under 45 and the remainder between 45 and 73.

Out of this number there was one death, which occurred five weeks after the operation from a pyelonephritis. He stated that if a perineal opening was made many cases of the contracture type of prostatic hypertrophy would be recognized, and many would be found suitable cases for the use of the perineal prostotomy with the galvanocautery. The perineal incision permits of exploration, which is better and more rapid than the cystoscope.

Officers Elected for the Ensuing Year:—President, Dr. W. T. Belfield, of Chicago; vice-president, Dr. Paul Thorndike, of Boston; secretary, Dr. James R. Hayden, of New York. Member of Council, Dr. William K. Otis, of New York. Place of meeting, Atlantic City, N. J.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

(Continued.)

M. Allen Starr, of New York, read a paper entitled the **toxic origin of neurasthenia and melancholia**. Cases of toxic neurasthenia are found in poorly nourished women and in men, about 45 years of age, who are negligent of diet and exercise and who are free livers. These patients complain of pain in the head and back, irritability, disorders of circulation and digestion. The urine was irregular in quantity and always contained a large amount of indican. The symptoms of depression are at their height at about 4 o'clock A. M., they gradually disappear until noon, when the patient feels at his best, and they gradually return during the afternoon and night. This train of symptoms, worse in the morning, is not due to the wear and tear of exhaustion, but is more probably due to the action of some intoxicant, which accumulates during sleep, and by its irritation wakens the patient. Although indican is found in the urine, it is probably not the cause of the symptoms. In the treatment of the condition the diet should be nourishing, and of the best form that the patient can assimilate. Fluids should be given in great excess. Digestion should be aided by drugs which stimulate the liver, such as calomel, podophyllin and Carlsbad salt and by the intestinal antiseptics which may act in counteracting the toxic agent. The author uses 3 forms of intestinal antiseptic medication; (1) a capsule of 5 grains of sulphocarbonate of sodium, with one grain of potassium permanganate; (2) a capsule of 5 grains of salol and one minim of castor oil; (3) a capsule of 2 grains of benzoate of sodium, and one grain each of sulphocarbonate of zinc and naphthol. These capsules are coated with shellac to prevent them from becoming dissolved before they reach the intestine. Baths, exercise and rest form an important part of the treatment.

W. W. Johnston, of Washington, showed the patient suffering from **Addison's disease** that he exhibited to the association last year. The improvement continues under treatment with suprarenal extract, the patient lives on a farm and does heavy farm work. He has gained 2 pounds in weight.

Johnston read a paper entitled, **the evils arising from failure to recognize the true nature of neurasthenia and some of the causes of this failure**. The reader referred to the case of Charles Darwin, who, from the affects of fatigue, hardship and strain, was a neurasthenic when he returned to England from his voyage in the *Beagle*. Darwin found that his sufferings were much relieved by rest, and if he had abandoned all work as soon as he returned to England, he might have recovered from his neurasthenia and saved himself much later suffering and misery. When a diagnosis of neurasthenia is made the patient should be required to take a complete rest. Many cases of this affection are curable, but others, of course, are incurable. Devoting attention to gastrointestinal symptoms, or to the symptoms of any one system in the body is a hindrance to final recovery, for as the neurasthenic symptoms disappear from one system they appear in another. The reader was of the opinion that there should be more sanatoria in this country devoted to the treatment of this disease. Cabot, of Boston, said that calomel and podophyllin are not hepatic stimulants, and that ox-bile was the only true cholagogue. He thinks that the term hepatic stimulant should be divorced from such drugs as mentioned. James J. Putnam, of Boston, thought that Starr had not proved his case concerning the toxic origin of neurasthenia.

The daily fluctuation of symptoms is seen in other forms of the disease than the so-called toxic form. Because one has found a remedy it does not follow that the cause of a disease has been found. He is in thorough accord with the suggestion to provide sanatoria for the treatment of the condition. C. A. Herter, of New York, said that there was a relation between intestinal putrefaction and melancholia. In melancholia the ethereal sulphates, which are the best indicators of intestinal putrefaction, are increased. Indol produces irritability of the nervous system and, later, depression. Calomel probably acts in such cases by reducing the absorption of ethereal sulphates. Baumgarten said that it is difficult to assign mental fatigue to its proper cause. The mental worker does not always feel the effect of his overwork immediately. Daily habitual overwork may indeed stimulate the patient until neurasthenia finally develops.

C. A. Herter, of New York, read a paper entitled the **acid intoxication of diabetes and its relation to prognosis**. In normal urine, the total of acid and base almost coincide, with slight excess of acid. In diabetes there is an apparent excess of base, the acid excreted not being sufficient to neutralize the bases excreted. When the method of estimating the total amounts of acids and bases cannot be carried out in detail an approximate result can be obtained by estimating the nitrogen of ammonia. In cases of diabetes with impending coma the nitrogen of ammonia will be increased. In cases of diabetes, the urines of which were examined, there was increase in the excretion of organic acids, estimated in terms of oxybutyric acid, and also of the nitrogen of ammonia during coma and in impending coma. In the case of a patient who was on a moderately restricted diet the amount of organic acid excreted was high and the excretion of potassium was almost as much as that of sodium. Under strict exclusion of carbohydrates for 4 days, the amount of acid excreted decreased and the potassium excreted decreased and returned to its normal relation to the sodium excreted, about 1 to 2. In cases of diabetes in which urine does not contain an excess of organic acids the progress of the case is usually satisfactory. The relation between the sugar excreted and the amount of organic acid in the urine is not constant; the sugar may drop and the acid continue high or *vice versa*. As a rule, when large quantities of sugar are present in the urine the organic acids are also present in large amount. The estimation of the nitrogen of ammonia is useful for clinical purposes, because, as a rule, considerable oxybutyric acid is attended by an increase of the nitrogen of ammonia. The latter factor, however, cannot be relied upon in the estimation of the output of small amounts of oxybutyric acid. There is danger of coma whenever the amount of oxybutyric acid is high; but the nitrogen of ammonia may be increased to 17% and coma be delayed. A patient may feel well and be able to do a considerable amount of muscular work even when he is excreting 30 mg. of oxybutyric acid daily. A patient whose urine contains no organic acid is in no immediate danger of coma, but he is liable to the other accidents of diabetes.

E. P. Joslin read a paper entitled **metabolism in diabetic coma with special reference to acid intoxication**. The author referred to a case of diabetes which was under treatment for 2 years and 2 months. During this time the patient gained in weight. Diacetic acid was absent from the urine when the patient was first seen; it then made its appearance and remained for 2 years; it then disappeared and remained absent until death occurred. The relation of organic acid to nitrogen was high. Victor C. Vaughan, of Ann Arbor, said that the substance producing acid intoxication is not known, or else the admixture of alkalies would result in cure. He believes that death is hastened by excessive nitrogen metabolism, because acid substances arise from nitrogenous food and coma may be prevented by reducing the amount of that kind of food administered. He is inclined to believe that the elimination of potassium indicates a disintegration of the body cells. C. A. Herter, of New York, said that the amount of acid produced in cases of diabetes is so large that the alkali administered can neutralize only a portion of it. He believes that acid is the cause of the condition, although the nature of the acid is not known. His studies, however, point to oxybutyric acid as the offending substance. He agrees that the acid is derived from the nitrogenous food, and he thinks that the ammonia also comes from meat diet. Franz Pfaff,

of Boston, said that the administration of fat increases the amount of acetone in the urine.

J. George Adami, of Montreal, read a paper entitled **classification of the intoxications from a pathological point of view**. The author divides the intoxications into (1) exogenous, due to poisons introduced from without and (2) endogenous, due to poisons elaborated within the body. The exogenous intoxications may be (1) exotic, if introduced through the skin or through the mucous membrane of the respiratory or digestive tracts, and (2) indigenous or excretory, due to reabsorption of secretions, indirect auto-intoxication, or disintegration processes. The endogenous intoxications may be (1) direct auto-intoxications due to internal secretions discharged from the cells or to disintegrative processes of the cells and (2) parasitic, which may in turn be microparasitic or macroparasitic.

[J. M. S.]

First Day, Evening.—The evening session was occupied by demonstrations of photographs with the stereopticon, gross morbid anatomy specimens and microscopic specimens of various pathological conditions. Charles Bond, of Richmond, Indiana, showed with the stereopticon, specimens of **photomicrography**, some of which represented work at a magnification of 3,000 diameters.

William F. Councilman, of Boston, showed a series of photomicrographs with the stereopticon representing the lesions of the kidney in cases of diphtheria.

H. C. Ernst, of Boston, showed a series of photomicrographs with the stereopticon showing various pathological conditions.

Simon Flexner, and R. M. Pearce, of Philadelphia, exhibited a collection of gross specimens illustrative of the lesions of **experimental acute pancreatitis in the dog**.

William H. Welch and Eugene L. Opie, of Baltimore, exhibited specimens that illustrated **hemorrhagic pancreatitis, both human and experimental** and a specimen of **filarial lymph-varix**.

William H. Welch, W. G. MacCallum and Buckley, of Baltimore, exhibited specimens of **multiple myelomata** and of **epizootic hemorrhagic encephalitis**.

(To be Continued.)

NINETEENTH GERMAN CONGRESS FOR INTERNAL MEDICINE.

(Continued.)

2D SESSION.—V. Struempell of Erlangen in the chair. The second session was devoted principally to a discussion of the papers read at the first session. Schott of Mannheim considered the strengthening of the heart itself of prime importance, the effect on the vasomotors secondary; a more powerful systole acts at the same time as a stimulant to the vasomotor nerves. The effect of the heart stimulants is largely dependent upon the concentration and mode of application, especially in the case of camphor. Jacob of Cudowa confirmed the statement that digitalis has no effect in lesions of the aortic valves, and explained this failure of the drug by the fact that the heart is already performing the utmost possible amount of work; a stimulant cannot, therefore, increase the heart action. Lang of Marienbad called attention to the poor and varying preparations of digitalis as the cause of varying action of the drug. This is especially the case with the infusions. The action of the drug can often be increased by combining it with other stimulants, especially alcohol. Heintz of Erlangen remarked that the finely powdered drug often gives much better results than a coarsely powdered preparation. Goldscheider of Berlin warmly recommended the use of 0.1-0.2 gr. digitalis *pro die* for months at a time, in cases with a tendency to frequent recidivation. Goldscheider recommended the gradual discontinuing of the drug, gradually decreasing the dose for weeks. He believes that one can obtain more exact results with digitoxin. Hirsch of Leipzig described the experiments made by himself and Beck on the determination of the viscosity of the blood. The viscosity of the blood is not due to the corpuscles alone, but also due to the composition of the blood serum. He has found that it is to some degree dependent upon the nutrition of the animal. He found that no proportion existed between

the specific weight and the viscosity of the blood. Ewald of Berlin emphasized the necessity of removing the pressure of exudations and transudations upon the walls of the blood vessels, and demonstrated an apparatus devised by Dehio of Dorpat to aid in the sacrifice of edema. Ewald pointed out further that digitalis can cause digestive disturbances, even when given in the form of a clysm, or in a suppository, and considered the anorexia due to the influence of the drug upon the nervous centre. Friedel Pick of Prague mentioned the action of digitalis in lessening edema by the contractile effect of the drug on the blood vessels. Hydrastin acts advantageously in the same way. Unverricht of Magdeburg noted the poor quality of many digitalis preparations. He judges the effect of a given preparation from the amount of digitoxin it contains. Unverricht recommended the dialysates prepared by Golaz, which contain constant quantities of the glucoside. He considers digitoxin better than any of the other digitalis preparations. The speaker considered the continued use of the drug to be disadvantageous, on account of the cumulative action of the drug and the further results—digitalism and anorexia—which latter he has also been following the use of the drug *per rectum*, and which he also considers of central origin. Rosenstein of Leiden praised strophanthus, which he uses almost exclusively in his clinic, and which he prefers because strophanthus causes no stomach disturbances. The French clinicians use the drug extensively. Camphor, because of its transitory action, should be confined to cases of immediate danger, but in such cases should be used more frequently than it is. In regard to the viscosity of the blood Rosenstein mentions the view long held by English authors that anemic murmurs are caused by a changed composition of the blood. He does not believe in the idea suggested by Hirsch that a change in the viscosity of the blood can cause hypertrophy of the ventricles. Naunyn of Strassburg considers the old *infusum digitalis* the most valuable preparation. His experiments with digitoxin were negative. He does not believe in the cumulative action of digitalis nor in the bad effects on the stomach. He uses the drug in long continued small doses. Grodel of Bad Nauheim has never seen digitalism, either in a form similar to morphinism, or that his patients ceased to react to the drug. He does not believe that the drug lengthens the patient's life, but that it does make their last years more comfortable. Of course one must sometime change the drugs, or cease giving it, according to the conditions. Rosenfeld of Stuttgart has returned to the infusion, having obtained no results with digitoxin. He thinks this due to the fact that the latter is prepared from the stems as well as the leaves, and the stems contain varying amounts of the active principle. In order to retain the good effects of digitalis Rosenfeld recommends the use of *adonis vernalis* as a tea, a tablespoonful to a cup of water, 1-2 daily. Schreiber of Goettingen discussed the value of the determination of the viscosity of the blood. Baeltz of Tokio, Japan, recommended the use of digitalis *infusum*. Next to digitalis ranks strophanthus, which is of especial value if one wishes to attain results in a short time. Baeltz also recommends *adonis vernalis* in the form of tea as a substitute for digitalis. He does not consider digitalism rare. Pranke of Munich suggested that investigators direct their attention more to the action of drugs on the normal organism before directing taking up pathological conditions. Ott of Prague called attention to the difference in digitalis gathered in different parts of the same country, and to the action of carbonic acid on the heart. Gottlieb confirmed Ott's statement in regard to the different toxic effects of preparations of different origin. The physician should know not only how much he prescribes, but also the toxic equivalent of the prescription. Sahli repeated that there is no difference in principle between any of the digitalis preparations. He uses strophanthus often, but the preparations vary considerably. The best preparation is the French strophanthin in the form of pills. Sahli has experienced disturbances in the digestive tract following the use of strophanthus, especially diarrhea. He has seen

good results with digitoxin, but it often has little effect, possibly because it acts too strongly on the blood vessels. He warns against proclaiming it as a complete substitute for digitalis. Smith of Schloss Marbach; "The Examination of the Function of the Heart and some Facts Derived Therefrom," claims to have found dilatation of the heart to be an etiological factor in certain forms of neurasthenia, melancholy, hypochondria, etc., etc., after curing the heart trouble Smith's patients recovered, or at least were improved.

Hoffman of Schloss Marbach; "The Objective Effect of Modern Internal Heart Stimulants on the Heart Function."

Schott of Mannheim; "The Pulse Tension in the Treatment of Chronic Heart Disease." Schott finds by means of Gartner's tonometer that his balneological-gymnastic treatment is followed in certain cases by an increased pulse tension; in these cases his method is indicated. In certain other cases, as in the advanced stages of arterio-sclerosis or myocarditis, and in aneurism of the heart or the aorta, the pulse tension is lessened and the treatment is contraindicated.

GREAT BRITAIN.

Divers' Diseases and Perils.—The *London Globe* quotes: The latest report on the health of the navy contains some important remarks on the accidents and diseases caused by diving operations, contributed by Surgeon Henry N. Stephens, Royal Navy. The diving operations in his Majesty's navy are carried out by men who received a special training in this branch at one of the three gunnery establishments. The principal causes of rejection are (1) tobacco heart; (2) alcoholic subjects are rejected on the slightest suspicion; (3) degeneration of the blood vessels. Bull-necked men are rejected if over thirty-five years of age on account of their tendency to apoplexy, and men are rejected who suffer from nervousness. In the novice the effects of diving may be classed under two headings, namely, (1) hunger, (2) sleepiness. In the first place, the digestive functions are stimulated by one or a combination of the following causes: (a) Owing to the increased pressure of air while diving, there is probably an increased metabolism in the body, nature calling attention to this by an increased appetite. It is proved by the following case that the blood becomes hyperoxygenated by inhaling compressed air while diving; (b) the lightness of the man's breakfast may also partially account for his hunger. Secondly, sleepiness, which is induced after diving may be (1) produced by reaction after excitement; or (2) may be an effort of nature to make up for increased metabolism; or (3) the after effects of congestion of the blood vessels of the brain. Suffocation may be caused by defective apparatus, injury to the air pipe, or insufficient knowledge of the diving apparatus. Fainting or loss of consciousness is of frequent occurrence, and, when the diver is a beginner, is attributed to nervousness. This is often entirely unknown to the diver (the loss of consciousness). The officer instructing divers in this establishment describes it thus: The man is signaled to and asked if he is all right, and he does not reply. He is then signaled to come up and still there is no reply; then he is pulled up to the surface, when he often regains consciousness and strikes out to get hold of the ladder. The man when questioned about it says he did not notice the signals, or that he does not remember anything about it. The signals are good heavy pulls on the breast rope. When a man goes under the surface of the water his body is subjected to considerable pressure in proportion to depth, varying from eight and a quarter pounds to the square inch at twenty feet depth to sixty-five and a half pounds to the square inch at 150 feet depth. In conclusion, Surgeon Stephens recommends that no man should go down after a heavy meal, probably two hours after a light breakfast being the best time. No man should ascend or descend more quickly than one foot per second in shallow water, that is, under five fathoms, and in deeper water one foot in five seconds, with frequent stoppages to allow the ears to be eased and the body to accommodate itself to the altered pressure. He should take about fifteen minutes to descend twelve fathoms, including stoppages. No man should be allowed to stay at a depth of fifteen fathoms for

longer than one hour at a time without coming to the surface.

The Registration of Plumbers.—The *British Medical Journal* states that at a meeting of representatives of district councils for the National Registration of Plumbers, held at London, on April 24th, it was reported that since the conference of Health and Water Authorities and Plumbers, held in Birmingham in October last, 2,082 operative plumbers and 494 master plumbers have been registered, and that numerous applications for registration remained to be dealt with. On the motion of Dr. Alfred Hill, Medical Officer of Health, Birmingham, it was resolved that apprenticeship should be encouraged in connection with the National Registration of Plumbers.

King Edward has made Sir William Henry Broadbent, M. D., a Knight Commander of the Royal Victorian Order, and Dr. A. R. Manley, who has been for many years surgeon apothecary to the Prince of Wales, a member of the fourth class of the same order.

CONTINENTAL EUROPE.

Valuable Discovery.—The well-known Austrian scientists, Professor Loeffler and Dr. Uhlenbuth, announce that they have discovered serum which will protect animals against the foot and mouth disease. This serum affords to animals inoculated with it immunity for from four to eight weeks against infection from the disease. As soon as Drs. Loeffler and Uhlenbuth receive the authorization of their Government the new remedy will be placed at the disposal of the public.

The Military Step.—Dr. Colin, of the French Army, has published (*La Salud*, January, 1901) the results of his investigations regarding the effects which the regulation military step of the disciplined soldier produces on his health and on his constitution. The regularity of the military step causes an indefinite repetition of the shock affecting the bones and the brain which is much more prejudicial than that produced by an irregular walk. Dr. Colin attributes to the regular and uniform repetition of this shock on the same parts of the body much of the pains and diseases peculiar to the soldier. During the march of a single day this shock is repeated 40,000 times, and the strongest men, who can walk a long distance without fatigue when using the ordinary step, yield to the tension caused by the military step after two or three days. Dr. Colin proposes that the heel of the military shoe be made of rubber. The French infantry have begun to adopt this kind of heel, and it seems to afford some relief to the soldier. The Government still continues to experiment with the rubber heels.

Prof. A. von Eiselberg, a pupil and assistant of Billroth and now professor at Koenigsberg, has been appointed to the chair of surgery at Vienna made vacant by the death of Professor Albert.

Hypnotism in Hungary.—On account of the number of crimes committed of late in Hungary, which have been attributed to hypnotic influence, the Hungarian government has prohibited the practice of hypnotism except by medical men and under special permission.

Death of Bizzozero.—The illustrious Italian Pathologist, Giulio Bizzozero, died on April 8, aged 56. His illustrious achievements in histology and biology are well known. He was an untiring and conscientious worker and has contributed many valuable articles embracing original research, to medical literature.

Professor Brouardel, the Dean of the Paris Faculty of Medicine, will not permit his name to be considered for re-election when his term expires in 1902. He has been Dean of the Medical Faculty for 15 years now.

Dr. Lannelongue, Professor of Surgery in Paris, Surgeon to the *Hôpital des Enfants Malades*, has received a médallion, his portrait engraved by Chaplain, from his former students, for his services during the last International Medical Congress.

Professor Rudolph Virchow will attain his 80th year on October 13th, and preparations are being made to celebrate the occasion in a manner commensurate to his position in the scientific world.

Women Physicians of Switzerland have succeeded in having a new hospital exclusively for women, opened in Zurich. The plant costs about 500,000 francs. The physicians are

exclusively women, and a training school for nurses is connected with the institution.

Correction.—We beg leave to call attention to an omission which occurred in the *Philadelphia Medical Journal* of April 13, 1901, in the article entitled "Ligation of the Carotid as a Preliminary Operation to Resection of the Superior Maxilla," namely that the article constituted the advanced sheets of the *Beitraege zur Klinischen Chirurgie* which were sent by the courtesy of Prof. Bruns, the editor.

Lepers in Russia.—According to statistics there are 862 lepers near the Baltic Sea.

A New Veterinary Bacteriological Laboratory.—An institute is being established in Moscow for the purpose of studying infectious diseases in animals.

A Kind-hearted Physician Dies a Pauper.—A well-known physician died recently in Kharkow who devoted his life to the poor. He gave them not only free medical advice, but the greater part of his earnings. He was buried by the police.

An Over-supply of Medical Journals.—The epidemic of medical journalism is invading even Russia. A number of medical journals general, as well as special, made their appearance within the last year. Referring to one of them, the *Medicinskoie Obozrenie* remarks that such a rapid growth, which is out of all proportion to the demand, not only endangers the life of the journals already existing, but tends to lower the standard.

A New Laboratory for the Study of the Plague.—An extensive and costly laboratory is being established in Kronstadt for the purpose of studying the plague, as well as for preparing serum.

American Treatment of Appendicitis.—Prof. Eichhorst calls the operative treatment of appendicitis the "American" treatment. That the Americans may not be so far from right in their treatment has just been evidenced in Prof. Eichhorst's own clinic, where a case of pulmonary gangrene has developed from an appendicitis treated by "passive therapy." The case is: A boy of 13 years was brought into the hospital on March 23, suffering with appendicitis. Treated with opium and cataplasms, the attack passed off. But on April 17, the boy began to cough up the typical sputum of pulmonary gangrene, and now the lower lobe of the right lung, with a suspicion of participation on the part of the left lung is involved. There is considerable exudative pleurisy. The prognosis is not very favorable. Some bacteria have been found in the boy's blood but they have not as yet been identified.

Russia.—It is proposed to increase the salary of the professors of the Military Medical Academy in St. Petersburg. The professors in charge of clinics are to receive 6000 roubles (3000 dollars) a year, while those who are free from such duties will get 4000 roubles (2000 dollars).

The Minister of Public Instruction, who received a gunshot wound during the recent riots, died as a result of suppuration. The number of male medical students is gradually decreasing, while the female students are on the increase.

In 1898 the Russian Government established a monopoly of the liquor traffic, with a view of limiting the sale and abuse of intoxicants. It appears now that within the last two years drunkenness and crime increased considerably.

Sexual Impotence Following Gonorrhea.—Professor Filaretopoulos, of Athens, has written in *L'Independance Medicale* (1901, No. 16), upon sexual impotence following gonorrhea and its complications. Gonorrhea affects the human generative function in two ways, causing inability to copulate, or total absence of spermatozoa. The latter follows orchitis or prostatitis. While theoretically double epididymitis or orchitis ought to prevent the occurrence of spermatozoa, they are, nevertheless, sometimes found. Filaretopoulos has seen four such cases. Following premature erection, which is common with gonorrhea, absolute impossibility of erection eventually results. Gonorrhea may cause latent or apparent spermatorrhea; or it may produce urethral stricture. In some of these cases urethrotomy may effect a cure, virility possibly returning after operation. [M. O.]

The Latest Literature.

BRITISH MEDICAL JOURNAL.

April 27th, 1901.

1. Presidential Address on Traps and Pitfalls in Special and General Practice. J. DUNDAS GRANT.
2. Remarks on the Training of Ophthalmic Surgeons. A. FREELAND FERGUS.
3. On the Advisability of the Inclusion of the Study of Anesthetics as a Compulsory Subject in the Medical Curriculum. DUDLEY W. BUXTON.
4. On Certain Practical Applications of Extract of Suprarenal Medulla. E. A. SCHAFER.
5. Suprarenal Gland Extract in the Epistaxis of Hemophilia. DAN McKENZIE.
6. The Dietetic Value of Sugar. H. WILLOUGHBY GARDNER.
7. A Preliminary Note on the Hibernation of Mosquitos. H. E. ANNETT, and J. E. DUTTON.

3.—Buxton advises that the study of anesthetics be introduced into the medical curriculum as a compulsory subject. He advises a course which shall include lectures dealing with the theory of anesthesia, its physiology, pharmacology and practice. The student should have acutely administered nitrous oxide gas, ether and chloroform. As a minimum, 50 cases might be accepted at which the student has been present and of these at least 12 should have been conducted by him from start to finish. [J. M. S.]

4.—As the result of numerous experiments which have been conducted in Schafer's laboratory by Slight, Malcolm, and Frost, which are not yet published nor entirely finished, he feels justified in suggesting that a trial should be made of the extract of suprarenal medulla in all cases in which it is desired to strengthen or to induce uterine contraction. The observations which have hitherto been made show that his extract has a far greater power in causing contraction of the muscular tissue of the uterus, whether pregnant or nonpregnant, than any other drug having the same reputed action, and this whether the extract be applied directly to the muscular tissue or be introduced into the circulation. Since the active principle is unaffected by the gastric juice, it can be given by the mouth, but in postpartum cases it would doubtless be more advantageous to inject it directly into the uterine cavity, where it would only tend to produce immediate contraction of the uterine musculature, but also of the uterine arterioles, and thus more effectually control accompanying hemorrhage. The solution which I would recommend to be used is an infusion of dry medullary substance, 30 grs. to the pint of water. This should be sterilized by boiling and inject whilst still fairly hot. Such a solution is a powerful styptic, and its value in this respect may be still further increased by the addition of 60 grs. of calcium chloride. Another class of cases in which the extract in question may prove of great clinical value are those of sudden cardiac failure. In these cases the sterilized decoction, which may be of the strength of 5 grs. to a fluid ounce and must be filtered, should be injected with a hypodermic syringe very slowly into a superficial vein, or even, in extreme and apparently hopeless cases, into the heart itself through the thoracic wall. [J. M. S.]

5.—McKenzie reports case of a boy, aged 13 years, who had been suffering from bleeding at the nose for 10 days. A solution of suprarenal gland was applied locally with immediate success. The patient presented a clear history, hereditary and personal, of the hemorrhagic diathesis. [J. M. S.]

6.—The Anglo-Saxon may be distinguished as the sugar-eating race. The characteristics of that race are its energy, robustness and vigor, its pluck, and its power of endurance. The great feature in the metabolism of all carbohydrates is that they are completely oxidized in the

body into water and carbonic acid, without waste, and without residue. Sugar it is not acted upon by the saliva, except in so far as it may be dissolved or further diluted. In the stomach it is partly changed into dextrose by the gastric juice and, to a small extent, absorbed. The greater part, however, passes into the small intestine, where it is rapidly changed into grape sugar-dextrose. It is then quickly absorbed into the portal blood and is carried by it to the liver, where it is stored as glycogen in the hepatic cells. This glycogen is again turned into grape sugar when it is required for use and in this form undergoes oxidation in the tissues, splitting up into CO_2 and H_2O , liberating kinetic energy in the process. This kinetic energy may be utilized either for the production of heat or for mechanical work. Sugar is easily digested and absorbed. It is readily stored up as glycogen, forming a reserve of force-producing material. It is, in this form, readily available when required. It becomes completely oxidized without waste and without residue. It can, under certain circumstances, be converted into fat, in which form, also, it can be stored up in the body and so be capable of producing heat and force in the future. It is also what is called a proteid-sparing food, that is, it will save the wear and tear of the proteids of the body, being used up instead of these substances. Then, again, it is pleasant to take, and thus acts as a relish, stimulating the activity of the digestive processes. So, it would seem that the theoretical considerations derived from a study of the chemical and physiological properties of sugar, the experiments upon animals and upon men in the laboratories, the general instinct of mankind leading it to increase its consumption of sugar wherever it can, the experience of different races in widely different climates, the energy and vitality of the great sugar-eating races, the experience of athletes, and lastly, the experiments conducted upon a large scale in the German army all point to the same conclusion—all tend to show the great value of sugar as an article of diet. If sugar is such a valuable food it is likely to be of value in the numerous cases in which nutrition is at fault, such as simple marasmus, phthisis, and in the condition of malnutrition in those who inherit a predisposition to phthisis. For growing boys and girls it is also needed, and we often find their nutrition suffering owing to a popular prejudice against sugar. For the aged and for convalescents it is probably one of the best of foods. Those who are gouty and fat must avoid sugar, but those who are gouty and thin, while their nitrogenous food, especially red meat, soups, etc., must be strictly limited, may use the sugars and starches without much fear. [J. M. S.]

7.—Annett and Dutton have found that mosquitoes of both genera, *Culex* and *Anopheles*, hibernate during the winter months in England. It seems certain that not only the adults but also the larval forms provide for the continuation of the species during the cold weather. [J. M. S.]

LANCET.

April 27th, 1901.

1. A Clinical Lecture on the Sometimes Successful Treatment of Cases of Apparently Incurable Blindness. CHARLES BELL TAYLOR.
2. On Two Cases Bearing Upon the Question of Limitations of Enterectomy. ARTHUR E. BARKER.
3. On Hour-Glass Stomach; with List of Six Cases Operated upon by the Writer, etc. B. G. A. MOYNIHAN.
4. Reversed Pulsus Paradoxus due to Aneurysm of the Aortic Arch. JOHN HAY.
5. Case of a Parasite—"Argas (or Ornithodoros) Mégnini" Dugès—in Each Ear. J. CHRISTIAN SIMPSON and E. G. WHEELER.
6. A Case of Belladonna Poisoning; Morphia Used as an Antidote. PETER D. STRACHAN.
7. Dermatitis from Arsenic in Stockings. F. W. TUNNICLIFFE.
8. Tetanus Puerperalis. KEDARNATH DAS.
9. Mercury and Iodide of Potassium Internally Given with Pilocarpine Hypodermically in Disease of the Eyes. G. HERBERT BURNHAM.

1.—Charles Bell Taylor, in a Clinical lecture on the sometimes successful treatment of cases of apparently incurable blindness, calls the attention of the profession to electricity as a therapeutic measure which is of especial use on account of the electrical conductivity of the eyeball. The facility with which a current can be passed through the eyeball along the optic nerve to the brain makes it all the more remarkable why electricity is not employed more frequently. He not only considers electricity of value in cases of ocular and facial palsies, but even considers it a means for restoring power in neuritis and degenerative changes such as accompany and follow attacks of influenza, diphtheria, diabetes, typhus, typhoid, rheumatic, and other fevers. He reports a case of blindness caused by optic neuritis in which sight was restored under the employment of a powerful galvanic current. He recommends elaterin in detachment of the retina. He makes a strong plea for vivisection. [M. R. D.]

2.—Arthur E. Barker reports first the case of a woman 58 years of age who suffered from a carcinoma of the transverse colon complicated by a long-standing diabetes. At the time of operation the urine contained 6.6% of sugar. At the operation $4\frac{1}{2}$ inches of the colon were removed and an end-to-end anastomosis made by means of a silk suture. The patient made a good recovery from the operation, and after the use of codeine, the per cent. of sugar decreased rapidly. The abdominal wall suppurated and there was discharged from it a slough of omentum which had been found adherent to the growth and separated at the time of operation. There was for a while a discharge of fecal matter from the wound, but this subsequently ceased, and the wound healed satisfactorily. Barker thinks that where gentleness is used in the manipulation of the tissues and careful asepsis observed that many operations which are now declined might be performed in the presence of glycosuria. The second case reported is that of a feeble woman aged 76 years, who suffered from strangulated ventral hernia. In this case it was found necessary to excise $5\frac{1}{2}$ feet of small intestine, after which an end-to-end anastomosis was made. The patient made a satisfactory recovery, the wound healing without trouble. Subsequent to the operation there was some slight diarrhea, which was easily controlled. Barker thinks that it is oftentimes better to remove a strangulated portion of bowel, the vitality of which is questionable, rather than to return it with the possibility of subsequent palsy, perforation or adhesion. [J. H. G.]

3.—B. G. A. Moynihan discusses first a case of hour-glass constriction of the stomach, and expresses very strongly the opinion that this condition is rarely, if ever, congenital. Acquired hour-glass stomach is attributed to four causes: first, perigastric adhesions; second, ulcer with local perforation and anchoring to the anterior abdominal wall; third, circular ulcer with cicatricial constriction; and induration and fourth, cancer. The usual symptoms of this condition are those of a dilated stomach supervening upon chronic ulcer of the stomach. Two signs which are of assistance here are, first, the fact that upon introducing fluid into the stomach it seems to disappear altogether and does not return through the tube. This, of course, is explained by the passage of the fluid into the second compartment. Second, that upon washing out the stomach until the fluid returns clear, a sudden unlooked-for gush of foul fluid occurs; or if, after apparently thoroughly cleansing the stomach, the tube is again introduced, then through it may pass an amount of foul fluid due to reflux of the contents of the pyloric cavity through the stricture. The author has also observed that upon distending the stomach with CO_2 , the bubbling and gushing of fluid through a narrow chink could be heard with the stethoscope. The symptoms, of course, are influenced by the situation of the constriction. The operation for the relief of this condition will depend upon the condition found at the time of operation, and will consist in gastroplasty, gastro-gastrotomy, gastro-enterostomy and partial gastrectomy. While the process of ulceration is still active it is unwise to perform gastroplasty, but if the ulcer has healed entirely and there are no adhesions, the operation can be done with the expectation of recurrence. When the condition is due to cancer of course a partial gastrectomy must be performed. [J. H. G.]

4.—Hay reports a case of aneurysm of the aortic arch in which the pulse of the carotids and right radial arteries had the reversed character of the pulsus paradoxus.

There was a very marked diminution in the volume of the pulse during expiration, and with the respiratory variations there was present a definite anacrotic wave. Upon post-mortem examination an aneurism was found which involved chiefly the posterior portion of the aorta in the region of the transverse arch. The left carotid and innominate arteries sprang from the anterior surface of the arch instead of from the convexity, on account of the distention of the aorta. With each expiratory excursions these blood vessels were compressed against the bony thorax. [F. J. K.]

5.—Simpson reports a case, in which a live animal parasite, a species of tick (*argas mégnini*), existed in each ear for fully two months without producing local or general symptoms sufficiently severe or annoying to necessitate surgical examination during this time. [F. J. K.]

6.—Stracham reports a case of **belladonna poisoning** in which **morphia** was used as the antidote. The case was that of a boy, five years of age, who had been given a large tablespoonful of glycerine of belladonna. The symptoms of belladonna poisoning developed rapidly. The sulphate of morphia was given hypodermatically on several occasions and recovery followed. The case is of particular interest in view of the fact that the child showed a remarkable tolerance for belladonna and that morphia was an effective antidote. [F. J. K.]

7.—Tunncliffe and Rosenheim give an account of two cases of dermatitis from arsenic in stockings. [F. J. K.]

8.—Das discusses **tetanus puerperalis** and states that on account of the rarity of this almost fatal complication of the puerperal state, he feels that a report of a case, successfully treated, warrants publication. The case was that of a Hindoo female, 23 years of age, who was delivered on July 20, 1900, of a full-term child. The child died on the 10th day of trismus neonatorum. On July 30th the mother developed stiffness of the muscles of the neck and jaw. On August 3 symptoms of tetanus were well defined. There was opisthotonos, the jaw was locked, the temperature was 100.2°F., and the pulse rate 120 per minute. An enema of soap and water was immediately given and followed by a rectal injection of 40 grains of chloral hydrate. Five grains of calomel were administered by mouth and a uterine douche of bichloride of mercury was given at once. During the course of her illness she was kept under the influence of chloral, and apomorphin was administered hypodermatically. On several occasions intracellular injections of normal salt solution were employed so as to aid in the elimination of the toxin. The spasms subsided in about six weeks. [F. J. K.]

9.—Bernhan highly recommends the use of mercury and iodide of potassium internally, given with pilocarpin hypodermatically in disease of the eyes. This treatment was used successfully in a case of sclero-keratitis and in a case of acute sympathetic ophthalmia. [F. J. K.]

MEDICAL RECORD.

May 11, 1901.

1. The Toxic Origin of Neurasthenia and Melancholia. M. ALLEN STARR.
2. Potain's Simple and Accurate Method of the Percussion of the Heart (with Post-mortem Verifications). GEORGE M. CONVERSE.
3. The Treatment of Pneumonia, Including the Hypodermic Injection of Saline Solution. F. NEUHOF.
4. Syphilis in the Well-to-do. J. A. McDONALD.
5. Subarachnoid Spinal Cocainization as a Means of Inducing Surgical Anesthesia. E. N. LIELL.

1.—M. Allen Starr describes a type of **neurasthenia and melancholia of toxic origin**, the chief symptoms of which are headache, dull pressure in the head and back of the neck, sensations of fulness in the head, with inability to concentrate the attention, of temper. manifest irregularities of the circulation, shown by cold extremities, and by frequent flushings and burnings. There are general disorders of digestion, frequently with eructations of gas, and irregular and offensive stools. The urine at times contains a large quantity of indican or indoxyl. It is usually irregular in quantity, of high color and high specific gravity, but may be the reverse. A mild state of melancholia is usually associated with the neurasthenia. Patients in this condition present cycles of depression and well being. Starr believes that the cause resides in some toxic agent

which accumulates in the blood during the period of sleep which reaches the point of irritation early in the morning, which is counteracted by the activity of the day, and hence is less intense in its action towards the afternoon. He theorizes that this toxic agent is manufactured either in the intestines or the stomach. As to treatment the diet should be carefully directed, and the alimentary tract treated as indicated. Baths and exercises are of value. [T. L. C.]

2.—George M. Converse advocates **Potain's simple and accurate method of the percussion of the heart** and presents postmortem verifications. The percussion stroke must be moderate in force, precise and single. The percussion must be concentric, that is, must proceed from points situated at a little distance from the heart, some 3 or 4 cm. toward its periphery. On reaching the border of the heart there occurs a slight difference in the intensity of the sound, and what is most important, a sudden rise in pitch. Here the percussion stops. Potain makes a tracing of the projection of the heart on the chest wall which is mapped out by three lines and three angles. The first corresponds to the curved border of the left ventricle, and forms the left boundary of the dulness. The second line forms the right line of the dulness and corresponds to the right border of the right auricle, and to part of the ascending aorta. The third line should correspond to the curved border of the right ventricle, but as this cannot be distinguished, usually by digital percussion, a straight line is drawn from the upper border of the liver at its point of junction with the right border to the apex. Of the three angles, the right inferior has already been determined, since it is formed by the junction of the right border with the lines of the liver. The left inferior angle is rounded and corresponds to the apex. The superior angle, also rounded, corresponds to the point at which the aorta leaves the immediate vicinity of the sternum to take its course backward. With these attentions it will be found that these tracings may be verified exactly by the post mortem findings. [T. L. C.]

3.—F. Neuhoff discusses the **treatment of pneumonia including the hypodermic injection of saline solution**. As to the latter in acute croupous pneumonia, he believes it is a useful adjunct in selected cases. It acts as a powerful heart stimulant when other remedies can no longer sustain the flagging circulation. It increases the secretions, moistens the tongue and throat, as well as the skin, and lessens delirium. It is contraindicated in pulmonary edema. [T. L. C.]

4.—J. A. McDonald contributes a paper on syphilis in the well-to-do. In 145 adults with acquired syphilis he divided the cases in the following manner. 1st. (and to which 65% belong), were those having mild transitory lesions which left no trace when they had disappeared. The 2d class included 26% of the cases, were those showing destructive lesions of any sort whatever, from the pustular eruptions which left scars, to the necrosis of bones. In the 3d class, numbering 6% of the cases, were included those which exhibited considerable severity for a time, but which finally cleared up completely, leaving no trace. He concludes that the prognosis of syphilis should not alarm us, especially in the well-to-do, in whom it seems particularly amenable to treatment. [T. L. C.]

5.—E. N. Liell presents a contribution to the study of **subarachnoid spinal cocainization** as a means to inducing surgical anesthesia. He mentions the usual causes of failure which may be due to inert cocain solutions, idiosyncrasy to the drug, faulty technique, or too small a quantity of the drug employed. The ill effects of the treatment are nausea and vomiting, headache, increased temperature, increased pulse rate, and sometimes vertigo, pallor and prostration. He believes that this method has passed the experimental stage, and that we are justified in entertaining the hope that it will have its field for practical usefulness along with ether, chloroform and nitrous oxide. [T. L. C.]

6. Acute Strangulated Femoral Hernia on a Puerto Rican Hillside. P. R. EGAN.

3.—Fordyce's treatment for tuberculosis of the skin is as follows: (1) Depends upon the form; (2) The extent of tissue involved; (3) Locality implicated. In tuberculous ulcerations about the orifices, usually preceded by grave pulmonary or intestinal tuberculosis, in most cases local remedies which alleviate without holding out any prospect of permanent cure must be used. Iodoform is the best, as it relieves pain and promotes healing. A more radical remedy is the Paquelin cautery under local anesthesia. Anatomical tubercle and other forms of papillary tuberculosis of the extremities are best removed by the curette after local anesthesia. Total excision of the patch with skin grafting is also recommended, especially in lupus of the face. [T. M. T.]

4.—Freudenthal states in his article on primary chancre of septum of the nose that it is not always essential that a lesion of the epithelial layer be necessarily present before a syphilitic infection can take place. Most of the cases of extragenital chancres occur in and around the mouth and in many instances a lesion has not been found. It is well known that the virus of syphilis is one of the most energetic and certain of animal contagions, and exerts its power whenever and wherever it can find a suitable opportunity differing from tuberculosis. The condition is mostly transmitted by kissing and through drinking cups, and at the present day is not very frequent.

[T. M. T.]

5.—Onuf gives the special characteristics of cerebro-spinal syphilis to be paralysis of single cranial nerves, especially that of the ocular nerve. Recently Sachs has pointed out the irregular manner of contraction of the pupil, in cases of cerebro-spinal syphilis, and believes it to be characteristic. The author says that there is no doubt that it is frequently met with in this disease, but is also observed quite commonly in general progressive paralysis and sometimes locomotor ataxia. He does not entirely agree with Sachs, and thinks the irregular shape of pupil is not so typical as the very contracted or pin head pupil which is more characteristic of syphilis, than the irregularly shaped pupil. Vertigo is another symptom which should put one on one's guard for cerebral syphilis, although it occurs in other diseases. [T. M. T.]

2.—Hiss gives the following conclusions in his article on typhoid fever, dividing them into general and hygienic. Under general conclusions, he gives: (1) During the course of typhoid fever, usually after the first week, typhoid bacilli can frequently be obtained from the blood, spleen, rose-spots, urine, and feces, and in rarer instances, it is claimed, from the secretions or exudations of the mouth, throat and lungs. After death the bacilli have been demonstrated in these and other locations and lesions, such as the lymphatic tissues of the intestine, the mesenteric glands, bone-marrow, lungs, liver, kidneys, gall-bladder, etc.; (2) The bacilli, as far as can be determined from various observations, do not thrive or even survive long in the circulating blood. They are, however, able to live and multiply at some, at least, of the points at which they are deposited by the blood and lymph, thus forming bacterial foci within the tissues; (3) Morphological examinations of tissue sections to determine the relation of the bacilli to the lesions of typhoid fever have in most instances proved unsatisfactory and have given inconstant results. Some of the lesions, without doubt, occur at points remote from the bacilli. On the other hand, it is probable that the bacilli are intimately associated with many of the lesions, since wherever the bacilli, after gaining access to the tissues and fluids of the body, find lodgment and establish foci, the various products of bacterial metabolism and degeneration are thus concentrated and doubtless give rise to lesions at these points. Moreover, it is not unlikely that certain lesions occur only at points of localization of the bacilli; (4) Typhoid fever, therefore, is an infectious disease, in which a wide dissemination and multiple localizations of the bacilli are frequently demonstrable both during life and after death. During the course of the disease various tissue changes take place, some necrotic, others hyperplastic. Some of these lesions are at points remote from the inciting organisms; certain facts, however, point strongly to a close association of the bacilli with some of the more characteristic lesions, especially those of the lymphatic tissues; (5) There is a close connection, in time at least, between the appearance in, and disappearance from the intestinal contents, of the typhoid bacilli and the appearance and repair of the intestinal ulcers. The organisms are only very rarely demonstrable in the stools before the first days of the second week and disappear with the fall of the fever. During the period at which intestinal tissue destruction is most active they can be isolated with great regularity. When continuously absent in typical cases, this may be looked upon as indicating a probable scarcity or absence of intestinal lesions; (6) The urine in a certain percentage of cases contains the bacilli, though not often before the end of the second week. The organisms may not appear until very late in the disease or during convalescence. They may persist for days, weeks, and it has been claimed, for months, and are generally associated with albuminuria. Under hygiene: (1) The urine of typhoid fever patients should always be disinfected. From a hygienic standpoint bacteriological examination of the urine of patients convalescing from typhoid fever is important and should never be omitted before patients are allowed to go at large, so that proper precautions may be taken to guard against the dissemination of typhoid bacilli by the urine. This is an often neglected source of infection that should be seriously considered in the hygiene of typhoid fever; (2) Feces, of course, should be disinfected at all stages of the disease, but the organisms being present generally only from the beginning of the second week to the fall of the fever and the patient during this period usually being confined to bed, the feces are not such a source of infection to the community at large as the urine; (3) The bacilli may, on account of the lung and throat lesions, be present in the mouth of those suffering from typhoid fever, hence, the expectoration should be disinfected, as well as all eating utensils, etc., used by the patients. [T. M. T.]

4.—Trowbridge gives in rupture of the kidney the signs and symptoms as follows: A history of violence over the organ; hemorrhage per urethra; a sense of fulness about

the kidney, often discoverable by palpation; pain extending into the groin and testicle of the same side; weak pulse; pallor of mucous surfaces and skin, and signs of collapse. All these signs vary with the extent of the injury, although he does not think signs and symptoms should always be taken as an indication of the extent of the rupture. The hemorrhage may be severe, the blood clotting in the bladder and blocking the urethra, or it may be so slow, that in the absence of an exploratory operation the surgeon is misled, and sepsis and peritonitis result from too long delayed operation. [T. M. T.]

BOSTON MEDICAL AND SURGICAL JOURNAL.

6. The Fevers of the Philippines. JOSEPH J. CURRY.

1.—Harrington's article is a review of the literature concerning the transmission of typhoid fever by eating raw oysters.—[J. M. S.]

2.—The general experience of the past 4 or 5 years tends to confirm the favorable impression of the value of the Widal reaction as a diagnostic sign in typhoid fever. The usual 95% of successful results indicates, certainly, a valuable diagnostic aid. The limitations of the test, however, as to the time of its first appearance, which is rarely before the sixth day and often not before the ninth or tenth, are such as to deprive it of the value that one would like to attach to it for early diagnosis. Withington gives the results of the application of this test to the cases of typhoid fever in the Boston City Hospital for 6 months. During this period there were 253 cases of typhoid fever in the institution and of these there were 4% of failures. The author excludes 6 cases in which the evidence of typhoid fever is not conclusive, but in which the diagnosis of typhoid fever was made. If these cases are included there will be 259 cases with failures in a little over 6%. [J. M. S.]

3.—Shattuck refers to the paper of Withington, No. 2, as confirmatory of conclusions reached by him, in 1897, in a paper read before the Association of American Physicians. In his recent service at the Boston City Hospital there were 62 cases of typhoid fever, clinically, of which 3 failed to respond to the Widal test. [J. M. S.]

4.—The typhoid of city origin may be atypical and puzzling; care and restrictions may be as prolonged, but it is without the terror, the destructiveness, the lethal drift characteristic of country typhoids. Whittier refers, in his paper, to an epidemic of typhoid fever at Marton, Mass., due to eating raw oysters. [J. M. S.]

5.—Page refers to the method of Rémy, which was published in *Annales de l'Institut Pasteur*, Vol. XIV, 1900, and Vol. XV, 1901, for the separation of the bacillus typhosus from the stools and quotes his results. [J. M. S.]

6.—Some of the typhoid fever seen in the American troops in the Philippines may have been imported to Manila from San Francisco. But the great source of sickness among our soldiers was the old Spanish camp-grounds that our troops were obliged to occupy for military reasons. Malarial fever and dysentery were prominent features among the soldiers that were encamped on these old Spanish camp-grounds. At the First Reserve Hospital there were 653 cases of typhoid fever and of this number 15% died, a remarkable result for a tropical country and a high recommendation for the Medical Department of the Army. The immediate cause of death in over 1-3 of these cases was intestinal hemorrhage or perforation. The death rate was higher after the Philippine insurrection than before the outbreak, this is to be explained by the fact that the soldiers infected during the

existence of hostilities were more fatigued and had less resisting power. Curry has seen 16 cases of Malta fever among the soldiers in the Philippines. Compared with other tropical countries the malarial fevers of the Philippines are not severe. However, out of 20,000 cases admitted to the First Reserve Hospital, 23% were cases of malarial fever. The types met with are the same as those seen in other tropical countries. In the Philippines, however, the tertian type was much more common than the estivoautumnal variety. Out of 1,187 blood examinations malarial parasites were found in but 223. This is accounted for by the fact that as soon as an American soldier begins to have fever he begins to take quinine. The Anopheles are very common in the Philippines where malaria is common. There are many fevers of obscure origin met with in the Philippines which are being studied by the Army surgeons. It is possible that many of these will prove to be cases of Malta fever. There is a class of cases characterized by jaundice and enlargement of the liver that are known as hepatic fever. In a fatal case of this type there were multiple abscesses of the liver without previous dysentery. There was an acute duodenitis and the liver infection may have come through the bile ducts. [J. M. S.]

1.—James H. Dunn goes very carefully into the diagnosis and treatment of injuries of the head. He first of all lays great stress on the careful examination of the head after the hair has been removed. Shaving of the head not only enables the surgeon to observe the injury to the part, but also to observe and note the natural irregularities of the skull which otherwise might later be made the basis of a claim for damages. A hematoma with a hard rim about it is not infrequently mistaken for a fracture, but if steady pressure is made with the finger over this rim it will be found that an impression can be made in it, which would not be true if it were bone. He urges upon the general practitioner the great necessity of cleansing the nasal, oral, and aural cavities in all cases where a fracture of the base of the skull is diagnosed or suspected. The careful keeping of notes, both as to history and as to progress is advised and the giving of a most guarded prognosis. Excepting where symptoms of compression are marked or there is

hemorrhage which demands immediate operation, it is better not to operate at once in fractures of the vault but to wait until a thorough preparation of patient, instruments, etc., can be made, as sepsis is most important in these cases. Where depression is suspected it is better to make an exploratory incision rather than to remain in doubt. Dunn is of the opinion that it is better where symptoms would indicate a lesion of the brain on the side opposite that of injury, to trephine first at the point indicated by focal symptoms and then at the site of injury only in case of clear indication. The symptoms and treatment of rupture of the middle meningeal artery are next detailed. The author expresses the opinion strongly that many more cases of fracture of the base of the skull recover than is generally supposed. The deaths occurring late from this condition are usually due to infection and hence the greatest care should be observed in keeping the connecting cavities as clean as possible, by means of frequent spraying with antiseptic solutions. Brain abscess occurring from fracture of the base is usually so deep-seated and diffuse as to be beyond treatment and not infrequently there are multiple foci of suppuration. The prevention of cortical irritation from adhesion of tissues is next spoken of, and the author thinks that all the methods heretofore suggested of placing gold foil, gutta-percha tissue, egg-membrane, etc., between the scalp and the dura are impracticable and in most instances productive of cyst formation. The replacing of bone buttons or chips of bone is not recommended because of the tendency to necrosis; the later also excite connected tissue proliferation and produce even more pressure by cicatricial formation than would otherwise be the case. The author does not advise the use in traumatic cases of the plates of gold, silver, platinum, or even celluloid. He thinks that the best results are obtained by the careful preservation of the structures as they are divided and their careful and separate suturing after the operation is completed. The use of the osteoplastic flap is highly commended where it is practicable. The technique of opening the skull is finally described. [J. H. G.]

2. Martin, in speaking of the pelvic relations, remarks that under normal circumstances the free upper wall of the bladder does not lie in contact with the anterior wall of the uterus. That space, when not occupied with the bladder, normally distended, is filled with light, constantly moving, small intestines. If the uterus rested on the free superior wall of the bladder, as usually represented, it would never have a minute of equilibrium, but would constantly be moving about as the bladder filled and emptied, and as the cervix would remain comparatively stationary, the intra-abdominal pressure would impinge on a different portion of the uterus almost every minute of the day. His reasons for believing that the uterus occupies this position are the following: 1. Because it is the only position that the uterus can occupy in which it would not be subject to constant important changes in position with the normal changes in the bladder and rectum. 2. In this position the intra-abdominal pressure impinges on, or just posterior to, the narrow crest of the uterus in the direction of its line of axis, and in such a way as to equally distribute the force to all of its supports; and the organ in this position does not receive the whole impulse of the intra-abdominal pressure at one point, but it is equally distributed to all parts of its surfaces and is divided by its lateral, posterior and anterior support. 3. On opening the abdomen the uterus, when not pathologic, almost invariably lies in the position as described above with the space between it and the bladder filled with light coils of small intestines. Three things are important to bear in mind in the blood supply of the pelvis: 1. The arterial supply to the pelvic organs is derived from widely separated points and is provided with the freest anastomoses. 2. The veins of the uterus contain no valves. 3. The left spermatic or ovarian vein enters the general circulation at a disadvantage, as it enters the left renal vein at right angles, while the right spermatic vein enters di-

rectly the vena cava at an advantageous angle. [W. A. N. D.]

3.—B. R. Schenck reports 4 cases of calculi impacted in the ureter which were operated upon by Professors Kelly and Halsted. The first case is that of a woman aged 29 years. Dr. Kelly here made a diagnosis of calculus impacted in the ureter by catheterizing the ureter with a wax-tipped catheter. The catheterization of the opposite ureter showed the kidney on that side to be healthy. The operation was performed by the peritoneal and extraperitoneal incisions. The left ureter was nodular and enormously enlarged, being the size of the colon and very adherent. A rough calculus 1 2-5" x 3-5" completely occluded the ureter. Gauze drainage was employed after the removal of the kidney and ureter. The patient made a good recovery. Case No. 2, a woman aged 37 years. This patient gave a history of repeated attacks of hydronephrosis, but for the last six weeks the condition had been permanent. Upon opening the abdomen the kidney was found enormously dilated, its cortex being about ½" thick. 370 c.c. of pale urine was evacuated together with a small stone. Two other stones were removed from a point 1 1-5" below the renal orifice. This was accomplished with difficulty and required an incision in the ureter 1 2-5" long. The incisions in the pelvis and in the ureter were closed with interrupted silk sutures. A gauze drain was employed and the patient made a satisfactory recovery. Case No. 3, a woman aged 32 years. This patient had suffered for a long time with pyuria. Hydronephrosis was present on admission. Catheterization of the ureters showed the left to be patulous but scratch marks were visible on the wax tip: the right ureter was partially obstructed about 2 3-5" from the bladder and several deep scratches were visible upon the catheter. A radiograph showed a shadow in the region of the left kidney and another on the right side lower down. A lumbar operation was done on the left side and a large amount of purulent urine was withdrawn, together with a large calculus. There was considerable hemorrhage at this time and operation on the right side was postponed until about a month later, when an exploratory laparotomy revealed a calculus located about 2 3-5 inches from the vesicle opening. This was removed through the vaginal vault and the abdominal wound closed. Previous to this operation a ureteral catheter had been introduced and was used as a guide during the operation. It remained in place for 16 hours after the operation and during this time drained 660 c.c. of urine. The vaginal wound closed after draining urine for a short time and the patient made a good recovery. Case No. 4 was a woman aged 56 years. This patient suffered from hydronephrosis and examination of the ureter with a wax-tipped catheter showed a calculus to be situated high up near the kidney. At the time of the operation by Dr. Halsted it was found that this calculus had descended considerably lower in the ureter and it was removed through the vaginal vault. Urine drained through the vagina for some time and ceased entirely on the 16th day. The patient made a good recovery. The author then classifies 84 cases operated upon for stone in the ureter. In 19 of these the calculus was located within 6 cm. of the kidney; in 8, at or near the pelvic brim and in 41 within 5 cm. of the vesicle opening. [J. H. G.]

4.—Vineberg gives the following conclusions from his study of the differential diagnosis of ectopic pregnancy with especial reference to the symptoms of early uterine abortion: 1. Ectopic gestation is diagnosed very frequently as early uterine abortion. 2. It is advisable to look with suspicion upon every case presenting apparently the symptoms of early uterine abortion, and if the case is not running a simple and natural course to fully anesthetize the patient for a rigid examination and for the proper performance of curettage in the event of uterine abortion being present. 3. If after carrying out this plan there still be some doubt, the advisability of making a posterior vaginal exploratory incision should be considered in order to determine the presence or absence of blood in the peritoneal

cavity. The so-called pathognomonic signs of ectopic gestation are unreliable. [W. A. N. D.]

5.—Leonard Freeman reports a case of union following pathological fracture of the femur due to secondary carcinoma. This patient was a woman aged 35 years on whom the author had twice operated for carcinoma of the breast. After the second operation there was no return of the growth. The patient, however, complained of pain in the dorso-lumbar region and on the external surface of the left side of the pelvis. In turning over in bed the patient broke her left femur at the level of the lesser trochanter. There had been no pain or tenderness at this point and nothing to call attention to the process going on within the bone. Extension was applied and four weeks later firm union had resulted. The patient died shortly after this and post-mortem examination showed a secondary growth at the seat of fracture, and firm union had taken place at this point. The second case reported is that of a man 38 years of age who gave a history of having had an ulcerated sore upon the lip which disappeared without treatment and did not return. About a year after the disappearance of the ulceration glandular enlargement occurred below the jaw and was twice operated upon. At the time of the author's examination there was a large inoperable, deeply ulcerated, indurated mass over the right inferior maxilla, the neck and side of the face, microscopic sections of which showed it to be a typical epithelioma. The author believes the original sore upon the lip to have been of the same character and this growth to have been secondary to it. The patient gave no history or evidence of syphilis. [J. H. G.]

6.—Randolph Brunston discusses the rational use and limitations of therapeutic measures intended to promote absorption of exudates within the eye-ball. Medicinal measures. He believes that this is a branch of ophthalmology which has been neglected, and that in the eagerness to use the knife and the needle, therapeutic measures are forgotten. Rest, hygienic surroundings and the prevention of all excitement should not be neglected. The iodides are the most reliable of the so-called alteratives. Iodide of sodium is to be preferred to iodide of potassium because it is better tolerated by the stomach. The iodides are frequently given in too small doses, and in conjunction with hot baths much larger doses can be tolerated. Although mercury and the iodides form the sheet-anchor in the removal of exudates caused by syphilis, profuse diaphoresis can be advantageously produced by pilocarpine. Salicylate of sodium has marked value in the absorption of exudates especially in rheumatic subjects or those that have a uric-acid diathesis. Hydrotherapy is a valuable adjunct to the internal remedies. He questions whether the benefit sometimes derived by the administration of mineral waters depends upon any mineral properties they may contain, or whether it is rather the great quantity of water taken into the system which naturally stimulates the elimination. [M. R. D.]

7.—J. H. Bryan reports 5 case of suppurative mastoiditis, the first of which occurred in a six year old boy, and is of interest as it seems to have had its origin in an attack of influenza. In this case there was extensive necrosis of the mastoid process requiring in its treatment the exposure of the lateral sinus for some distance and an extensive wound in the neck. The patient ultimately made a good recovery. [J. H. G.]

8.—E. L. Shurley speaks of the after effects of operations for the removal of adenoid tissue at the vault of the pharynx. The immediate effects of this operation are classified as hemorrhage, injury to the pharynx, reactionary acute inflammation of the pharynx and accessory cavities and sepsis. The remote effects are subacute inflammatory conditions of the pharynx, the ear, accessory sinuses and tuberculosis. [J. H. G.]

9.—Sawyers considers the treatment of actinomycosis from a medical stand-point. He gives a report of a number of cases, his chief object being to call attention to the frequency of the disease, especially in agricultural communi-

ties, and to direct attention to the most satisfactory plan of treatment of the cases coming under his own observation. The author concludes that the disease is not an uncommon one, and that when uncomplicated it is a non-suppurative, slow-progressing, afebrile, and a comparatively painless disease. Often the signs and symptoms of the disease are pathognomonic. Referring to the characteristics of the micro-organisms he states that the coccus-like bodies are most constantly found, the threads less frequently, and the globe-shaped bodies are often absent. The most favorable results have been obtained by combining surgical measures and the administration of potassium iodide. A large percentage of the cases being cured by the internal use of the iodide potassium. Hypodermic injection of iodide of potassium into the diseased areas produces a marked curative influence. [F. J. K.]

10.—Robinson states that the subject of tropical diseases has assumed new importance to the medical profession, and in this connection abscess of the liver has especially attracted attention. The author gives a detailed report of a number of case of tropical abscess of the liver, stating that they are usually multiple and that the right lobe of the liver has been found most commonly affected. Attention is called to the fact, that the symptoms of liver abscess afford little aid in the establishment of the diagnosis. The detection of pus by aspiration is the means by which the diagnosis can be absolutely made. In his cases a general anesthetic was given while making the exploratory puncture. The needle was introduced to its full extent in five or six different directions in the eighth intercostal space in the midaxillary line. If pus was not found the needle was introduced in other places before abscess of the liver could be excluded in the diagnosis. The finding of pus should at once establish an indication for operation. Robinson states that unless there is evidence of pointing excision of a portion of a rib and drainage from the side is a most favorable method of treatment. [F. J. K.]

11.—Brower points out that as heredity is a most potent factor in the causation of insanity, measures should be directed to regulate marriages and to asexualize degenerates. Before either one of these methods is carried into effect, a great deal of educational work must be done by the medical profession. The medical profession can only direct the proper measures of prevention, while it is a duty of the state to enact laws and enforce them. [F. J. K.]

12.—Douglas C. Moriarta urges upon the general practitioner the great importance of early operation in cases of appendicitis. [J. H. G.]

13.—J. F. Baldwin reports a case of a boy 9 years of age in whom he used the X-rays for locating and during the extraction of a bullet from the knee-joint. The manipulations of the instrument and the location of the bullet in the cavity was easily observed during the operation by means of the fluoroscope. [J. H. G.]

7. Transfusion, Infusion, Autotransfusion. G. W. WAGONER.
8. Litholapaxy in a Child Four Years Old with an Improvised Evacuator. GWILYM G. DAVIS.

2.—W. W. Johnston, of Washington, reports the case of **aneurysm of the ascending aorta** of great size which was treated by **gelatin and electrolysis** with the effect of coagulating most of the contained blood. The question of electrolysis of the aneurysm was discussed for some time and was finally performed by Dr. Finney of Johns Hopkins Hospital. Three unsuccessful attempts were made to reach fluid blood with a canular needle, four inches long passed directly into the tumor. The fourth insertion at a point near the shoulder was successful. Ten feet of silver wire was passed through the tube of the needle. A current of ten milliamperes from a dry cell battery was then turned on and continued for one hour. The operation was comparatively painless except at the beginning. A few weeks after this operation the patient suffered from an attack of intermittent fever. Several large blebs formed near the sternal margin of the aneurysm, some of these finally ulcerated through revealing necrosed fragments of the ribs and discharged continually a thin, bloody serum. Small hemorrhages occurred on several occasions from these blebs, but they were controlled by pressure. The patient died suddenly from a sudden loss of about one pint or more of blood from the point of successful puncture. The autopsy showed that cure had been progressing and there were evidences of recent coagulation about the silver wire. Death was due to the blood current, making channels between the clot and the sac, and finally making an exit through eroded spots on the outer wall. [T. L. C.]

3.—Walter L. Pyle reports a clinical and pathological study of a case of **postpartum metastatic panophthalmitis**. The patient was a well nourished primipara, aged 27 years, who after having been in labor for 56 hours was delivered by forceps. Ten days after delivery the right eye became inflamed and although somewhat relieved by atropine, hot and cold compresses, etc., inflammation continued in violence and persisted for five or six weeks. When the author first saw the case the right eye-ball was congested and atrophic, although the cornea was clear, the iris quite distinct but adherent to an opacity in the pupillary area resembling a calcareous lens. On the following day the eye was enucleated. Microscopical examination showed that the eye ball was phthisical, and had undergone disorganization. The sclera had been ruptured resulting in the evacuation of some of its contents. The rupture had occurred at the posterior portion of the eye ball, to which the author calls attention, as such ruptures usually occur at or near the corneoscleral junction. The literature on the subject is carefully reviewed. Diagnosis, etiology and pathology, prognosis, treatment, as well as the microscopical appearances of each portion of the eye-ball are described. [M. R. D.]

4.—John S. Fulton has made a number of experiments which seem to indicate that **hydrocyanic acid may be found a reliable agent for house disinfection by Boards of Health**; that it is especially servicable in maritime disinfection and alone or in combination with other gaseous germicides very effective against certain infectious diseases. [T. L. C.]

6.—E. P. Hershey reports a case of **double bladder** each with a separate ureter, and presents a report of the study of the urine from each kidney. The patient was 28 years of age before her condition was discovered and had been treated for many diverse conditions. Hershey believes that the condition of surgical left kidney is present with a dilated ureter and collapsed bladder. The left kidney is so far diseased that it secretes urine only at times and when this secretion occurs the posterior bladder fills and the urine is voided by virtue of its own pressure. By means of filling the anterior bladder with methylene-blue, and the posterior with a deci-normal salt solution and subsequently examining the contents of both bladders, it was proven that there was no connection between the two. The posterior bladder was first treated daily with a solution of

creolin gradually reduced to one washing a week. She has gained 15 pounds in weight. [T. L. C.]

8.—G. G. Davis reports a case of **litholapaxy** in a child 4 years old, with an **improvised evacuator**. The case is interesting on account of the rarity of the condition in so young a child. The instrument devised was a No. 18 French Civiale instrument. The stone having been found and crushed an ordinary silver catheter 17 French was introduced. This was attached by means of a rubber tube a few inches long to an ordinary one ounce glass syringe filled with boric acid solution. The fragments were readily withdrawn. [T. L. C.]

VRATCH.

March 10, 1901. (Vol. XXII, No. 10.)

1. On the Casuistic of Sudden Irresistible Sleepiness (Narcolepsy). S. Ia. SELTZER.
2. A Case of False Arterio-venous Aneurism. Ligation of the Vein. W. I. LISIANSKI.
3. On the Casuistic of Extrauterine Pregnancy. B. A. FRATKIN.
4. Poisoning by Cream-Tarts in Charkow. P. N. LASHENKOW.

1.—Seltzer reports 4 cases of narcolepsy. All occurred in peasants. One in a young man of 18, the other in a woman of 30, the third and fourth in women of 35 and 40, respectively. In three of the cases the affection occurred independently, in the fourth it was associated with cephalalgia. On the ground of his own observations and those collected from the literature on the subject the author draws the following conclusions: (1) Narcolepsy may occur as an independent affection. (2) A series of depressions, with the influence of pleasurable or—more frequently—grievous mental perturbations. (3) Independent narcolepsy occurs more frequently in persons of limited intellectual development. (4) Sudden sleepiness in general is met with more frequently in persons debilitated by disease; possibly as a result of depressed spirits caused by the patient's being aware of the gravity of the malady from which he suffers. (5) Change of environment and mode of life should have a beneficial effect on the course of the disease. [A. R.]

3.—Fratkin reports 5 cases of extrauterine pregnancy and devotes considerable space to a critical review of the recent literature on the subject. He does not believe that our knowledge of the causes of ectopic gestation is complete, and that it will be 15 years ago that we in possession of more diagnostic signs. Up to the fifth month the diagnosis is at best uncertain. The reason a positive diagnosis is established with greater frequency is to be sought in the fact that, owing to our accumulated experience, the condition is readily suspected. Indications for and various methods of operating are discussed. An expectant plan of treatment is recommended in cases in which attacks of prostration are not repeated. [A. R.]

4.—Lashenkow in discussing the various forms of poisoning by decomposed food points out that in many obscure cases which cannot be elucidated by a chemical examination the poisoning is due to bacterial toxins. In the case studied by him about 200 persons were poisoned by cream-tarts obtained at a well known confectionary. The symptoms were those of gastro-intestinal irritation and varied considerably in intensity, resembling in some arsenical poisoning. They all recovered. A bacteriologic examination of the cream mixture which is usually composed of milk, eggs, sugar, flour and pastry showed the presence of *streptococcus pyogenes aureus* of unusual virulence. A series of experiments established the fact that when the cream mixture becomes sour and is kept in a very warm room the pyogenic cocci with which such mixture is liable to become contaminated develop very rapidly. The suggestion is made that the cream-mixture be heated to 80.00°C. and the tarts kept in a cool place after they are finished. Moreover, the manufacture of cream-tarts in very hot weather should be prohibited. [A. R.]

4. A Contribution to the Study of Metrophlebitis following Labor. B. A. LIBOFF.

1.—Will be abstracted when completed

2.—Orlowski presents a preliminary report of his experiments undertaken with a view of establishing the causes of the variations in the alkalinity of the blood observed not only in pathological conditions but also in health. He found that the method of Landois-Jaksch is uncertain and inaccurate, the alkalinity of the blood depending to a great extent on the number of blood corpuscles. He has made observations on 45 patients suffering from diverse diseases, having determined in each case not only the alkalinity of the blood but the hemoglobin, as well as the number of red and white blood corpuscles. The results obtained were very satisfactory. The following conclusions were reached. (1) Engels alkalimeter gives results exceeding the normal to the extent of 106 mlgrm. when litmus is used as an indicator; with lacmoid the error amounts to 119 mlgrms. (2) The alkalinity of the blood in health equals 240-267 mlgrms. of NaOH to 100c.c. of blood, when litmus is used, and 269-299 mlgrms. with lacmoid. (3) In various forms of disease the alkalinity of the blood is in proportion to the number of red blood corpuscles, diminishing with the diminution of the latter and remaining normal as long as these are in normal proportions. (4) In view of this fact the determination in disease of the alkalinity alone is not sufficient to form an idea of its deviation from the normal. (5) Of the accumulation in the blood of acid-salts and consequent autointoxication one can judge only when, with a normal proportion of red blood corpuscles, the alkalinity is diminished, or, should oligocythemia be present, the lessened alkalinity is out of all proportion to it. (6) Such a disproportion, suggesting the possibility of acid intoxication, the author observed in grave cases of diabetes and cancerous cachexia. (7) Small (250 grms.), warm alkaline enemas raise the alkalinity of the blood more than the ingestion of soda, both in health and disease. (8) The increase of the alkalinity of the blood by the administration of alkalies and alkaline enemas is transient. A more extensive report of these observations is promised. [A. R.]

3.—Gabritschewski, referring to the paper of Dr. Wolfson on the same subject, (abstracted in the *Philadelphia Medical Journal*, April 6, 1901), remarks that in his experience the prolonged residence of diphtheria bacilli in the throats of convalescents from the disease is due to some pathologic alterations in the throat or nasal cavity of such persons (adenoids, hypertrophy of the tonsils, rhinitis, syphilitic infections, etc.) In anemic or debilitated children the diphtheria bacilli persist for a much longer period than they do in the robust. It is, therefore, necessary to pay special attention to the soil which favors the harboring of the bacilli. He believes that in cases in which complete isolation is impossible, at least partial isolation should be practiced, in the same manner in which it is employed in cases of tuberculosis. [A. R.]

4.—Liboff discusses at length a form of metrophlebitis which receives but little attention in text-books and is often overlooked. This form is usually local, is characterized by chills, sudden elevation of temperature, taking place late in the puerperium, and extremely rapid pulse, but without any subjective symptoms or visible pathological alterations in the genitalia. In the graver forms phlegmasia alba dolens develops, which serves as a useful diagnostic sign. Occasionally this local affection may lead to a general invasion with a fatal issue. The diagnostic signs are the regular fever, the rapidity of the pulse, which is out of all proportions to the temperature, and the tendency to become localized. As a rule, chronic gonorrhea is the predisposing or exciting factor. Five cases are described by the author to illustrate these points. [A. R.]

BERLINER KLINISCHE WOCHENSCHRIFT.

1. The Hereditary Predisposition to Poisons. E. von BOHRING and KITASHIMA.
2. Work as Treatment for Nervous Patients in Sanatoria. ALBRECHT ERLÉNMEYER.
3. The Tallerman Apparatus. FR. NEUMANN.
4. Experiences with the Tallerman Apparatus. O. ZIMMERMANN.

5. Observations upon the Treatment of Puerperal Fever with Marmorek's Antistreptococcic Serum. M. BLUMBERG.

1.—Experiments have been made in Marburg for years to test the predisposition to poisons, of the different species of animals, and of the different individuals of the same species, in normal and abnormal conditions. Horses of all races and at any age can be made immune to the poison of diphtheria by antitoxin in increasing doses. Even in those horses which died with diphtheria, the antitoxin was found in the blood. Experiments upon apes had similar results. Guinea-pigs on the other hand, always died of diphtheria, even when very small doses of the antitoxin were injected consecutively. Guinea-pigs, however, will live longer when attacked by diphtheria bacilli, if they have had diphtheria antitoxin beforehand. Yet they die eventually, anyway. Mice are almost immune to diphtheria antitoxin, yet are well able to withstand diphtheria bacilli. For there is no increase in the predisposition to the poison of diphtheria following bacillary infection. Animals are predisposed to the poison of tuberculosis in this order: sheep, horses, goats, dogs, cattle, and guinea-pigs. To bacillary infection the order is reversed. White mice are even more rapidly affected by tubercle bacilli than guinea-pigs. [M. O.]

2.—Open air sanatoria for nervous patients were begun by Otto Mueller, who realized that some patients would be much better off with physical work and exercise. This has always been advised for melancholia, etc. But for neurasthenia, work is not to be thought of. Such patients need rest and rest and rest. Should, however, psychopathic complications appear, some regular work will be necessary to distract the patient's attention from himself. But the nervous patient must be distinguished from the neurasthenic, for while the latter is really tired out physically, the former only feels tired, and can do more than enough work, should opportunity present. For him, too, at first, rest will be necessary. Later exercise and work will do immense good. Work will also benefit the hysteric and epileptic physically, but his illness not at all. For chorea, exophthalmic goiter, tetany, paralysis agitans, spinal and cerebral diseases, rest will be necessary. But this treatment is not new, as it was instituted about 30 years ago. [M. O.]

3.—Tallerman's hot air apparatus, invented in 1893, is now well known all over the world. Two sorts of apparatuses are in use, a larger for the trunk, and a smaller for the extremities. The temperature can be raised to 230° F. The only unpleasant cardiac symptoms occurred in frightened, excitable individuals. In arteriosclerosis, myocarditis, or valvular disease, no bad effects resulted. Neumann noted not only temporary improvement, but permanent effect in many cases. He treated gout, sciatica, arthritis deformans, etc., the most severe cases only being baked. In the past year the Tallerman apparatus was used in 70 cases of sciatica and lumbago, in four of which there was no effect; 35 cases of arthritis deformans, two of which remained unchanged; chronic rheumatism, fractures, ankylosis, scleroderma, etc. Some of the cures were marked and immediate. The histories of 23 cases follow. A case of scleroderma which had existed for six years in a woman of 46, was much improved by the hot air treatment. In the most severe cases of arthritis deformans, the effect is always marked. No treatment has hitherto been found so effective in its results. [M. O.]

4.—Zimmermann reports the effect of the use of the Tallerman hot air apparatus in 40 cases. 8 were protracted acute articular rheumatism, 10 chronic articular rheumatism, 12 arthritis deformans, 7 sciatica, and 3 inflammatory flat-foot. In all but seven cases the improvement was great and lasting. In the grave cases the amelioration was most noticeable. [M. O.]

The Reductive Action of the Blood After Chloroformization.—At the recent meeting, at Nancy, of the Congrès des Sociétés Savantes, (*Revue Médicale de l'Est*, 1901, No. 8), Professor Garnier reported the result of a number of experiments made by Dr. Lambert and himself. After the inhalation of chloroform, the glycogen in the liver decreases, while the reductive power of the blood increases. The action of chloroform upon the blood *in vitro* confirmed the results obtained *in vivo*. Garnier believes that under these conditions hydrolysis of the glucose occurs, with the formation of a fermentable sugar belonging to the hexose group [M. O.]

Original Articles.

THE DISINFECTION OF WOUNDS WITH PURE CARBOLIC ACID.

BY PROFESSOR DR. VON BRUNS.

of Tuebingen, Germany.

From the 1 with permission of the author, by Max P. Drake, Spert.

Although our methods for rendering operative wounds aseptic have been productive of a certain definite result, there is, nevertheless, still more to be desired in the treatment of infected wounds. The times during which all good results were expected from antiseptic irrigations, are passed. Antiseptics came into discredit because the danger of poisoning accompanied their employment, as carbolic acid and sublimate, and also because, when coming in contact with the albuminous secretions and tissues of the body, they lost their efficiency, like corrosive sublimate, etc. We were soon convinced that no disinfection could render a septic wound aseptic, and even ascertained, by comparing the efficiency of the aseptic and antiseptic treatment of infected wounds, that neither was superior to the other.

The principal value, therefore, has been ascribed to the physical action of the means at our disposal: free incision exposes the focus of suppuration, the infectious wound secretion is washed off, moist dressings are applied for the purpose of absorbing the secretion, and we attempt to obviate the inspissation and retention of the secretion by frequently changing the dressings. In many instances antiseptics is entirely desisted from and only sterile salt solution employed for irrigation and moistening the dressings.

But I believe we should not desist from chemical disinfection, but look for a procedure which is germicidal, without causing injury. I have recently again conducted experiments in this direction, which promise favorable results, although the latter are not yet conclusive. This consists in disinfection with pure carbolic acid.

This may cause considerable hesitation, especially when the times of Lister's carbolic acid antiseptics are thought of, and also the innumerable cases of eczema, intoxication, marasmus, and gangrene, caused by carbolic acid. All this was attributed to the employment of dilute solutions, and consequently one should suppose that the concentrated solution, 96% carbolic acid, would act even worse. This apprehension is at first disproved by Lewis's method of treating hydrocele with injections of pure carbolic acid into the sac of the delicate tunica of the testicle. The procedure never causes intoxication, and is characterized by the slight reaction and the absolute painlessness after its employment. Recently Phelps has treated wounds with pure carbolic acid, after opening tuberculous abscesses and joints, especially the hip joint, and has recommended this method on account of the brilliant results which he has obtained. The joint is opened freely, scraped out or resected, and then filled with pure carbolic acid, which after one minute is washed out with absolute alcohol. Phelps here considers the alcohol as an

antidote against the corrosive action of the carbolic acid.

By these procedures the applicability of pure carbolic acid to wounds is demonstrated; but before we proceeded with the practical application of the method, certain questions had to be answered in an experimental manner. The experiments were conducted by Dr. Honsall, who will report the results. I will but state, that carbolic acid in concentrated solution is relatively less toxic than when diluted, that its penetrability during its brief influence is but slight, and that the bactericidal action of pure carbolic acid surpasses that of sublimate in albuminous compounds.

In view of these assumptions the procedure of Phelps seems to me to be of considerable value in septic wounds. We have employed it in more than 80 cases of infected wounds, plegmons, suppuration of joints, etc. After incision, and subsequent curetting or excision of the wound, the surrounding skin is protected against the excess of carbolic acid, by wetting it with absolute alcohol; the wound is then thoroughly swabbed with a gauze sponge previously immersed in pure carbolic acid. The amount of carbolic acid employed depends upon the size of the wound, but more than 2-6 gr. was not even used in the largest wound, therefore, not more than is injected in a hydrocele sac and left there with impunity.

Not only is this cauterization with carbolic acid not particularly painful, so that it may be performed without anesthesia, but the subsequent pain after fresh incisions is also remarkably slight. Particularly remarkable is the small amount of secretion after the first dressing, so that the latter may remain from 2-4 days in cases where otherwise the dressings would have had to be regularly changed after 12-24 hours. For example, in a case of resection of the hip joint, performed on account of grave, acute puerperal suppuration, the first dressing was allowed to remain four days, during which the temperature was nearly normal.

From this alone it follows that carbolic acid applied but once markedly influences the condition of septic wounds. The course, as a rule, is simpler and less interrupted than is ordinarily observed. Local injury was never noticed, neither a trace of toxic symptoms, and not in a single instance, carboloria.

The result obtained obviously depends upon the fact that carbolic acid belongs to the few antiseptics, whose germicidal power is not weakened by the secretions and tissues of the body. Pure carbolic acid destroys with certainty the bacteria on the surface, and also those in the most superficial layers of the wound. In addition, the superficial sloughing brings about a reaction in the deeper layers, which assists in the demarcation and desquamation of the septicly infiltrated areas, thus assisting, as it were, in the cleansing process of the wound.

I do not hesitate to recommend the application of pure carbolic acid in small quantities and for one minute, followed by immediate irrigation with absolute alcohol, as a remedy that forms a valuable adjunct to our mechanical procedures in infected wounds. It would be a special providence if that remedy which was the foundation of the whole antiseptic era, and which since then has

again been generally discarded, would be called upon to serve us anew in the battle against wound-infection.

A FURTHER REPORT ON A CASE OF PRESYSTOLIC MURMUR ASSOCIATED WITH PREGNANCY, ETC., ORIGINALLY REPORTED AT THE MEETING OF THE ASSOCIATION IN MAY, 1899.*

By JAMES TYSON, M. D.,

Professor of Medicine, University of Pennsylvania, Phila.

It may be remembered that I read before the Association at its meeting in May, 1899, a short account of a case of presystolic murmur associated with systolic tricuspid murmur complicating pregnancy in a woman who was admitted to the hospital of the University of Pennsylvania with these symptoms and condition. In addition she had a striking jugular pulse simultaneous with systole of the ventricles, a marked presystolic thrill at the apex, and increased area of cardiac dullness. There was a thumping first sound characteristic of a case of mitral stenosis, with sharp accentuation of the pulmonary second. There were associated aggravated dyspnea and distressing cough, emaciation and exhaustion, but no dropsy except the amniotic dropsy. The physical signs are illustrated by Fig. 1. With the birth of her child came, as was to be expected marked improvement of all symptoms, including disappearance of the jugular pulse, replacement of the apex, and probably slight change in the situation

Fig. 1.

of the right border. An enlarged liver could now be recognized. At the date of my first report to the Association her breathing rate was 20, her pulse 60 and the temperature 97.2°, these being approximately the temperature, pulse, and rate for three days

previous. She was discharged thus improved June 21st, and a month later went to work in a shoe factory, and continued to work a part of each day until Christmas, 1899. She could not, however, do a full day's work because of shortness of breath easily induced, an irrepressible drowsiness at times, faintness, and sometimes syncopal attacks. Soon after the new year 1900 she grew worse, and was readmitted to the hospital January 16, 1900.

Fig. 2.

Physical Examination on Readmission.—Negative as to all organs excepting the heart. There is visible pulsation over the left praecordium and the apex beat is visible and palpable, somewhat irregular, in fifth interspace slightly outside the nipple line. A presystolic thrill can be felt. Absolute cardiac dullness begins at the lower edge of the third rib, to the left of the sternum, that of the right border, between mid-sternum and left edge of sternum. Auscultation recognizes a short, rough presystolic murmur at the apex, terminating in a sharply accentuated, thumping first sound, the first part of diastole being also occupied by a murmur. At the tricuspid area a distinct systolic murmur is heard, conducted a short distance to the left of the sternum toward the apex growing fainter as the latter is approached. There is also heard at the base a markedly accentuated pulmonary second sound. (See Fig. 2.)

On April 9, 1900, the following note was made:

Mrs. McC. has been quite comfortable for some time, being up and about the ward. For purposes of examination she is again put to bed. Her temperature and pulse rate have been normal for some weeks; her breathing rate has varied between 20 and 27. On inspection we find chest symmetrical well nourished, and a scarcely appreciable prominence of the left praecordium. Apex beat is not visible, but can be felt in fifth interspace in nipple line. At this time there is no thrill palpable, but sometimes under agitation there has been a thrill since her return to hospital. Relative cardiac dul-

* Read before the Association of American Physicians, Washington D. C., May, 1901.

ness is recognized at lower edge of third rib to the left of sternum, and at the right in the mid-sternal line. Absolute cardiac dulness at the upper edge of the fourth rib and at the left edge of sternum. Auscultation recognizes only a very short presystolic murmur, ending in an exaggerated thumping first sound; this is much less marked than originally. At this time no diastolic murmur except the presystolic is heard, nor a systolic at apex, nor a systolic at ensiform, although there was at time of readmission and at times since. Pulmonic second sound is sharply accentuated in strong contrast with aortic sound. She menstruates regularly and has gained seven pounds since her admission.

She was again readmitted February 1, 1901, having had a cold all winter and grippe early in January, when she went to bed and remained there until admission to hospital. Before the grippe she had at times a smothering sensation, especially when she went up stairs rapidly. During the grippe her lungs filled up and there was copious expectoration, sometimes bloody, especially recently. She could not sleep lying down, and had a few fainting spells. Her feet were swollen once.

On readmission her pulse was 80, breathing 26, and temperature 98.6°. She was somewhat dyspneic, but soon improved after resting, and in a few days seemed quite well. Evidently her condition was vastly improved as compared with the first and even second admission. The physical examination the next day revealed trifling prominence of the left precordium, breathing 20, pulse 78, temperature 97.4°. There was no thrill appreciable in mitral area; the apex beat was in fifth interspace, mid-clavicular line. There was no presystolic mitral murmur, no systolic mitral murmur, or tricuspid murmur. There remained, however, a thumping first sound at apex, though less marked than at previous admissions, growing rapidly fainter as the sternum was approached and disappearing at the

third rib, where the pulmonic element of the second sound was well heard. Percussion found relative dulness to the left of the sternum, at lower border of the third rib, absolute dulness on the fourth rib; for the right border relative dulness at right border of sternum, absolute at about mid-sternal line.

Fig. 3 indicates the area of dulness at the third admission, and the shading at the apex the seat of the thumping first sound. There was, as mentioned, no mitral murmur and no presystolic murmur, although at times the latter seemed to come out culminating in the thumping first sound.

There were in addition, on admission, some physical signs of the pulmonary engorgement, which was responsible for her more serious symptoms at this time, but these rapidly passed away, and she was discharged March 20, 1901, much improved, the last weeks of her stay being rather protracted because I desired her to remain in the wards longer than any real necessity for her so doing.

It is not very usual to have an opportunity to examine a cardiac case at such long intervals and exhibiting so strikingly different stages in returning compensation as this, which furthermore illustrates typically the changing physical signs of mitral stenosis.

AN EXCEEDINGLY RARE CASE OF IMPERFORATE ANUS.

By CHARLES B. KELSEY, M. D.

OF NEW YORK.

Through the kindness of Dr. Nichols, of Barton, Vermont, I am enabled to place upon record the following exceedingly interesting and possibly unique case:

The patient, a man of twenty-four, fairly well nourished, though weighing only one hundred and seven pounds at time of operation, was born with an imperforate anus. The history beyond this is exceedingly meagre from the fact that both his parents died in his childhood; but he knows that the opening was made in the perineum during the first few days of life, and that there has always been a free communication between the bladder and the rectum by which urine escaped per rectum and feces per urethram. He states that he has frequently gone for three months without any fecal evacuation of any sort; and that after such a period it is not unusual for him to fill two chamber-potens full of solid matter. On examination there is found a deep anal depression ending in a narrow, firm undilatable slit running antero-posteriorly, which admits the index finger with pain. The slit is surrounded by and located in firm fibrous tissue. Through this slit the finger impinges upon an immense fecal impaction extending above the umbilicus and filling the entire lower abdomen. Any attempt to break up or loosen the impaction or to pass the finger around it causes intense pain and free bleeding; and the mass is so stony that hardly any impression can be made upon it with the finger. There is no sphincteric power (no sphincter), and the usual fluid discharge existing with impaction is caught in a large sponge which the patient has been always in the habit of wearing against the anus. Under ether it required the united efforts of two men and two nurses forty-five minutes to break up and wash out the fecal mass. No attempt was made to estimate its weight, its size being sufficient indication of the amount, and its stony hardness of the time it must have been present. A sound passed into the urethra revealed an entire absence of corpus spongiosum for about an inch and a half in front of the triangular ligament, its place being taken by a thin membrane which separated the urethra from the rectum. This membrane was absent at one point for a space about one third of an inch in diameter, through which communication with the rectum existed. The malformation was of the general type shown in the

Presystolic murmur and thumping first sound.

Heart dulness.

cut except that the communication was urethral instead of vesical.

The usual incision for colostomy was made on the left side, and, as had been predicted before opening the abdomen, no descending colon was to be found at the usual site. Instead of this an immense muscular pouch was found spreading like an apron over the entire small intestine in contact with the abdominal muscles, and reaching from the anus to the diaphragm. I cannot describe this better than by saying that at first it felt like a greatly dilated stomach, but as part of it was pulled through the incision, it was seen to be at least three times as thick as any human stomach, and that the mesenteric veins spreading over it at regular intervals of a little more than an inch, were two-thirds the size of an ordinary lead pencil. The muscular layer was hypertrophied to such an extent that each fascicu-

A COLONIC POUCH.

lus could be plainly distinguished with the eye. This pouch was replaced and a long rectal bougie passed per anum for a guide. The end of this being brought out of the incision, was found to be enclosed in this same muscular pouch, proving that this was the only descending colon we were to find. It was therefore followed up several inches, when at about the point which I should judge would ordinarily mark the end of the transverse and beginning of the descending colon, it rather suddenly narrowed into something more like a greatly hypertrophied large bowel, and here an artificial anus was established with the usual spur, under the gut through the mesentery. The wall of the gut when cut away still showed a muscularis at least three times the ordinary thickness. Other congenital defects casually noted during the operation were absence of development of the muscles of the left thumb, and almost complete absence of both radial arteries.

It is well known that attempts to establish an anus in the perineum by mere incision in cases of imperforation do not usually result favorably either for length of life or function; but I have never seen a description of the result, twenty-four years later, of nature's efforts to utilize such an opening as was here very successfully made by the surgeon. Cases are recorded, however, of children who have lived to adult life with this deformity entirely unrelieved thirty years (Gross).

THE RELATIONS OF THE PUBLIC TO THE MEDICAL PROFESSION.*

By WM. H. THOMSON, M. D., L. L. D.

To a physician who is conscious of the aims of his profession, it seems but natural to expect the fullest sympathy and co-operation on the part of the public in whatever involves the relations of the public to his profession. One has but to enumerate the long list of deadly diseases which a solitary dweller on an island would never have, to perceive how community of disease is involved in the very word community. In all communities men must constantly give and take in everything, disease included. With children, every school, and with adults, every passenger vehicle affords many chances for illustrating what is involved in the term public health. All this seems plain enough. Therefore, why should not physicians expect to be a generally popular body whenever they appear as a class of professionals, men specially trained to guard the public health?

There are causes, rather than reasons, which account for the comparative failure of the public to appreciate the services of the medical profession to the community as such, and it behooves us medical men clearly to recognize just what those causes are.

We would rank as first the conception of the medical profession as a trade. That it is anything else than a means for getting a livelihood by its members is seldom thought of. Why, therefore, should the public take a special interest in the medical profession more than in any other body of persons who make a living by their business? But with many there exists, besides, the impression that the medical profession is a particularly close corporation, strongly dominated by class feeling, and which aims to monopolize to its exclusive profit the whole field of the treatment of disease wherein it is very jealous of all competitors. Also the common term used to designate members of the regular profession, "doctors of the old school," is coupled in many minds with hostility to all innovation and to modern progress.

Thus it is that one of the most creditable features of our profession in its acknowledgment of a code of professional ethics, which, as the term itself implies, relates to questions of honor in professional life and conduct, is interpreted by many as a purely trades union code of the most despotic nature. That consideration which one gentleman should show to another with whom he is brought in professional relations is also regarded as formulated among physicians into a rigid and artificial systems of etiquette, which no outsider can pretend to comprehend. This widely spread delusion tends to hamper the relations of our profession to the public in many ways. It constitutes the first resource of the charlatan to appeal for sympathy to the generous public against the persecution of the great Union of the Doctors, and that sympathy is very readily granted. Costly experience in the past

has shown us that nothing so often defeats itself as an official condemnation by representative medical organizations of any form of quackery, be it ever so absurd or ridiculous. So soon as our profession publicly arrays itself against anything of the kind, it multiplies its adherents indefinitely. Instead of extinguishing the fire, it simply scatters it.

Another fact which we should bear in mind is that in the present state of public intelligence on medical matters, physicians by no means are regarded as having a monopoly of the knowledge of disease, and least of all of curing it. On the one hand there exists a great world of minds which craves for the marvelous and the occult, and nowhere as in medicine can this tendency find such free play. Such people are ever ready to welcome any prophet or prophetess who hails from the realms of the vast unknown. From Hahnemann down to Mrs. Eddy, and to the apostles of osteopathy, the procession of wondermongers has no end, for the reason that such multitudes of our fellows find it so easy to part with their common sense whenever the subject is raised of our life in the flesh and its ills. As life is a mystery, so is disease a mystery, and therefore the more mysterious and incomprehensible the personage is who talks about them, the higher he or she rises in their estimation. But apart from this indefinitely large class of credulous weaklings, there will be found a very general belief that after all doctors do not know so much more than other people about their own business. The average man privately considers himself as good as any doctor about most diseases, and resents the assumption of superior knowledge by a simply formally qualified fellow-mortal. We physicians are constantly made aware that we live in a world of male and female critics, who feel abundantly able to pass judgment upon us, and they often do so unreservedly. There can be no greater mistake than for a medical man to take it for granted that because he has spent years in the investigation and study of the human body and its diseases, therefore, that he will be considered as knowing a good deal on the subject. The truth is that while in most things else special training and experience are accorded proper consideration, the doctor must not be surprised at any time to find the judgment of some female friend of the patient rule him right out of court.

In view of these and many like facts which bear upon the actual relation of the medical profession to the public, we come to the question, how can these serious evils be counteracted? What is it which makes quackery in any form possible or flourishing? Why is rational medicine so commonly unappreciated? The sufficient answer is, because of ignorance, and of nothing but ignorance. We may truthfully say that it is impossible to over-estimate the ignorance of the public in medicine—there is nothing with which it can be compared for its completeness and universality. The most intelligent man in town is likely to come into the physician's office with his diagnosis already made. "Doctor, my liver is out of order, and I want you to give me something to set it right," when, ten to one, he does not know on which side of his body his liver is. Men would be ashamed

to confess that they did not know a good deal about geography or of history, or that Jupiter was a planet and Sirius a fixed star, while they cannot tell what is the difference between an artery and a vein, or the difference between a bronchial tube and a pleura, or that the meninges do not cover the stomach. Very few, even among the intelligent classes, have anything but the vaguest conception that medicine is a great science, and nothing less. That like every other great science, it cannot be known by ignoramuses, but that, on the contrary, it demands the severest mental training and the most patient and exclusive study to become at all proficient in it.

That there is no marvel like life and like the living body, nor any investigation which can surpass its investigation for the problems which it presents. That the astronomer's task is simplicity itself compared with the world which we turn to with the microscope for its revelations of living structure. No chemistry which compares for intricacy with the chemical facts of life, or any branch of that majestic science which is practically so important. That there is no skill in observation which can surpass what is needed for watching the manifestations of life before perversion, and after perversion by disease. No such courage or readiness of resource demanded in any emergency, as in the exigencies of surgical or of medical practice, and that adequately to meet such crises calls for years of preparation beforehand.

In this connection one may say that nothing would so impress intelligent laymen as some adequate information about not only the wonderful progress of the science of medicine in our time, but also how it is achieved. Medicine now makes no haphazard or accidental discoveries, but only by means of research after the most exacting scientific methods. In this work is illustrated the worldwide and international brotherhood of medical science unparalleled in any other of the sciences. All America, all Europe, and far-off Japan contribute to the great company of investigators, working in the most elaborately equipped laboratories, where every alleged discovery in any department of medical knowledge is subjected to the severest tests known, either to confirm or to disprove it, so that nothing of the truth can escape such general and independent scrutiny. Due to this great modern system of experimental medicine, the discoveries made in medicine in our age are really greater than any of the boasted scientific achievements of the past century for their far-reaching effect upon human welfare. What is the gain to humanity by steam, telegraph or telephone compared with the benefits of antiseptic surgery or of the demonstration of what tuberculosis really is: what, also, is the secret enemy which works in every pestilence, and, lastly, why whole regions of the globe are afflicted with the deadly agent now proved to be mis-called malaria or bad air? These and many more inestimable gains to humanity have been won by the most skilful and masterly processes of investigation which the history of pure science can afford. And yet rational medicine demands that by no other way shall its progress be attempted. Theories and speculations are now quickly brushed aside with common sense and daily painstaking observations checked

by exact experimental tests are allowed any hearing. The result has been that as medical knowledge has become more and more based upon facts, the growth of its vast store of information has exceeded all possibility of acquisition by any one mind, however great. There is no man living who himself knows one-fourth of what is now known about the human body and its diseases. The profession has therefore been obliged to apportion its great field to different bands of workers. But what does this fact indicate as to the impossibility of an ignoramus being ever fit to treat anything, when the most highly trained physician constantly acknowledges that he is not himself qualified to treat everything? Were these truths generally known as they should be, the status of the medical profession in the estimation of the people, would be proportionately raised. People would as soon think of committing themselves or their families when sick to uneducated hands as they would commit the locomotive of an express train to a man who knew nothing about locomotives, or to let a common day laborer have charge of a powerful dynamo. How, therefore, the deplorable nescience of the great mass of the public with the most elementary facts about medicine is to be remedied, is a question of the most practical concern to our profession as a body. Every day furnishes some new illustration of the mischievous effects of this public ignorance on the community itself rather than on ourselves, and it has become, in my opinion, a duty on the part of the profession to take some concerted action to devise measures against this great evil. One of the readier means for this purpose, it seems to me, would be a demand that some suitable plan should be devised for the teaching of anatomy and physiology in the curriculum of every high school, academy and college in the land, and equally for both sexes. It is high time that some acquaintance with the mechanism of life should be recognized as an indispensable requisite in all systems of education fit for the name. Thereby to know something of oneself in the structure and functions of the bodies we have, is equal in importance to the study of grammar, of belles letters, or of the dead languages. To remain four years at college and then leave without knowing virtually anything about how the lungs breathe or the heart beats, or the nerves act, is a satire upon the modern systems of education. Of course, we do not advocate any teaching of medicine as such in this suggestion. What we do maintain is, that as the average man and woman in society has heard at school enough about astronomy to render astrology to them ridiculous, so would a corresponding degree of information given at school about the great facts of bodily life tend to render the quack and the charlatan equally ridiculous and impotent.

But we cannot wait at present for such an educational reform, on account of a public exigency, which though orders like it have happened before, yet in this instance is more than usually acute. A sect has arisen which calls itself both Christian and scientific, whose members prefer to heal disease, first by total banishment of all physicians, and by exclusion of all medical measures, substituting instead ideas and

ideas alone. The first of these all-healing ideas is that there is no pain, and there is no disease, but only mind. The rest of their propositions we have no time to state, nor are we sure that we could state them if we did have the time. We need not be surprised at the numerous following which this sect has received, for by this time physicians ought not to be surprised at anything in connection with medicine in this remarkable country. But it cannot be too publicly announced that the medical profession would not attempt to interfere with any human being believing what he pleases about disease and about doctors. As far, also, as doctors are concerned, they may act as they please and never run up a doctor's bill on any account. But how about the public? It is the public's turn to speak now. Suppose a man finds his next door neighbor regarding a case of smallpox, or of scarlatina, or of diphtheria, in his house as only ideas, and for getting rid of these ideas calls in a Christian Scientist to deal with them by his or her ideas, what then? It may be that his Christian Science neighbor does not even do that, but pays a fee to some 'scientist' to operate through "absent treatment"? The fact is practice based upon this childish delusion is more dangerous than allowing children to play with fire. Allowed to act itself out, cases of the most virulent infectiousness will occur beyond the reach of any timely recognition by those who often alone would recognize them, until hundreds of innocent persons are fatally stricken down by subsequent dissemination of the infection. In that aspect this whole system of doctrine, so soon as consistently carried out, becomes simply criminal. If a separate earth could be provided to which Christian Scientists might be consigned, it would not so much matter, but in this crowded miscellaneous world, we must have qualified guardians who do not believe in smallpox being an idea, but a hideous sickness, and whose only form of absent treatment is to absent the patient himself from everybody as soon as possible. A most stringent law ought to be passed, and most effectively enforced, enacting that every case of disease in the community should be visited at least once by a properly qualified medical man. If a properly qualified medical man has not been called in, then one such man should be provided by the public as its official public authority, whose sole duty then should be to determine whether the patient is sick or not with an infectious disease. Other than that duty he should have nothing more to do. All that he is there for is not for either patient or the patient's friends, certainly not as a representative of the medical profession as such. He should be a public officer only to see to it that the sick one does not become a public danger. But for reasons which we have already adverted to, such a law should not be proposed either by medical men or by medical organizations. It is the public's business to see to such an enactment, and public bodies, other than medical, should take it up. Initiated and advocated by the medical profession, any attempt of the kind will raise multitudes to protest that the doctors are frightened about their business being ruined by the success of these apostles of the new faith, and the old story of futile appeal by our profession to the world will simply be repeated.

GASTRIC TETANY, WITH REPORT OF CASES.*

By WM. GERRY MORGAN, M. D.

of Washington, D. C.,

Assistant to the Chair of Theory and Practice and Diseases of Children,
Georgetown University.

Definition.—Tetany is an affection characterized by the occurrence of, for the most part tonic, but occasionally, also, clonic spasms in the hands, forearms, arms, feet, legs, and in severe cases, the neck, face, larynx and trunk. Consciousness is usually undisturbed, but may be partially or wholly lost; it may be entirely lost at one time and undisturbed at another time in the same individual. The contractions are, for the most part, bilateral, and painful; either paroxysmal or continuous.

Etiology.—Up to the present time there have been several theories advanced to explain the symptom-complex of tetany. 1. The dehydration theory of Kussmaul was the first of these, which has already been proven untenable, and abandoned by him. 2. When the dehydration theory failed to explain the spasms seen in tetany, Germain See decided that tetany was of reflex origin, and certainly there is much in these cases to support this theory. He argues that the spasms are due to irritation of the hypersensitive terminal nerves of the mucous membrane of the stomach, which in turn excite the cells in the brain. If this theory be the true one, it is difficult to explain why tetany is not more frequently met with than it is, in view of the many severe conditions of the stomach with which it is never associated. And, too, the fact that the early weeks of pregnancy are very nearly quite immune to tetany speaks against the reflex theory, because at this time there is an increase in all the reflex phenomena. One case was reported in which a young woman who had been subject to attacks of tetany prior to becoming pregnant, was entirely free from seizures for a period of several months, although she vomited nearly every morning during this period. 3. The third theory is based upon the belief that there are certain toxic substances elaborated and reabsorbed by the stomach which produce the manifestations seen in tetany. This auto-intoxication theory is the one most supported by experimental and clinical research. An increasing number of the foremost observers in this line of research have accepted this theory. Kulneff, as well as Bouveret and Devic, have done much by their admirable experimental work to establish and strengthen the theory of auto-intoxication in tetany.

Pathology.—The opportunities for the study of the pathological changes which occur in gastric tetany have been surprisingly few, and comparatively little has been learned concerning the morbid changes which take place in this affection.

Quite recently an article appeared in the *Centralblatt fuer Innere Medizin*, from the pen of Ferranini, giving the results of his study upon the histological changes in a case of tetany following Reichman's disease, which terminated fatally. In this article he gives a very clear picture of all the pathological changes which were found by him.

On post-mortem examination, the stomach was found enormously dilated. The pylorus and the

upper portion of the duodenum were also dilated, and entirely without hypertrophic alteration, a fact of especial interest, as it shows that stenosis of the pylorus is not a necessary accompaniment of Reichman's disease.

His studies seem to indicate that gastritis does not precede Reichman's disease. He claims to have been able to trace out the different stages in the histological changes *pari-passu*.

In the first stage, the glandular ducts and fundi are dilated, and the parietal cells are slightly swollen and clouded. In the second stage the dilatation increases, the parietal cells become much clouded and swollen and project into the lumen of the glands, and are increased in number. The principal cells are shrunken and decreased in number. The interstitial tissue was not in this stage increased, but later there was a small celled infiltration, slight fibrous thickening, and hyperemia. These inflammatory changes were very superficial and most marked at the outlets of the glands, where in spots small erosions and ulcerations were seen.

In the third stage, all the previously described changes reached their highest degree. The principal cells were almost entirely destroyed. The parietal cells were enormously enlarged, and the number decreased, and in all stages of granular degeneration. In the neighborhood of the most degenerated glands the connective tissue had the appearance of cicatricial tissue. At these points the inflammatory changes could be traced to the submucosa.

He observed in the first stage evidences of hypersecretion only, which is soon followed by hyperplasia of those elements which are called upon to produce the increased secretion. As a further result of hypersecretion there is hyperemia followed by inflammatory processes. From this Ferranini argues that the gastritis is the effect and not the cause of hypersecretion. As a further result of this hypersecretion and hyperacidity, the terminal nerve filaments become irritated, and nutritive changes follow, with, as a final result, dilatation of the stomach.

Numerous attempts to demonstrate the terminal nerve fibrils in the gastric mucosa by the gold-chloride and Golgi's osmo-chromic acid methods, were unsuccessful. Ferranini attributes his failure in this respect to alterations in the nerve terminals. However, I do not think it proves disease in the nerve terminals, because these methods in the hands of the most skilled are uncertain when applied to the nerves of the mucosa.

The kidneys showed very little pathological change. There was only very insignificant increase in the connective tissue development in the liver, which increase was most marked about the bile ducts and blood vessels.

The most important changes were observed in the nerve centers, especially in the motor cells of the medulla oblongata and in the dorsal portion of the cervical cord, where nearly all the nerve cells showed pathological alterations. The perivascular spaces were dilated. The cells were much and variously deformed in shape, mostly longish-oval, biscuit shaped, shrunken at the margins, and especially in the centers of the cells much swollen. The cell

*Read before the American Association of Pathologists and Bacteriologists, St. Louis, Mo., 1900.

walls were much thickened. The cell protoplasm showed various degenerative alterations, from slight alterations of form of the chromophile granules to complete granular disintegration of them, and involving either parts of or the entire cell. Many of the cells were infiltrated with yellow pigment, sometimes to an extreme degree. Other of the nerve cells showed changes of the achromatic substance, which in many places was completely destroyed, leaving vacuoles. The nucleus was usually distorted, often so enlarged as to occupy nearly the entire cell, and usually peripherally situated or protruding from the margin of the cell. The nerve processes were often thin and knobbed.

These observations of Ferranini in regard to the changes in the central nervous system are in accord with those previously made by Weiss, Bonome and Cervisato and others. All clinical and experimental researches go to prove that these lesions are caused by the absorption of poisons elaborated in the stomach. The exact nature of these toxins has not yet been determined, so far as I am aware, although several experimentors have been able to separate certain toxic substances which are capable of producing tetanic convulsions.

Symptoms.—The attacks are usually preceded by premonitory symptoms, as, a feeling of nausea with or without vomiting, or there may be a pain or burning in the stomach, or a tingling in the finger tips, or a sense of unutterable fatigue in the group of muscles about to be affected, as occurred in my second case. At times there may be no warning of the impending attack. The spasms are almost invariably symmetrical, and usually begin in the hands and extend upward to the arms. In a few cases the spasms have begun in the toes and extended upward, involving legs, thighs and trunk. In rare instances the attack began in the hands and extended upward until the muscles of the neck and jaws were affected. These spasms are tonic in character, and either paroxysmal or continuous, or, as Allbutt puts it, either intermittent, remittent, or continuous. The hands assume a position which is designated as the obstetrical hand, so called for obvious reasons. The flexor group of muscles are the ones especially affected. The contractures are painful, and any attempt to overcome the rigidity greatly increases the pain. The duration of the spasm varies from a minute to several hours or even days. Consciousness in most cases remains undisturbed, but may be partially or wholly lost, and further, may vary in different attacks in the same individual. Reflexes are usually normal. Both the electrical and the mechanical irritability of the nerves and muscles of the parts affected are increased for some time after the attack, and are looked upon as characteristic symptoms of the disease.

Prognosis.—The prognosis in tetany depends upon the particular disease with which it is associated, and upon the nature of the attack. In a general way, in mild attacks of short duration, not associated with lesions of the stomach, which are of themselves serious, a favorable prognosis may be made. On the other hand, a prolonged, severe attack accompanying well marked isochymia is a very grave complication, and in such cases the rate

of mortality is very high, being placed by Bouveret and Devic as high as 70%.

Treatment.—The treatment of tetany should be that for the particular gastric disorder with which it is associated. In addition the bromides, especially the bromide of strontium, should be given with a maximum dose in the beginning and after a greater or lesser length of time be gradually reduced.

CASE I.—Mr. I.—, merchant, age forty years; well nourished and robust, of nervous temperament, but of cheerful disposition. His family history was negative in so far as it had any bearing upon his present illness. He had never had an illness severe enough to confine him to his bed two days in succession. Has led a temperate life. Has been troubled with mild attacks of dyspepsia for more than ten years. These periodic attacks have been increasing in frequency and severity until at present they are well nigh continuous. At times during the first three years of this period he was annoyed with spells of dizziness whenever worried or hurried after eating a hearty meal. Seven years ago, after enduring the paroxysms of vertigo for three years, he was attacked suddenly with what he calls "a fit." He was then travelling and one afternoon immediately after an unusually heavy dinner he received a telegram to return home to meet a crisis, and while hurrying to pack his belongings and at the same time worrying as to the outcome of the impending affair he became unconscious and had what was then diagnosed an epileptic fit. When he regained consciousness his arms felt so very sore and stiff that he could not use them for some hours; he was nauseated. For eleven months there was no recurrence, at which time he passed through a second convulsion, which was preceded by a severe attack of nausea and vomiting. Again he noted the excessive soreness and stiffness of the muscles of his arms. These attacks have been increasing in frequency until at the time when he came to me in December 1900 he was having from two to three a week. During the past two years he has retained consciousness throughout some of the attacks, although he invariably falls to the floor with vertigo, unless there be a chair or bench near at hand. During these attacks he noticed that the muscles of the arms and chest alone seem to be knotted beyond his control, and excessively painful; and further, that the attack is invariably ushered in with vomiting of an extremely acid liquid with or without admixture of food. The attacks in which consciousness is lost are not preceded by vomiting, but are usually followed by both nausea and vomiting upon return of consciousness. He says that for some hours before the occurrence of a spasm he has an insufferable feeling of weariness and lassitude. He says he has warded off attacks by drinking a pint of hot water in which he dissolved a table spoonful of baking soda, which caused him to vomit. His friends tell me that during the attacks in which consciousness is lost his hands and forearms are flexed and rotated inward; the fingers and thumbs are flexed and claw-like; and that in the beginning of the attack there are muscular twitchings which gradually become quiet, although the contractures continue. The head is rotated more or less to the right side. The tongue is not protruded, nor has he ever bitten it. His spasms last for three to ten or twelve minutes. For the past ten years he has suffered from severe burning sensations in the stomach and along the esophagus, which are relieved for an hour after partaking of food. He belches very constantly an odorless gas. His appetite is excellent, but he has sense of hunger a couple of hours after meals. Thirst is abnormally increased. If his stomach is empty beyond the usual time for meals he is hungry and nauseated at the same time. His bowels are obstinately constipated, not having enjoyed an unaided movement in fifteen years. Has no pain in stomach or bowels. Has lost only ten or fifteen pounds in weight in the past three years.

Present condition. Heart and lungs normal. Tongue clean and moist, showing no scars or indentations. Breath not offensive. Epigastrium not sensitive to pressure. Splashing sound is produced over the stomach from ensiform process to navel. Moderate tenderness in right iliac region, where there is some increased resistance noted.

On examining the stomach in a fasting condition it was found to be empty. One hour after the test breakfast: acidity 104, free HCl 88; dextrin very much, erythrodex-

trin present. The urine was normal, excepting for large numbers of uric acid crystals present. Feces showed nothing of interest excepting, as has been often noted by me in cases of hyperchlohydria, large numbers of triple phosphate crystals were observed.

The treatment in this case consisted of a suitable diet, with small frequent meals; teaspoonful doses of sodium bicarbonate an hour after meals, to be repeated in an hour if the pyrosis was not relieved. Bromid of strontium in five grain doses before meals. For five weeks after beginning this treatment he had no recurrence of the spasms but thinking himself cured, one evening after a hard day's work he ate a hearty dinner of most ill-favored combination of foods one could well imagine and went to bed shortly thereafter. On awaking in the morning he felt the soreness and stiffness in the muscles of his chest and arms and was told by his wife that he had had another "fit" as a result of his folly. He has had only one other recurrence up to the present time, and that again was the result of over-eating.

CASE II.—Mrs. E—, nearly 60 years of age. Had typhoid fever about 20 years ago, from which she made a perfect recovery, and remained in good health up to three years ago, when her digestive troubles began, since which time she has been gradually getting worse.

Present condition: Appetite is good. Is very thirsty and her mouth is often dry. Tongue clean and moist. About two hours after meals has a feeling of weight and oppression in pit of her stomach, accompanied with "a misery," which lasts until food or magnesia are taken. Often has water-brash. Belches an odorless gas so constantly that it is a source of much annoyance to her. Has no nausea or vomiting. Bowels are regular. Feces and urine are normal. During the past eight or ten months she has been suffering at times from attacks during which she was unable to use her arms, and which last from a few minutes to an hour. These attacks begin with a distress in her stomach which is soon followed by a feeling of weariness and actual pain down the flexor surfaces of her arms, forearms and hands. After a few minutes she uses the power of movement in these limbs; the elbows are drawn close to the sides of her body, the arms, forearms and hands rotated inward; the hands are flexed at the wrists and assume the Trousseau position. During this time the feeling of weariness has passed off, but the pain continues, and any attempt to change the position of either of these members caused greatly increased pain. Twice only have the muscles of the neck become involved. The second time it occurred in my office immediately after I had withdrawn the gastric contents through a tube. While the tube was still in her stomach she began to experience much weariness and pain in her arms. Upon withdrawing the tube a spasm in the upper extremities followed, typical of tetany. After lasting for about two minutes, the head was rotated slightly to the right and backward and appeared fixed. The muscles of the face, jaws and tongue were not affected. In two or three minutes the spasm passed off, leaving her weak and nervous, with stiffness of the muscles of her arms, but none in those of the neck. The following morning I was called to her home to relieve the pain and stiffness in the muscles at the back of her neck. I found these muscles much swollen and painful, which rendered her unable to rotate her head. This condition subsided in about four days.

Examining the gastric contents one hour after the test breakfast: acidity 59, free HCl 53; dextrin present, erythro-dextrin very much.

The treatment in this case was similar to that pursued in Case I, except that in the place of the bromid salt I ordered Phospho-glycerite of Lime in capsules.

In my first case there is much to suggest a complication of tetany with epilepsy, and certain it is that he has two very different kinds of attacks, but having the same after effects, viz.: the marked soreness and stiffness of the muscles, which are at the time affected. That this case is one of epilepsy only I do not believe, both on account of the nature of the attacks, the after effects, and because of the marked relief which has followed the simple treatment which he has carried out, the 20 grains of bromid salt in divided doses daily not being suffi-

ciently powerful to control the convulsions of a well-established epilepsy of seven years' standing. That my second case is gastric tetany may be accepted, I think, without further comment.

THE FUNCTIONAL TESTS OF HEARING.

By WILLIAM LINCOLN POLITZER, M. D.

The value of the functional tests of the organ of hearing as aids in the diagnosis and prognosis in diseases of the ear has for more than three generations been a controversial subject. In spite of this fact they are still used and recommended by most of the great authorities on otology. Much discussion has arisen because of certain exceptions to the general rules laid down by various writers, or on account of an imperfect understanding of the principles underlying the physiological experiments. The fact that three generations of otologists have used them and are using them more generally now than ever before is a fair indication of their utility, and of their fixed place in otologic practice.

I can do no better than quote Prof. A. Politzer in this connection: "The tests for hearing are of the greatest importance in the diagnosis of diseases of the ear; for they serve not only to determine the extent of the disturbance of hearing, but not infrequently also to localize the affection, inasmuch as in cases in which the other objective methods of examination give a negative result, we are enabled to judge whether the anatomical cause of the functional disturbance has its seat in the apparatus for the conduction of sound or in the nerve apparatus. But they are also of special value because by means of them, while the patient is under observation, we can note the course of the disease, and also the result of the treatment."

Some Physiological Facts.—(a) The normal range of hearing, in man, for musical tones is from 16 to about 48,000 vibrations per second. After the fiftieth year the upper limit of hearing is somewhat lowered. Persons seventy or more years old do not usually hear tones of more than 37,000 vibrations.

(b.) Sound waves reach the labyrinth chiefly through the tympanic membrane, the ossicles, and the oval window into which the foot-plate of the stirrup is inserted. As you all know, the foot-plate does not form a bony union with the oval window, but is attached to it by means of a fibrous membrane or ring. This allows it to vibrate freely in the window. Politzer first demonstrated that the malleus performed the greatest excursions, the incus less, and the stapedius least of all. Helmholtz found the greatest excursions of the stapes to be 1.18-1.14 mm. It can readily be seen that slight interference with the movements of the foot plate by either adhesive bands or ankylosis at the window will very materially interfere with the function of hearing.

(c.) It is more than probable that sound waves also reach the labyrinth through the round window, ~~but the importance of the test is not altogether destroyed when the foot-plate is fixed.~~

Read before the Chicago Otolaryngological and Ophthalmological Society, Feb. 28, 1901.

(d.) Sound Waves are also carried to the labyrinth to a considerable extent through the bones of the skull. This explains the somewhat startling fact that certain deaf persons hear tolerably well if the speaker places the tips of his fingers against the forehead of the listener. It is well-known that if when a tuning fork of 512 vibrations is placed upon the skull and the external meatus is artificially closed with the finger, the vibrating fork is heard much better on that side. In other words, bone conduction is thereby increased.

(e.) In the normal ear bone conduction for tuning forks is a little more than one-half the time of hearing by air conduction. Most text books state that it is about one-half. In my text book which appeared last year, I make this statement. This, should be somewhat qualified as the relative duration of hearing by bone and air conduction varies greatly with different forks of the same number of vibrations. It will also vary with the point of contact made with the fork. For instance it is heard a little longer when placed over the mastoid antrum than when placed on the tip of the mastoid. It is customary with most otologists to place it between these two extremes be just posterior to the external meatus. At this point my fork will register in the normal ear about 12 seconds by bone conduction, while it is heard 28 seconds by air conduction. Politzer has wisely called attention to the varying results obtained by forks of the same number of vibrations. Each set of forks should be carefully and repeatedly tested upon normal cases so as to establish its normal register. Gradinigo at the last International Congress of Otologists, of which I had the honor of being a member, gave a scheme for the uniform record of the functional tests, in which he gives the register of his fork. This should be done by all observers. In this way our reports will be of much greater value to otologists in general.

(f.) The tensor tympani and stapedius muscles have long been regarded as the tension regulators of the drum-head, the stapedius counter-balancing the tensor tympani. A few years ago Dr. T. F. Rumbold wrote an article to the effect that they were the tone-selecting muscles of the ear as the ciliary muscles are the view-point selectors of the eye. In other words, that they are the focusing muscles of the ear. He says that through their action one selects the voice from a multitude of voices he wishes to hear; and that they attune the drum-head to catch and transmit to the labyrinth the sound waves desired by the listener.

(g.) The normal ears of a given subject perceive sound in its actual pitch. Both ears perceive it exactly alike. They co-ordinate in pitch timbre and intensity. In certain pathologic states one or both ears may get "out of tune."

In order that we may have a simple basis for the study of the physiologic tests of hearing, I will here quote from my text book* the principles underlying them. I have thus formulated them for use in my clinical teaching and have found them of great value in making the subject attractive and

lucid to students of otology. They are herewith given with slight amendment and explanatory remarks.

The normal range of hearing is from 16 to 48,000 vibrations per second. The upper limit of hearing is lowered after the 50th year from senile changes, independent of other pathologic process.

(2.) When the conduction apparatus is diseased or obstructed the power to hear low tones is impaired or lost.

(3.) When the perception apparatus is diseased, the power to hear high tones is generally impaired or lost. There are cases in which the rule will not hold good, high tones being heard when there is undoubted labyrinthine disease. The exceptions are so rare, however, that the rule is of great value in differentiating between middle ear and labyrinthine disease. As age diminishes bone conduction the rule is not of so great value in testing the aged.

(4.) The normal ear hears about twice as long as by bone conduction. As already stated, this rule should be somewhat modified, as bone conduction for some forks is more than half as long as air conduction, while in others it is shorter. This is not a matter of great importance, however, as the rule applies more particularly to the use of the Rinné experiment, in which the most important question is, as to whether it is positive or negative Rinné. The rule also applies to the Schwabach test, and, therefore, a more accurate statement is desired. In recording the results of the Schwabach test the number of seconds the vibrating fork is heard by bone conduction and by air conduction is noted. For instance, if the normal time of the fork is 12 seconds by bone and 28 seconds by air, and it heard only 15 seconds by air conduction, the rule as above stated would show that either air conduction is shortened. Each fork used for this test should be tested on a number of normal ears and its register determined. In reporting cases the register and number of vibrations should be stated so as to avoid further confusion in this regard.

(5.) When the conduction apparatus is diseased or obstructed, bone conduction is increased and the time left in which the fork should be heard by air conduction is diminished; or bone conduction is often lengthened so as to exceed air conduction in duration.

(6.) When the perception apparatus is diseased, bone conduction is shortened or is entirely absent, so that the relative time of hearing by air conduction is increased.

(7.) In addition to the above principles I might add the following: When the normal ear once clearly hears the tick of a watch upon approaching the patient, it will be heard as if it is gradually withdrawn to a greater distance. The distance to which it may be withdrawn and still be heard varies from 6 to 18 inches. In some cases of impaired hearing there is inability to hear the watch as it is withdrawn beyond the point at which it is distinctly heard upon the approach. Rumbold thinks this is due to weakness of the tensor tympani muscle. I have observed the sign in a number of poorly nourished and neurasthenic cases, in which it might well be true that there was muscle weakness, although

*Eye, Ear, Nose and Throat, Ballenger and Wipperrn, pp. 182-183.

I am not certain as to the significance of this sign.

The Application of the Functional Tests. We are now ready to discuss the application of some of the most approved physiologic experiments pertaining to the ear with the hope of arriving at some conclusion as to their value as aids in diagnosis and prognosis. It is not assumed by the writer that a correct diagnosis cannot usually be made, or at least pretty accurately guessed at, without the use of the functional tests. We grant as much. The only question herein discussed is as to the reliability of the tests in cases in which there is some doubt as to the diagnosis. I may be pardoned for remarking just here that one should make constant use of the tests in order that he may become skillful in their application and in his deductions therefrom. It may be necessary, therefore, for some to make it a routine practice to apply them to all, or nearly all, cases coming under their observation. The writer has for several years made this his practice in both clinical and private practice. He feels that he has been well rewarded for his trouble, and the convictions herein expressed are based upon this experience. They are offered for your thoughtful consideration with the hope that you will add to his knowledge, rather than he will add to yours.

The Watch Test.—This instrument has long been used to test the acuteness of hearing and is of more or less value. The patient may be able to hear the watch distinctly at about the normal distance and yet not understand conversation, or vice versa. While it may not afford an accurate means of diagnosis, it is often a means by which comparisons may be readily made from time to time during the progress of treatment. In catarrhal inflammation of the middle ear, and especially of the Eustachian tube the watch may be heard distinctly one day and indistinctly or not at all another day. This variation is rather diagnostic of this type of ear disease, and is accounted for by the intermittant, through irregular stoppage of the lumen of the tube and the subsequent absorption of the oxygen from the middle ear. When the tube becomes clear again air is restored to the tympanic cavity and the normal tension of the drumhead and ossicular chain is restored. We use two watches, one a high-pitched ticker, the other a low one. The low-pitched ticker is one of the dollar Ingersoll watches, and can be heard at a distance of ten feet, while the high-pitched ticker (a Paillard's non-magnetic Swiss) can be heard at five feet. Prout's method of recording the result of the test is used, i. e., the number of inches the watch is heard by the normal ear is used as the denominator and the distance at which it is actually heard as the numerator. Thus, if the Paillard, or high-ticker, is used and it is heard at 10 inches the fraction ten-sixtieths expresses the result. If the loud-ticker is used and is heard at 30 inches the fraction thirty-one hundred and twentieths expresses the result. There are four ways of using the watch, namely, (a) finding the distance at which it is heard upon approaching the ear; (b) placing it in firm contact with the auricle; (c) placing it against the mastoid process; (d) placing it between the teeth and noting in which ear it is heard the plainest, as in the Weber

experiment; and finally (e) after first finding the distance at which the watch is heard upon approach, and then noting how much farther it can be heard upon withdrawing it from the ear. As before stated, Kumbold uses this test to ascertain the tonicity of the Stapedius muscle. The writer has also used it for the same purpose for the last three years and finds improvement in such cases follows the administration of strychnia, iron, rest, and out-door exercise.

The Voice Test.—In 1871 Oscar Wolf published his conclusions as to the voice as a means of testing the organ of hearing. He found the letter R to be the lowest in the scale, having 128 vibrations per second, while the highest number of vibrations was given by S which gave from 5400-10840 vibrations per second. Hence, by the use of these two consonants we may test the hearing for the lower and within two octaves of the highest musical tones. With marked limitations this experiment may be used to differentiate between disease of the middle ear and of the labyrinth. He found speech in other words to be confined within about $6\frac{1}{2}$ octaves. The greatest strength and timbre belongs to the vowel A, which can be heard 252 m., and the smallest to the consonant H, which can be heard at 8.4 m. distance. And so he goes on to classify the various sounds and letters so that they may be used for testing purposes. There are several objections to this method of testing in spite of the great amount of scientific investigation bestowed upon it by Wolf, Clarence Blake and others. If words are used the patient often hears only the vowel sounds distinctly, and if numerals are used he experiences the same difficulty with the additional one of attempting to infer the number by sequence. Then, too, there is the difference in the quality, timbre, pitch and carrying quality of the voices of different observers. This difference is less pronounced in the whispered voice, especially if it is given out with the residual air. In fact, when the whispered voice is used it should be given only with the residual air, thus rendering all voices more nearly alike. As a careful analysis of Wolf's method would require many pages, it will not be considered further here. Suffice it to say that a thoughtful application of his method will aid the diagnosis, and will be useful in noting the progress made under treatment.

The Politzer Acoumeter.—This instrument was designed to take the place of the watch, or at least to supplement it, and can be heard at about 40 feet. All of the instruments are supposed to be of the same pitch and timbre, but in the mad rush of American dealers I fear little attention has been given to their exact construction. It is, however, a valuable adjunct to the watch tests, and may be applied in the same way, 40 feet being taken for the denominator, and the actual number of feet at which it is heard as the numerator. Politzer and Lucae claim it more nearly corresponds with the voice test than either the watch or distance tests with the tuning forks.

Many ingenious physiologic tests of more or less value have been devised, but after all the most valuable are those made with the tuning forks and whistles. We will now proceed to discuss some of the more valuable ones.

The Range of Hearing.—As already stated, the normal range of hearing for adults under 50 years of age is from 16 vibrations to 48,000 per second. After the fiftieth year this may be reduced to 37,000 per second. In other words, the upper register is lowered by the changes incident to senility. By referring to the third principle we find that high tones are diminished or lost in disease of the perception or nerve apparatus, hence in applying this principle the age of the patient should be taken into account. The upper limit of hearing is also lost in certain conditions of the middle ear, notably in marked retraction of the drumhead whereby the footplate of the stapes is forced inwards against the labyrinthine fluid. This increased pressure so affects the terminal endings of the auditory nerve as to interfere with the perception of high tones. This condition can usually be readily differentiated from true labyrinthine or nerve deafness by inflation of the middle ear. This procedure usually restores the normal tension to the drum-head and ossicles, and thereby relieves the increased intratympanic tension. The upper limit of hearing being restored, the diagnosis can easily be made.

The best outfit for making a complete test of the range of hearing is the Bezold-Edlemann set of forks and whistles. With these every musical tone from 16 to 48,000 vibrations can be tested. This is very important in a certain number of cases, more especially in deaf mutes. It is a well-known fact that a large percentage of so-called deaf-mutes are not totally deaf, but only to such an extent that they do not hear well enough to learn speech. Then, too, some of them can only hear certain tones in the entire range of hearing. In these cases these tones should be ascertained, and they should be trained to distinguish sounds, musical tones, and speech at these pitches. The information gained by this simple test may be made the avenue through which some of these poor unfortunates are brought within the range and influence of the greatest pleasure in life, namely, social conversation with his fellows.

By referring to the second principle we find that in disease of the conduction apparatus the power to hear low tones is impaired or lost. Loss of hearing for low tones is, therefore, usually a sign of middle ear disease or obstruction to the external meatus. It must not be forgotten, however, that the portion of the nerve apparatus concerned in the perception of low tones may be diseased while the other parts are not affected. In this case the loss of low tones would not signify middle ear disease. These cases are exceedingly rare, and would not, therefore, often confuse the observer.

The Weber Experiment.—This is one of the best known and most reliable tests made with the forks. Weber's experiment consisted in placing the tuning fork c2, 512 v., on the median line of the skull, and then closing the external meatus of one ear with the finger, under which conditions he found the sound lateralized toward that ear. Clinically it has been shown that when the middle ear is diseased, or the external meatus is obstructed by cerumen or other morbid conditions, the sound for the vibrating tuning fork (when on the median line of the skull), is lateralized to the affected side; and that when

the labyrinth is affected the sound is lateralized toward the good ear. This rule, like all rules, has exceptions. If the labyrinth and middle ear are both diseased there are manifestly two opposing conditions, one increasing, the other decreasing bone conduction. In such cases dependence must be placed upon a much more extended examination of the case. Indeed dependence should rarely, if ever, be placed upon a single test. Where both the middle ear and labyrinth are affected the Schwaback test will often help to clear the diagnosis. By this test both the bone and air conduction are measured and the variation from the normal may afford evidence of the true condition.

Another exception to the rule which has been noted by several observers, is often found in cases in which both middle ears are affected, but unequally. Ordinarily the fork is lateralized toward the side most affected, but the opposite is often true. Hence in bilateral deafness the Weber experiment is not so reliable as in unilateral deafness.

In simple, or uncomplicated labyrinthine disease, however, the fork is almost universally lateralized toward the good ear. Jacobson and Politzer have never seen an exception to this in undoubted cases. The test seems, therefore, to be a reliable one in this class of cases.

The accuracy of the Weber test will depend very much upon the fork used. In nearly all cases the best results are obtained with fork c2 512 v. Occasionally better results are gotten with lower ones. Higher forks should not be used, as they often give exactly the opposite result. They are almost useless for making this test. In exceptional cases a c2 512 v. fork may not be at all adapted for this test. When we remember that a fork of a higher pitch should never be used we can readily understand why a c2 fork with marked over-tones should not be used. The high over-tones might so counterbalance the true tone of the fork that it would be a question as to which was referred to by the patient in response to the test.

According to Politzer, when the result is questionable the sound will be lateralized if ear specula are inserted in both external meatuses. He also calls attention to the fact that in double chronic middle ear disease the sound of the fork may be lateralized to one side when placed on the vertex and to the other when placed on the maxilla or base of the nose. The writer's experience leads him to depend, chiefly, upon the median line of the upper teeth and the base of the ear.

The Weber test is, therefore, found to be more reliable in unilateral middle ear disease and somewhat less reliable in labyrinthine disease, and still more unreliable in double chronic middle ear affections.

The Schwaback Test.—This consists in ascertaining the number of seconds the fork is heard by bone and by air conduction. The result is to be compared with the normal register of the fork. Thus, if the normal register is bone conduction 10 seconds, and air conduction 20 seconds, and the result in the given case is bone conduction 20 seconds and air conduction 18 seconds, it is a natural conclusion to say that there is an increase in bone conduction, and therefore the deafness is due to disease of the conduction

apparatus. If there is both middle ear and labyrinthine disease the result is very different. It would be something like this: bone conduction 0 seconds; air conduction 5 seconds. Perception by both bone and air being reduced below the normal. In making this test the fork should be placed over the mastoid just posterior to the external meatus. It will make some difference in the result if it is placed over the mastoid antrum rather than the tip of the mastoid. In the former position bone conduction will be a little longer than in the latter. It might afford useful information to make tests in all three of these positions. For instance, if there is a small antrum from sclerosis, bone conduction should be diminished as compared with the normal register. The writer has not extensively experimented in this direction, but only throws out the suggestion for what it may be worth. Dr. A. H. Andrews has done considerable work along this line and speaks of greater differences in bone conduction from the 3 points on the mastoid than have been observed by the writer.

The Rinne Test.—This is only a modification of the Schwaback, or rather a modification in the method of recording and drawing deductions therefrom. In this test only the difference between bone and air conduction is recorded. For instance, if bone conduction is 25 seconds and air conduction is 15 seconds, it is recorded negative Rinne or Rinne -10. If air conduction is 10 seconds longer than bone conduction it is recorded positive Rinne +10. By this test if air conduction exceeds that by bone when applied to the deaf ear there is nerve deafness, and when bone conduction exceeds that by air when the fork is applied to the deaf ear there is middle ear deafness. This test is not so reliable as the Weber, but is nevertheless one that should always be used in conjunction with the others.

According to Lucae the Rinne is only reliable when hearing for whispered conversation is reduced to 1 m.

If there is increase of bone conduction to such an extent that a negative Rinne is obtained the test is pretty reliable. If, however, bone conduction is only increased to a moderate extent and a plus Rinne obtained, it does not afford much information. The more profound the deafness from middle ear disease the more reliable is the test.

If, in examinations, there is a correspondence between the results of the Weber, Schwaback and Rinne tests, the latter is additional proof of the pathologic condition present. Thus, if a patient complains of deafness in the right ear and the Weber test lateralizes to the right side, the Schwaback shows bone conduction 25" and air conduction 15", and the Rinne -10, the Rinne corroborates the other tests and confirms the other signs pointing to middle ear disease. There are many cases in which the diagnosis is in doubt when the information afforded by the various physiological tests render the diagnosis clear. When, however, we get a -Rinne with duration of bone conduction also shortened, there may be some doubt as to the significance of the negative Rinne (—Rinne). In such cases there may be present both middle and labyrinthine diseases. This apparently anomalous result is often very significant,

and should lead to most careful investigation and to a very guarded prognosis. So, it is often the case, that, through the very contradictions arising between the tests that we are enabled to arrive at a pretty correct idea as to the location and extent of the pathologic process.

In middle ear disease of very moderate degree the Weber test is the more reliable of the two.

In the aged the Rinne test is not so reliable on account of the diminished bone conduction incident to senility.

In severe deafness when the Rinne gives the positive result (plus Rinne) it is a pretty reliable sign of nerve involvement.

The tuning fork best suited for making this experiment is c^2 , 512, although it may be made with forks two octaves higher. With higher forks than c^2 it is, however, difficult to eliminate hearing by air conduction. Unlike the Weber, the lower forks are not suited to this test as upon the mastoid, the patient cannot so easily distinguish between the mechanical vibrations and the tone of the fork.

The fork used should have its register established by numerous experiments upon normal ears, and in publishing reports of cases this register should be named.

The Gelle Test.—This test is based upon the physiologic experiments of compressing the air in the external auditory meatus, while the vibrating fork is upon the vertex. At the time of compression the perception for the tone of the fork is greatly diminished in a normal ear. This is due to the increased pressure within the labyrinth. If there is ankylosis of the foot-plate (according to Gellè), there will be no change in the tone, he, therefore, claims it is of value in diagnosing this condition. If, on the other hand, there is marked deafness and the tone is greatly diminished with each compression it signifies that the foot-plate is freely movable, and, that deafness is due to labyrinthine disease. My own personal experience with this test does not warrant me in expressing an opinion as to its value. According to Politzer, it is only of value in cases of severe deafness and even in these cases often fails to afford information.

Bing Test, No. 1.—This test is also used to differentiate between middle ear and labyrinthine affections. This experiment is based upon the fact that when the turning fork upon the mastoid ceases to be heard, it is heard anew when the external meatus is closed with the finger. In cases with pronounced deafness if closing the meatus does not develop the tone anew it is, according to Bing, a sign of middle ear disease, whereas if it is heard again (in cases of pronounced deafness) it is a sign of labyrinthine disease. This test seems to be of value only in very severe deafness.

Bing Test, No. 2.—This test is thus referred to for the sake of convenience of reference, and refers to what Bing calls the "entotic" use of the speaking tube. The purpose of the test is to differentiate between ankylosis of the foot-plate of the stapes, and adhesive bands or other pathologic condition which hinders the malleus and incus in transmitting sound waves. The test is made by comparing the hearing of a patient through a speaking tube applied to the external meatus and one applied to the Eustachian

tube by means of a suitable fitting to the Eustachian catheter. If the patient hears better through the speaking tube by way of the catheter, than he does through the external meatus, the inference is that the foot-plate is freely movable while the malleus and incus are fixed or hindered in their vibrations. If such is the case, a rational sort of treatment is at once suggested, i. e., either the freeing of the malleus and incus from the adhesions or other hindrances or removing one or both, perhaps, preferably only the incus. The sound waves might then reach the foot plate through the vibrations of the air in the tympanic cavity and hearing be materially improved.

A condition which has been but recently much spoken of in this country is known under various names, as "Spongifying of the Bony Capsule of the Labyrinth," "Multiple Sclerosis of the petrous portion of the temporal bone," "Rarefying osteitis of the petrous portion of the temporal bone, especially that part near the oval window." This condition was, I believe, first described by Bezold more than twelve years ago, but is best known by the writings of Siebenmann. Briefly, it is a rarefying osteitis of the petrous portion of the temporal bone, especially that part around the oval window. It begins chiefly between the ages of eighteen and thirty, with gradually increasing deafness, although it may progress in rare cases by leaps and bounds. It develops independently of middle ear disease, although both may be present in the same case. When spongifying is present alone, the case may be readily diagnosed by the absence of any objective signs of middle ear disease, and by the three signs as described by Siebenmann, namely, (a) increased bone conduction for fork A; (b) the loss of hearing for low tones, and (c) the negative Rinne.

In closing the writer wishes to say that he has found many of the foregoing tests of great value in making a differential diagnosis, and in estimating the probable course and termination of certain cases. Of course, in many cases all this can very well be done without such aids, but this fact does not minimize their importance, but rather sets them apart as of especial value in selected cases.

What seem to be numerous exceptions to the rule are, after all, neither numerous nor difficult to understand. This is true if they are studied in the light of well-known physiologic experiments, rather than as arbitrary exceptions to be remembered and used empirically.

A Severe Case of Anthrax Cured by Injections of 5% Carbolic Acid. W. A. Niemtschenko (*Voenno-meditsinski Journal*, 1900; *Meditsinskoie Obozrenie*, February, 1901,) reports the case of a man who developed a malignant pustule on the right cheek near the eye. The infiltration was great and the systemic manifestations severe. Injections of 10 $\frac{1}{2}$ springful of a 5% solution of carbolic acid into the affected region brought about a prompt subsidence of the alarming symptoms, resulting finally in complete recovery. The author states that while weak solutions of carbolic acid may cause poisoning from the absorption of the drug strong solutions have no such effect. [A. R.]

REPORT OF A CASE OF RUPTURE OF THE EYE-BALL FROM CONTUSION—LUXATION OF THE LENS. HERNIA OF THE IRIS AND CILIARY BODY.*

By J. W. SHERER, M. D.

of Kansas City, Mo.

On February 25th, 1901, D. N., married, art. 47, was referred to me by the courtesy of Dr. Coons. Patient was seen at midnight about an hour after having received a light blow on the outer side of the right eye with the tips of the fingers of the open hand of an acquaintance with whom he was having a friendly sparring match. When seen by me the tension of the eyeball was nil; the anterior chamber was completely evacuated; the pupil was distorted and displaced upward and inward; the pupillary space was narrow, elongated and extended to the limbus opposite a point where a rent in the sclera and conjunctiva showed the black mass of the iris and ciliary body protruding.

There was evidence of extensive hemorrhage into the interior of the eye-ball. The rupture was situated about three m. m. from the sclero-corneal junction and extended about 5 mm. in a line parallel with the same from 50° to about 80° from the horizontal in the upper internal quadrant of the globe. The rupture was slightly irregular and its edges somewhat serrated. The location corresponded accurately to what is described by T. Collins to be the typical place for scleral rupture to occur. According to Fuchs the rupture is most likely to occur 90° from the point where the disrupting force impinges upon the eye-ball. He bases his opinion upon the hypothesis of Arit, which is as follows: When a non-penetrating force is applied to an elastic globe, flattening of the globe occurs with the point of sharpest curvature at a right angle to the axis of the thrusting force. Thus if a blow fall directly upon the center of the cornea, the place of sharpest curvature, the place of greatest strain, and the most probable place of rupture, will be at the equator. Other theories have been advanced. One is that of rupture by contre coup at a point opposite to the point where the thrust is received. I do not think it possible that the eye ball can afford perfect exemplification of the physical forces and principles involved, but that, as in the present instance, the place of rupture is determined by the compound of all the opposing forces present. In other words the rupture will occur at the weakest place assailed by a sufficient strain. The eye is most liable to violence from in front and from the outer side.

I consider that it is peculiarly the very prominent, protruding eye which most frequently ruptures. This is vividly shown in this case. You will observe that the patient has very prominent eyes which have almost no bony protection whatever externally. This being the case the rupture will tend to occur in the upper and inner quadrant of the globe. The sclera varies in thickness. Its diameter of one m.m. posteriorly gradually diminishes anteriorly to the equator. In the zone just behind the insertion of the recti muscles which, as you know, is five to eight m.m. from the cornea, the diameter is .35 m.m. More anteriorly it is re-inforced by the tendinous insertions of the recti muscles, these becoming interlaced with and felt into the fibers of the sclera. Thus we would expect to find the weaker spots between the tendons. In fact it is here that nearly all ruptures occur.

Approaching the cornea the bundles of fibers become arranged so that there is a preponderance of those fibers which run in a circular direction parallel with the cornea. This explains the invariable extension of these ruptures in this direction.

On account of the late hour at which this patient was first seen, and because he did not wish to enter a hospital, it was deemed inexpedient to attempt more at the time than to asepticise the eye and apply a suitable bandage. Thus protected the patient was carefully conveyed to his home and placed quietly in the recumbent position. Next morning under the strictest aseptic precaution, after excising so much of the prolapsed viscera as could not be reposed, with a very fine sharp needle and very fine black silk the ruptured conjunctiva and episclera were sutured conjointly. The

*Read before the Kansas City Academy of Medicine, April 20th, 1901

importance of great care in securing asepsis will be better realized when it is remembered that the vitreous has very little power of resisting infection. In fact it possesses a number of qualities necessary to a good culture media for bacteria, including alkaline reaction which nearly all bacteria require.

The wound being closed, atropine was instilled, both eyes bandaged, a calomel and soda laxative given, the patient admonished to lie very quietly on his back, and to partake of no food except such as was light easily digested and required very little mastication. The patient was very obedient and contributed all in his power to gaining a good result. For several days the eye was aseptically treated twice daily; then when it was seen that there was no inflammatory reaction worth mentioning, once daily. On March 4th, the seventh day, the surgical dressings were removed. March 6th all blood had disappeared from the anterior chamber which was again established. The pupil was still occluded with blood clot.

The left eye was now left uncovered one hour in the morning and afternoon, and the patient permitted to use gentle exercise during these periods. March 14th the bandage was removed entirely. The tension of the eye was again normal. Smoked coquilles were advised to be worn with cotton behind the right lens, thus closing and protecting the injured eye. An uneventful recovery was thus secured. When the blood in the vitreous was absorbed a clear fundus was found. The lens was dislocated and a -10 D. lens in the ophthalmoscope gave the best view of the retina. On the nasal side there was an area of retinal detachment (ablation of retinae). The ophthalmometer showed 2.75 D. astigmatism with the rule and the best vision, 6-12, was secured with +10.00 s. +2.00 c. ax. 60°.

I wish to point out that incised wounds of the sclera frequently recover and that ruptures very rarely do. I have been able to find record of but three cases of bona fide ruptures, but feel assured that they occasionally occur. I have been unable to ascertain the percentage of recoveries, but systematic writers uniformly agree that these cases are uniformly lost. The violence done the organ of vision is best indicated by calling attention to the great fragility and delicacy of its internal mechanism.

The scleral capsule is tough and inextensible. Its contents are soft and easily disorganized. The attachment of the retina in its most vital part is so slight as to be almost elusive. The mesh-work which contains the vitreous fluid and makes it a body instead of a fluid is so exquisitely delicate that the finest gossamer filaments of silk that can float on a summer zephyr is as a ship's hawser compared to it. Imagine the pulpifying effect of a contusing blow sufficient to burst the eyeball by compressing its contents, as is always the case in a rupture.

In the present case not only the sclera, but the extremely elastic conjunctiva also was ruptured. The degree of vision saved in this case is three-sixths, or one-half of normal, which is considered successful for a cataract operation. But even after recovery is accomplished there are still elements of hazard in the sequel. The scleral cicatrix may become ectatic and a scleral staphyloma result. Cases are known where, by some occult means, infection has developed after many months and panophthalmitis has resulted.

Retinal detachment may occur from different causes, such as the violence of the blow, sub-retinal hemorrhage, loss of vitreous, and as a late sequel tension upon that part of the uvea connected with the cicatrix produced by cicatricial contraction. The danger of irido-cyclitis and glaucoma is not altogether phantasmal. That

bug-bear, or, as the Germans say, das Schreckensgespenst, sympathetic ophthalmia, is always within the horizon of the conservative surgeon when a dislocated lens is retained within the globe, as in this case. However, the danger is very remote, and the eye is likely to remain quiescent for years.

ANISOMETROPIA.

By NORBURNE B. JENKINS, M. D.,
of Chicago.

About half of the civilized have unlike eyes; one eyeball is different in shape from the other, and spectacles are required with the two glasses ground differently. This trouble is called anisometropia, and a study of it may show the general practitioner why many are unable to read five or six hours a day; why many needing proper glasses are wrongly supposed to have weakness of eyeball muscles; why some are fitted with glasses in a few minutes and others are never fitted; why the importance of fitting glasses is underestimated; why nervousness and headaches are so often unrelieved.

Farsightedness is the most common of all eye imperfections. Many with plain farsightedness have one eyeball flatter, smaller or shorter than the other; again, the two eyeballs may be alike and one focusing muscle stronger than the other. Such, at best, are often difficult to fit; at worst, when both focusing muscles and eyeballs are unlike, the difficulty is greatly increased. About one-third of the people have the same degree of farsightedness in each eye, and also have one focusing muscle just as strong as the other. These, sooner or later, need spectacles with two magnifiers exactly alike, and, as a rule, are easy to fit, often fit themselves in the stores. Sometimes one eye is more farsighted and has a proportionately stronger focusing muscle than the other, consequently, the eyes balance and unlike glasses may not be needed until late in life.

In most plain near-sightedness one eyeball is longer or larger than the other. Such are wrongly supposed to be more easily fitted than unlike farsighted eyes. Nearsightedness is the least common of eye imperfections, and is rare in some parts of the world and in savage and semi-civilized peoples.

A few have a nearsighted and a farsighted eye, and some of these read with one eye and see at a distance with the other.

In astigmatism the eyes are usually unlike, for, as a rule, one eyeball is imperfectly rounded either in a different location or to a greater extent than the other; often both the location and amount of the astigmatism are different in each eye. Astigmatism is almost as common as farsightedness.

About half of the people have farsightedness united with astigmatism in one or both eyes, and worse still, one or both imperfections is usually different in each eyeball, so most with both farsightedness and astigmatism have unlike eyes. While the shape of the two eyeballs is usually different in these cases, the size is frequently the same, consequently, if magnifiers are used, the average power of each glass is the same, an important guide in balancing such eyes.*

More than half of the nearsighted have astigmatism, and it is common for the amount of both imperfections and for the location of the astigmatism to be different in each eyeball. In nearsightedness united with astigmatism, one eye practically always requires a glass ground differently from the other, and, further, the average concavity of each glass is usually different.

Some have one eye about perfect, while the other is somewhat imperfect, or even deformed and practically useless.

There may be both farsightedness and nearsightedness in the same eye. This is mixed astigmatism. Such an eye may be perfect in size, but imperfect in shape, for an eyeball may be as much too broad across as too short up and down. Mixed astigmatism is somewhat common, and is easily mistaken for nearsightedness. The eyes are usually unlike in mixed astigmatism.

There are thirty-five combinations of unlike eyes. The two eyeballs tend to be the same size and shape, and even unlike eyes have this tendency. Eyes with less farsightedness, nearsightedness or astigmatism than O. 25 D, and not more unlike than O. 12 D, may be considered perfect. Only about one person in a hundred has such eyes.

In unlike eyes one focusing muscle gets weak prematurely. The difference in the strength of the two muscles is usually noticeable at the age of forty, while at the fiftieth or fifty-fifth year one of the muscles is often powerless. Sometimes one of the focusing muscles never develops whether the eyeball is perfect or not.

In unlike eyes, in time, the sight of one will be better than the other, still, with right glasses, the sight of each is alike. The slightest difference in the shape or size of the two eyeballs is easily discovered in the aged, for, if tried by holding a magnifier before one eye and then the other, fine print, held at reading distance, is more distinct to one of the eyes.¹ When indicated, a concave or a cylindrical glass may be used instead of a magnifier. The focusing mechanism in children is so powerful that slight degrees of unlike eyes are often impossible to detect. Belladonna may be used in the young, and the fine print test tried as above.

The worst results of unlike eyes are crosseye or squint, and its blindness and another blindness in which the eyes look all right even to the expert. Strange to say, a slight difference in the shape of the two eyes may cause these troubles, and worse still, it is usually the better shaped eye that suffers. In crosseye and cockeye the eyes are usually unlike in shape or size, and the strength of the two focusing muscles is always different.

About half of aged readers with unlike eyes have the full use of only one eye; the other has become more or less blind from suppression of retinal images and non-use.² This blindness comes from unlike eyes and lack of proper glasses. Every pair of peddlers' and store spectacles has the two glasses exactly alike, and cannot suit any unlike eyes, and so may cause this blindness which may come in unlike eyes unless glasses make fine print as distinct to one eye as to the other. If the aged use but one

eye, they are not particular about their glasses, just so they magnify too much.³

Three or four years ago refractionists thought all was known about correcting eye imperfections. Recent investigations show that more than half of the people have astigmatism, unlike eyes or both, and sooner or later have trouble in reading and in getting proper glasses. Astigmatism is easily overlooked in the most delicate tests, and is often confused with beginning amblyopia. It is often difficult to discover astigmatism, much less to determine its location and amount. Uncorrected or improperly corrected astigmatism causes more trouble to readers than all other eye troubles put together. Some read all day and others have pain and blurring after reading a few minutes. This difference comes from misshapen eyeballs and not often from weakness, as most believe. With the right spectacles, most with ill-shaped eyeballs can read about as much as those with perfect eyes. There is not enough known about fitting simple farsightedness and nearsightedness, and in complicated astigmatism and unlike eyes proper glasses are seldom or almost never obtained, for astigmatism is commonly overlooked or about half corrected. Correction of astigmatism is by far the most difficult problem and work in ophthalmology.

The standard text books contain remarkable statements about anisometropia. Different treatments are advised and theories given to support them. Some authorities say:

"With different glasses the two retinal images of the same object are different, and so cannot match one another, cannot perfectly superimpose, consequently, in unlike eyes, either give the same glass for both eyes, or correct only one eye and place a plane glass over the other." Others follow this:

"If the eyes are much unlike only the better one is used for vision; the other has not been used to clear images, consequently a glass which makes the sight normal will not be tolerated. In such cases the better eye should be fully corrected, and the worse eye should be partially corrected, fitted with a plane glass or given the same glass as that on the better eye."

People with eye imperfections amounting to deformity have never had good vision, yet these "tolerate" the clearest images if the right glasses are given. Those blind for years with cataract wear best glasses that give best sight. Many with eyes farsighted exactly alike, but with unlike focusing muscles, wear a different magnifying glass on each eye with perfect comfort. In an imperfect eye with a proper glass, and in a perfect eye, images are the right size. If "superimposing" amounts to anything, images of imperfect and unlike eyes ought to "superimpose" if glasses make them like the images of perfect eyes and make them both the same size.

If there is no disease and no deformity ametropia (astigmatism of more than 3.5 D, or farsightedness or nearsightedness of more than 7.D), there is nothing to prevent use of both eyes at the same time for reading or far vision, provided proper glasses are prescribed, each eye fitted right.⁴ The

2 Ophthalmic Record, February, 1900, page 88.

3 Journal A. M. A. May, 1899, page 1032.

4 Journal, A. M. A. February, 1899, page 351.

reasons given in the standard text books for these different treatments are wrong. If the sight of an eye can be helped, the sight should be made as near normal as a glass can make it, otherwise the retina and the focusing mechanism may suffer from non-use. In unlike eyes there is but one treatment, difficult though it be, and that is to fit each eye on its own merits. If this is properly done, the eyes balance, see alike and act in harmony.

One diopter of farsighted astigmatism affects the size of the eyeball the same as one-half diopter of farsightedness. The eyes tend to be the same size, and, if one eye, the right eye, has one diopter of farsightedness and one diopter of farsighted astigmatism, while the left eye has half a diopter farsighted astigmatism, then, it is usual for farsightedness of a diopter and a quarter to be in the left eye, when spectacles with the two glasses, each of the same average convexity, will be required. Typical eyes may further simplify: If the right eye requires: $+ O. 75 S. = + O. 50 C.$; $+ O. 50 S. = + 1. C.$; $+ O. 25 S. = + 1.50 C.$; or $+ 2. C.$ then, as a rule, the left eye will require one of these four glasses, or even a $+ 1 S.$ All these glasses make different images and yet the average convexity of each is the same.

Size, shape and position of the crystalline lens are not considered in this paper.

JOURNAL DES PRACTICIENS.

March 30, 1901. (15me. Annee, No. 13.)

1. The Evolution and Treatment of Strabismus in Young Children. ROCHON-DUVIGNEAUD.
2. The Choice of Catheters and the Difficulties of Catheterization in Hypertrophy of the Prostate. S. BAN-ZET.
3. Surgical Analgesia by Sub-arachnoidal Injection of Cocain through the Lumbar Spine. H. MILHIET.

1.—**Convergent strabismus** in children may be congenital, it may occur suddenly with convulsions, or it may develop gradually, as is most common, between 2 and 3 years of age. The majority of cases of congenital strabismus disappear spontaneously. The absence of diplopia will distinguish strabismus from oculomotor paralysis. Vision cannot be determined until the age of 4 or 5 years and it is then found unequal in the two eyes, the fixing eye having far superior sight. Most such children show hypermetropic astigmatism. The squinting eye early develops amblyopia from disuse. While these cases generally recover about puberty, the amblyopia persists. In some cases divergent strabismus may result later. Atropine should be used in the fixing eye, so that the other eye must act functionally, for the good eye will have its accommodation paralyzed. This should be dropped into the eye for the first three days of each week, or for two weeks, alternating with two weeks of rest. But after the age of 4, correcting glasses should be used. Refraction is done under atropine, and the glasses ordered for constant wear. To continue the use of the squinting eye, the fixing eye should be bandaged at noon for the rest of the day. This will prevent amblyopia from disuse, and neither the one eye nor the other will become the permanent fixing eye. When the child grows older, stereoscopic exercises, tenotomy, or advancement may effect a permanent cure.

[M. O.]

2.—In hypertrophy of the prostate, regular evacuation of the bladder by repeated catheterization is the ordinary palliative method of treatment. For this a Nelaton rubber catheter or a Mercier elbowed catheter can be used. The former is preferable for the patient's own use, and can be easily sterilized. When the former can not be employed, the latter may. But this is hard to sterilize. Many sounds

will be tried before the correct curve is found. Besides, the fact that the prostatic urethra may change its form must not be forgotten. A catheter that has passed easily will not then pass, or *vice versa*. More attempts will then be necessary with different catheters. [M. O.]

3.—For this new method of producing analgesia, a 1 or 2% solution of cocain is employed, in injections of $\frac{1}{2}$ to 4 cc. Large doses cause distinct after-effects. The solution, the needle, and the patient's back, must all be well sterilized. The punctures should always be made below the second lumbar vertebra, preferably in the third interspace. The patient should be sitting up, and the needle should be 9 or 10 cm. long. A few drops of cerebro-spinal fluid is allowed to escape, and then a full minute is given to slowly injecting the cocain. A collodion dressing is applied. Analgesia begins in the feet, and gradually rises higher. It is general in 10 minutes. It lasts from 20 to 50 minutes, depending on the dose of cocain injected. Nausea, vomiting, thirst, headache, tremulousness, and anxiety are the common after-effects. Headache, insomnia, and mental troubles may persist for some time afterward, with fever. As small a dose of cocain should be used as possible, and an injection of caffeine and morphine given before operation. Men bear it better than women. It should never be employed in children under 16 years, in nervous or alcoholic subjects, nor when a long operation is necessary, in which case chloroform is to be preferred. But this method is especially useful in the debilitated and the depressed, those affected with pulmonary or cardiac lesions, nephritis or arteriosclerosis, and in those who object to general anesthesia. [M. O.]

April 6, 1901. (15me. Annee, No. 14.)

1. The Psychic Equivalent of Epilepsy. P. RAYMOND.
2. Enteroptosis. FRANTZ GLENARD.

1.—In epilepsy, in place of the usual convulsive attack, motor, sensory, or psychic equivalents may occur. Or psychic manifestations may appear with or after an ordinary fit. In a girl of 19, the attack would come on as usual, but convulsions were limited to the pharynx. She made the motion of swallowing a few times, then was herself again, ignorant of the attack. Another had hiccough, with vertigo, and also loss of consciousness for a few seconds. Another whose aura was always great hunger, would lose consciousness after feeling hungry. Another had erotic sensations, became unconscious, rubbed her abdomen vigorously, and again became conscious. One felt very happy during her attacks; another showed sudden sadness; and another became very much frightened. One suddenly observed that her surroundings were strange, unknown to her, though she had seen them for months; another told a friend that he was pale, then fell unconscious himself. A certain word pronounced, an incomprehensible idea, a souvenir, will all cause these psychic attacks, with or without convulsions. More interesting cases are reported. [M. O.]

2.—**Enteroptosis**, descent of the intestines, has been considered a morbid entity since 1885. Glenard says that it may occur in four separate conditions, nervous ailments, dyspepsia, disease of the liver, or general constitutional illness. It is very common, four-fifths of the cases being in women. The symptoms will be many, pallor, a sad expression, complaints of feeling badly all over, loss of memory, of the power of concentrating attention, irritability, etc. Symptoms of all kinds exist, of indigestion, weakness, emaciation, etc., and no treatment will prove beneficial. Examination of the urine, blood, gastric juice, etc., shows everything normal. Physical examination will reveal tenderness in the epigastrium, with a marked epigastric pulsation, great diminution in the tension of the abdominal wall, and the transverse colon will be felt crossing the aorta, about the size of a cord, freely movable under palpation. The rest of the colon will also be palpable, the cecum alone being found of normal size. The right kidney may be movable, and the right lobe of the liver elongated, thin, and low down. These are the three main symptoms, a stenosis of the colon which lies low in the abdomen, movable kidney, and deformed liver. The sustaining ligaments of the viscera are relaxed, and gastroptosis, enteroptosis, nephroptosis, hepatoptosis, splanchnoptosis, finally, follow. An abdominal binder, correctly applied, will aid in the treatment. [M. O.]

\$3.00 PER ANNUM

The Therapeutic Monthly.—We are happy to announce the appearance of the first number of this new journal under the editorial charge of Professor Tyson, Dr. Coley and Dr. T. M. Tyson. In appearance it is not unlike the **Philadelphia Medical Journal**, and will constitute an important monthly companion to this journal for those of our subscribers who have availed themselves of the opportunity of obtaining it. There is not, of course, a more important field in scientific medicine than therapeutics, and the new journal will cover this field to the satisfaction of the active practitioner who wishes to keep himself and his practice fully abreast of the progress of the times.

The Proposed National Bureau of the Materia Medica.—The necessity of definite and concerted action on the part of the profession in order to regulate the introduction of new remedies of whatever class, may be regarded as one of the vital questions for discussion at the St. Paul meeting of the American Medical Association. Our *Materia Medica* stands in need of careful revision and cautious expansion. In the development of synthetic chemistry, with its tremendous possibilities in the field of treatment, we witness hundreds of products placed daily on the market, and to this class may be added the various "special formulæ" of well-known agents. The scientific work done in the well-equipped chemical laboratories of these firms is frequently of the highest order, and there can be little doubt that, as such, it is entitled to respectful hearing and full investigation. Along with the meritorious preparations are hosts of worthless ones duly proclaimed as of great value. The good and the bad alike are seeking endorsement. The question of the employment of proprietary products in general is a broad one. It is too vast in extent and importance to be ignored utterly. In this connection, we believe that the plan suggested by Dr. F. E. Stewart for the establishment of a National Bureau of the *Materia Medica* is a most excellent one in its general scope. It is Dr. Stewart's idea that such a Bureau should be empowered to examine carefully, and at length, the pharmacology of such new remedies as may be presented for its official sanction, as

well as to investigate the method of preparation, and by extended clinical trial determine the value of these new remedies. The duties of the Bureau would include the determination of a suitable method of standardization of all of the remedies of the *Materia Medica*. Its establishment would insure a greater amount of uniformity in our drugs, as well as supplying us with reliable information as to newly discovered products. This question was brought up at the recent meeting of the American Therapeutic Society in Washington, and a Committee was appointed to investigate the matter. This Society also took the initiative in the important matter of regulating the subjects to be discussed before it by passing unanimously the resolution declaring that: "Any therapeutic agent offered for discussion before the Society should be discussed under its chemical name, and not under its fanciful, patented, or copyrighted commercial name." It is our opinion that in this action the American Therapeutic Society has done a wise thing, and its example should be followed by medical bodies generally.

The Treatment of Sarcoma with Toxins.—Every practitioner of every branch of the medical profession must entertain an active interest in anything that pertains to the cure of that dread malady, sarcoma, and, therefore, we can commend to our readers the interesting account by Dr. William B. Coley, of the "Late Results of Treatment of Inoperable Sarcoma with the Mixed Toxins of Erysipelas and Bacillus Prodigiosus," to be found on another page of this issue of the **Journal**. This method of treatment, introduced a number of years ago by Bull and Coley, has suffered, as have so many other new methods, in having too much expected of it by the profession at large, even more than was claimed by its originators. Hence there has been considerable criticism of the treatment because it did not relieve *all* cases of sarcoma in which it was employed, and oftentimes not thoroughly employed. Coley, however, has not been discouraged, but has continued his interesting work and now gives us his results after a number of years have elapsed since the treatment was instituted, and they are such as to impress upon any but a con-

firmed pessimist, not only the advisability, but the necessity of using this treatment in certain forms of inoperable sarcoma. He shows the danger of the treatment to be practically nil, and only recommends it in inoperable cases. If he and other surgeons can produce an occasional cure by the use of the mixed toxins, as has certainly been done, then it becomes our duty to a patient suffering from an inoperable sarcoma to give this method a thorough and conscientious trial. The profession certainly owes to Coley a debt of gratitude for his careful and painstaking work in the treatment of inoperable sarcomata, where all our former methods have proved so absolutely hopeless.

Auto-Inoculation of Cancer.—As a contribution to the subject of the causation of cancer, Dr. A. T. Cabot reports (*Boston Medical and Surgical Journal*, May 16, 1901) an interesting case of what appears to have been an accidental inoculation of cancer in a fresh wound. The patient was a man who was suffering from cancer high up in the anterior wall of the rectum. A Kraske incision was made and the cancer dragged down into this opening and removed through it. During this manipulation the fluid from the cancerous growth was rubbed over the wound made by the Kraske operation. At the end of four years the cancer had not recurred at its original site, but two years after the operation a hardening of the tissues was noticed behind the rectum, at some distance, of course, from the site of the original growth. Cabot operated for this second growth, which was about as large as a hen's egg. On microscopical examination it was found to be an adenocarcinoma with colloid degeneration identical with the original growth. The scar in which the secondary growth took place was separated by an interval of five or six inches from the seat of the original growth. As Cabot points out, this is not a case of direct extension of the disease. The lymphatic vessels from the seat of the original disease run upward of the lumbar glands, and not downward toward the point of recurrence. This anatomical relation, together with the absence of any lymphatic structure in the recurring nodule, removes any suspicion of this having been a secondary growth in a lymphatic gland. It seems, therefore, that this was a transplanation of cancer; in other words, a true autogenous inoculation. The conditions were certainly favorable for such an event, as the cancerous growth, torn and squeezed by the forceps, was incidentally rubbed for several minutes on the fresh wound.

Dr. Cabot points out the practical importance of taking great care in the removal of cancer to avoid such a contingency. From a pathological, or we may say theoretical standpoint, the case is certainly

an interesting and apparently conclusive one. It was an accidental experiment, such, of course, as would not be justifiable intentionally in any patient, and therefore of unique importance.

The Presidency of the New York Lunacy Commission.—The State of New York is fortunate in obtaining the services of Dr. Frederick Peterson as President of the State Lunacy Commission, and Governor Odell is to be congratulated on such a wise and discriminating use of the appointing power. The Lunacy Commission of that State in recent years has not altogether succeeded in holding public and professional confidence. Its wrangle with the Pathological Institute was an instance that proved that it had not the wisdom at least to extricate itself and one of its charges from an embarrassing situation. Whatever the merits of that controversy may have been, the one fact that remains most apparent is that the trouble should never have been allowed to reach the acute and aggravated stage in which the public came to know it.

Dr. Frederick Peterson is admirably equipped to step in at this juncture and bring harmony to both the administrative and scientific work which is to be done under the general supervision of the Commission. He is well known as a scientist, and he is almost equally well known by reason of his work for the Craig Colony of Epileptics as a practical man of affairs. He will have great opportunities now to do good work, for the field in New York is a great one, and by reason of its importance and prominence is always looked to for initiative and good example. We think the occasion is also opportune to express confidence in a Governor who has already given many proofs that he believes it to be his business to govern.

A Psycho-Physical Laboratory.—Efforts are being made to induce the United States Government to establish a laboratory of this kind in the Department of the Interior. If properly equipped and conducted by competent students of psychology, such a laboratory would be of distinct service. The present cry of "degeneracy" for every aberrant and vicious display of human nature does not have our sympathy, and we could only endorse the founding of such a laboratory if we felt sure that it would be conducted on strictly scientific and critical lines, and not merely to exploit the theories and fads of inexperienced and visionary compilers. A vast field remains to be explored in psycho-physics, but it is a most difficult and involved one. To conduct the investigations which are to be the object of such a laboratory, will require the skill of men who have high natural and acquired attainments. Such talent can be commanded in most fields by the United

States Government much more easily than it can be found in psycho-physics, and it will behoove the authorities at Washington, if they consent to undertake this scheme, to recall constantly the fact that not only money, but also men, are required to equip a laboratory.

The Treatment and Prophylaxis of Rabies.—The department for the treatment of rabies, of the institute for infectious diseases in Berlin, was opened in 1898, on the recommendation of Dr. Robert Koch. In 1896 there was a marked increase in the number of cases of rabies in Berlin, from 66, the incidence in 1895, to 128, the incidence in 1896. In 1896 the mortality was 3.13%. In 1897, there were 161 cases, with a mortality of 3.11%; in 1898, 263 cases with a mortality of 3.42%; in 1899, 287 cases with a mortality of 1.05%; and in 1900, 384 cases with a mortality of 0.27%. These figures demonstrate that although the number of cases of rabies has steadily increased since 1896, the mortality since the opening of this department of the institute has fallen until it has reached the remarkably low percentage quoted. In Germany, the majority of cases of rabies occur near the Austrian and Russian boundaries (Public Health Reports). The infected animals wander over into Prussia and there spread the disease. In Germany, an animal is killed as soon as it shows the first signs of rabies; but it will be impossible to banish that disease from Germany until the neighboring countries take the same precautionary measures against its spread as Germany has taken. In Berlin proper, no case of rabies has developed since the passage of a law, in 1873, requiring the muzzling of all dogs during the entire year. The experience of the medical authorities in Berlin is that the decrease of danger during the winter months is not sufficient to cause the law to be relaxed during that time. In the institute for infectious diseases rabies is treated according to Pasteur's plan with, as figures show, most excellent results. This showing should completely set aside all captious criticism concerning rabies as a morbid entity and the efficiency of the Pasteur treatment as a therapeutic measure. The compulsory muzzling of dogs while on the public streets seems to us, on the whole, to be a wise measure. Fortunately, rabies is a rare disease in the United States, but there are many persons who would feel much easier if, when they met some of our huge canine friends, they could feel sure that the animals were incapable of doing harm.

A Review of the History of Cardiac Pathology.—Dr. Alfred Stengel delivered an address before the Wisconsin State Medical Society on June 21, 1900, which was published synchronously in the *Univer-*

sity Medical Magazine and in the *Philadelphia Medical Journal*, on "A Review of the History of Cardiac Pathology with Especial Reference to Modern Conceptions of Myocardial Disease." In this valuable contribution to medical literature an excellent review of the history of this subject is given from the time of Galen, whose doctrines on pathology were taught for many centuries, and to whom is credited the first suggestion of the possibility of cardiac disease, up to the early part of the nineteenth century. Stengel outlines the many important events leading up to the knowledge upon which are based our modern conceptions of this subject, especially emphasizing Harvey's brilliant achievement, the demonstration of the circulation, the learned classifications established by the distinguished French physician, Corvisart, the important observations of Bouillaud on valvular disease, the valuable methods of physical diagnosis contributed to medical science by Auenbrugger and Laennec, and the later writings on cardiac diagnosis by Hope, Testa, Burns, and Kreysig. Accurate knowledge of myocardial disease had its origin about the middle of the nineteenth century, and was largely the outcome of careful and painstaking study by Gairdner, Weigert, Bamberger, Hasse, Rokitsansky, Bochkalek, Dittrich and Virchow. The names of Allbutt, Myers, Seitz, and DaCosta stand foremost amongst those who have added to our store of clinical knowledge.

The author states that experience and statistics indicate that circulatory diseases are on the increase. At the present day our efforts must be directed to determine the causes of one of these problems, namely, myocardial weakness and degeneration. Of great interest is the statement that troubled times and general unrest of mankind probably play a most important causative rôle. During the revolution of 1830 in France, and during the revolt in Italy in 1848, and in Sicily in 1860, there was an increase in the number of cases of heart disease.

In an account of the clinical considerations of myocardial disease Stengel alludes to some of the early symptoms which should attract attention, particularly loss of physical activity, a disposition to be less interested in affairs, and a peculiar yellowish pallor of the face with slight prominence of the venules. Often after sudden fright there occurs a distinct change of color which may persist for an unusually long time. Somewhat later manifestations are weakness and irregularity of the pulse, and a relaxed condition of the skin accompanied by sweating. The author is convinced, from his own clinical observations, that a changeable character of the specific gravity of the urine is a sign which exists in many cases of myocarditis combined with

arteriosclerosis. Gastric phenomena, especially gastralgie attacks, the probable explanation being a deranged nervous association, he regards as early signs.

Dr. Stengel believes that if myocardial disease can be recognized early the progress of many of these cases may be arrested. A positive diagnosis, however, is usually impossible until the disease has become incurable, and for that reason he has directed attention to the earlier signs.

Protection from the Malarial Mosquito in Italy.

—Assistant Surgeon J. M. Eager writes from Naples, Italy, to the Surgeon General of the Marine Hospital Service, that prophylactic measures are being taken on the railroads of that country for the protection of employes from the attacks of mosquitoes. Extensive areas of fertile land in Italy are almost wholly deserted in the malarial season. The shepherds who feed their flocks on these lands in winter go to the higher country in summer. The few peasants who are forced to remain behind go to the higher lands every night to sleep. But railroad employes must remain at their posts, and they form a class of fallow, fever-smitten men who have for a long time been a sorry sight to railroad travelers in Italy. The railroad companies now propose to furnish them protection as far as possible. Wire gauze is supplied, and the windows and doors of station houses are screened. Switch houses are made of wire gauze, and whole verandas of like material are built. Head-covering, similar to that used in America by men handling honey-bees, is provided for employes who are obliged to expose themselves. Special material, supposed to be impenetrable to mosquito bites, is supplied for clothing. Surgeon Eager does not express any skepticism about the efficacy of these measures, but we should suppose it would be difficult to have the average Italian workingman adopt such precautions. We know from personal inquiry that it is not easy to induce the American workingman to observe common-sense precautions, as, for instance, in lead factories, grinding establishments, etc. If the Italian workingman at home is more reasonable than the American in such matters, it is more than can be said of him when he comes to this country.

Dr. Eager says that not much is to be expected from drainage and the use of petroleum in ridding the Roman *campania* of the mosquito pest.

The Control of the Venereal Diseases.—There is now being undertaken in Greater New York the first systematic attempt that has been made to collect statistics of venereal diseases.—a large but neglected class of affections which have a most important relation to the public health. We

wish to call editorial attention to this work and to urge a general response upon the part of the medical profession in the metropolis. The work is under the supervision of the Committee of Seven, of which Dr. Prince A. Morrow is chairman, which has recently been appointed by the Society of the County of New York. A resolution empowered the President of the Society to appoint this Committee for the study of the most practical kind of Municipal and State legislation to repress or control prostitution with a view of reducing the morbidity and mortality of venereal diseases. The Committee seeks for information from every practitioner and every dispensary as to the number of cases of gonorrhea and syphilis treated. It is especially desirous of gaining the fullest possible information relative to the prevalence of syphilis *in-sontium*, of gonococcic infection in marriage, and of venereal diseases occurring in children. This is a most important subject, and we trust this investigation will result in the institution of some practical method of controlling the terrible ravages of the venereal diseases. We published recently, as will be remembered, a most instructive paper on this subject by Dr. Morrow.

Correspondence.

ERYSIPELAS IN ASIA

By CLARENCE D. USSHER, M. D.,
of Van, Turkey, Asia.

Editor Philadelphia Medical Journal,

Dear Sir.—

The Philadelphia Medical Journal has been a helpful and welcome friend since its second volume. This help I have received has led me to pass on a few items which have been helpful to me during the past two years.

First, a treatment for erysipelas. I have been through three fairly sharp epidemics besides the ordinary run of a medical missionary's practice. I cannot say how many cases I have treated, but probably more than 150. First I used equal parts of jaborandi and iron internally and externally, an idea learned from Dr. A. M. Wilson, of Kansas City, Mo. Then I tried bathing with hot water and painting with ergot. Then a combination of the two treatments with moderate success. Finally, knowing that the streptococcus of erysipelas was quickly destroyed by even weak solutions of bichloride of mercury I began to figure on getting it into the tissues. With Dr. C. S. Merriam's suggestion of hot bathing as a starter, I ordered bathing for an hour with water kept as near the boiling point as could be borne, followed by an application of 1-500 bichloride solution for 20 minutes, to be repeated four times. The erysipelas had disappeared by next morning. I have since modified it to 1-1000 solution, used after $\frac{1}{2}$ an hour bathing. Two applications generally sufficing, though in severe cases I ordered four, the last one followed by yellow oxide of mercury salve, 8 grs. in one ounce of vaseline. The only fatal case was one in which the disease had

reached the brain before I was called on the 8th day of the disease.

Among your therapeutic notes last year was a mention of creosote and olive oil rubbed into sides and chest as ideal treatment for malaria in children. My experience confirms it with this important point to note that "beech-wood" creosote acts perfectly, but synthetic creosote (Merk's and others) has given me absolutely negative results.

Antisymphilitic "mixed treatment" combined with iodide of potassium in progressive doses up to point of toleration works well in both tubercular and anesthetic forms of leprosy. One patient required $25\frac{1}{2}$ drams of a saturated solution daily to produce effect. 27 drams (1620 grains) produced marked coryza and pain in the limbs, but no eruption or pytalism. $25\frac{1}{2}$ drams caused no unpleasant effects. Is there any record of a larger dose being tolerated?

Reviews.

International Clinics.—A Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose, and Throat, and Other Topics of Interest to Students and Practitioners. Edited by Henry W. Cattell, A. M., M. D., Philadelphia, U. S. A., with the Collaboration of John B. Murphy, M. D., of Chicago; Alexander D. Blackader, M. D., of Montreal; H. C. Wood, M. D., of Philadelphia; T. M. Rotch, M. D., of Boston; E. Landolt, M. D., of Paris; Thomas G. Morton, M. D., and Charles H. Reed, M. D., of Philadelphia. Volume I. Eleventh series, 1901. Philadelphia. J. B. Lippincott Company, 1901; price in cloth, \$2.00; half-leather, \$2.25.

This volume of the International Clinics is most excellent from cover to cover. Its contributors are widely known, and the subjects treated are of great general interest. We might mention especially the chapter upon: "Nervous Diseases and Psychoses following the Grippe," by William Broadus Pritchard; and that upon: "Sacculated Pleurisy, Bronchial Pneumonia, Anemia, Pernicious Anemia," by Francis Delafield, and the "Report of 100 Cases of Aortic Aneurysm with Details of Three Cases of Aneurysm of the Basilar Artery," by H. Batty Shaw, M. D. The chapter upon "Laboratory Methods," dealing with some practical methods in photomicrography, by W. H. Walmsley, is replete with excellent suggestions and accompanied by beautiful lithographs of his work. Edward Jackson contributes a chapter on "Points in the Diagnosis of Iritis and Glaucoma." This article will command the respect and attention of those interested in ophthalmology. Dr. A. Doleris treats of "Obstetrical Analgesia, Obtained by Cocain Injections into the Lumbar Arachnoid." On account of the present prominence of this subject this conservative article will be read with interest. Dr. A. A. Stevens has written a chapter on "Notes on New Remedies," which is comprehensive, progressive, and yet conservative. The work closes with a review of the progress of medicine during the year 1900 by Dr. N. J. Blackwood, U. S. N. In the department of therapeutics, this somewhat overlaps Dr. Steven's more thorough contribution, but this was scarcely to be avoided. We cannot do better in closing this brief review than to mention the chapter by Professor H. Hallopeau on "The Treatment of Eczema." It is pleasure to be able to commend this volume, both on account of the excellence of its subject matter, and as a good example of high-class book making. [T. L. C.]

Saunders' Medical Hand-Atlases. Atlas and Epitome of the Nervous System and its Diseases.—By Professor Dr. Chr. Jakob, of Erlangen. From the Second Revised German Edition. Edited by Edward D. Fisher, M. D., Professor of Diseases of the Nervous System,

University and Bellevue Medical College, New York. With 83 plates and copious text. Philadelphia and London: W. B. Saunders & Co., 1901. Cloth, \$3.50 net.

This authorized translation from the second revised German Edition is a useful work in the field which it covers. The plates are beautifully executed, and are copious enough to be of great value to the student. The diagrammatic interpretation of each plate is given upon the page facing it so that even those unfamiliar with the histology and pathology of the nervous system can readily observe the features to be pointed out. We find in this volume of 218 pages, 84 plates, and their excellence leaves but little to be desired. The work is considered under the following heads: First, Morphology of the nervous System, and in this chapter 14 plates are included; second, The Development and Structure of the Nervous System, Ontogenesis and Histology of the Nervous System, which is illustrated with 38 plates; third, the Anatomy and Physiology of the more important Nervous Pathways; the three plates accompanying this part are excellent diagrammatic explanations of the nervous pathways, done in color, and will greatly aid the student in mastering the intricacies of the subject. The General Pathology and Treatment of Diseases of the Nervous System follows. This is an important chapter, and in it are given the etiology of nervous diseases with plates of many of the pathologic alterations observed, as well as symptomatology and topical diagnosis of nervous diseases. Special pathology and treatment is handled with rare conciseness and yet admirable clearness. While of course in a work of this limited size the text is in no sense complete, yet it is wonderfully comprehensive, and is enlightened by the beautiful and artistic illustrations. The book closes with some general remarks on autopsy technique and the microscopic examination of the nervous tissues. We know of no one work of anything like equal size, which covers this important and complicated field with the clearness and scientific fidelity of this hand-atlas. [T. L. C.]

The International Medical Annual, A Year Book of Treatment and Practitioner's Index. E. B. Treat & Co. New York and Chicago. Price in cloth \$3.00.

This is the 19th edition of Treat's well-known Medical Annual. It has some especial features which deserve mention. The chapter on Toxins and Antitoxins is the work of Joseph McFarland and William Murrel, and the latter has also contributed a special article on the Light Treatment. X-Ray Work in Medicine and Surgery, is from the pen of Dr. Macintyre, of Glasgow. Dr. Eldridge-Green has written the chapter on Color Blindness; and Mr. Turner, F. R. C. S., is the author of that upon Dental and Oral Surgery. Professor Ruata, of the University of Perugia, Italy, has contributed the article on Tuberculosis. The dictionary of new treatment covering the whole range of medicine and surgery makes the work one of great value and convenience as a book of reference. That part of the work dealing with pharmacology in general should be found of interest considering the multiplicity of new drugs and the difficulty which at present confronts physicians in the effort to find out precisely what chemical combinations many of these preparations, sold under trade-names, really contain. We believe that the subject of organo-therapy has received less than its share of consideration. The work as a whole is of unquestioned value, and this 19th consecutive volume bears witness to the fact that its merits have been appreciated. [T. L. C.]

An Early Diagnostic Sign of Phthisis.—At the recent meeting of the Congrès des Sociétés Savantes, (*Revue Médicale de l'Est*, 1901, No. 8.), at Nancy, Dr. Finck, of the French Army, reported the fact that 20 c.c. of normal salt solution, injected into an individual in whom pulmonary tuberculosis is suspected, will cause marked febrile reaction in the nine hours succeeding the injection. This will occur in tubercular patients without fever, at the beginning of invasion, or after the process has developed. On the contrary, non-tubercular individuals will show no fever at all after injection. Should the reaction occur, the diagnosis of tuberculosis may be made with almost absolute certainty; if no fever occur, tuberculosis may nevertheless exist. [M. O.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

College of Physicians.—Abstract of the monthly report of the Honorary Librarian, Library of the College of Physicians of Philadelphia, April, 1901:

Books, pamphlets and journals received:

General Library: 447 volumes. 806 pamphlets. 3415 journals

Lewis Library: 11 " 0 " 0 "

S.D.Gross Library: 1 " 0 " 0 "

459 806 3415

Accessions, 378 volumes. Duplicates, 81 volumes

Donors, General Library, 67.

The College has acquired, by purchase, the valuable and perhaps unique collection of books and pamphlets known as the "J. Stockton Hough Library." About three thousand volumes, valued at eight thousand dollars.

Dr. Aloysius O. J. Kelly, instructor in clinical medicine in the University of Pennsylvania, recently was elected professor of the theory and practice of medicine in the University of Vermont. He leaves Philadelphia shortly for Burlington to begin his professorial duties, but he will return to Philadelphia in the early fall.

The Kensington Hospital for Women.—During the month of April seventy-four patients were under treatment. There were thirty-five patients in the Hospital April 1st, and thirty-five are under treatment at the present time. Nineteen sections and fifty-two other operations have been performed. In the Dispensary there have been thirty-nine new patients, who have paid one hundred and forty-nine visits.

Medical Society of the State of Pennsylvania.—The meeting of the Medical Society of the State of Pennsylvania in Philadelphia will be changed from September 17-18-19 to September 24-25-26.

Philadelphia Polyclinic.—Dr. Ralph Zeiss, who has been Professor of Diseases of the Ear for 17 years at the Philadelphia Polyclinic, has resigned his position and has been succeeded by Dr. Francis R. Packard, the present Dean of the Institution. Dr. Packard's place will be occupied in the fall by Dr. Randolph, of Richmond, Va., who is at present abroad studying Pathology. Dr. Randolph on his return will also take charge of the Pathological Laboratories.

Nathan Lewis Hatfield Prize.—The Committee on the Nathan Lewis Hatfield Prize, for original research in Medicine of the College of Physicians of Philadelphia has awarded to Prof. H. F. Harris, M. D., of Atlanta, Georgia, the sum of Five Hundred Dollars for an original research, conducted at the instance of the Committee, entitled: "A Study of the Alterations produced in the Large Intestines of Dogs by the Amoeba Coli, by Heat, and by Various Chemic Substances, with Notes on the Anatomy and Histology of the Viscus."

College of Physicians of Philadelphia: Section on Gynecology.—At the meeting of May 16, Dr. Charles P. Noble reported 3 cases. (1) A case of appendicitis complicated by diabetes and nephritis. The patient was 26 years of age. The sugar averaged about .75% but reached at one time 1.66%. The operation was performed under ether and recovery was good. This is the fourth case operated upon by Dr. Noble, when glycosuria was present. Three made good recoveries and 1 died of diabetic coma. Dr. Noble concludes that a moderate degree of glycosuria is not a positive contraindication to operation; (2) Hemorrhage following abdominal section. Hemorrhage occurred in this case because of the retraction of the uterine pedicle. This is the only case of secondary hemorrhage for 11 years, during which time 1275 abdominal sections have been made. Dr. Noble ligates the ovarian artery and the anastomosing branch between ovarian and uterine, when removing tube and ovary. Silk and catgut ligatures have given equally good results; (3) A cyst of inflammatory origin anterior to the uterus—a sequel of hysterorrhaphy. Dr. C. H. Judd reported conclusions based on 850 cases of etherization. He finds that ether is safe in any compensated heart lesion. He employs oxygen in every case and

uses a gauze inhaler. The time for inducing anesthesia varies between 10 and 15 minutes and the amount of ether from 1 to 2 ounces. Dr. Baldy said that every institution should have a pad anesthetizer and internes not allowed to give anesthetics. To become a good etherizer requires skill and training as well as to become a good operator. He prefers the Allis inhaler, gauze being bad in the hands of the ordinary anesthetizer. The finger should never be put in the patient's eye to determine the reflexes. Tongue forceps are very seldom needed, their use in the majority of cases being caused by faulty etherization. The majority of cases of pneumonia following operation are due to the ether and most such patients have been black in the face or giving trouble during the anesthesia. Dr. J. C. DaCosta said it was desirable to have a regular etherizer, but he had seen some unfortunate results under an expert anesthetist. He generally had better results from trained hospital residents, as his experience is that they are generally good etherizers. He always used oxygen after etherization.

Dr. H. D. Beyer read a paper on **Conservation of the ovary and functioning uterine tissue in the operation for hysteromyomectomy**. This refers to cases of myoma where the uterus is involved and the ovaries are normal. In such cases he leaves one or both ovaries and amputates the uterus as high up as possible. This prevents the artificial menopause. Cases were cited to show the good results of this procedure.

NEW YORK.

Medical Society of the State of New York.—At the 95th Annual Session of the Medical Society of the State of New York, held at Albany, N. Y., January 29th, 30th and 31st, 1901, it was moved and unanimously adopted that in order

to increase the facilities for becoming permanent members of the State Society, each County Society should be allowed to send five times the number of delegates it had formerly sent. These delegates are elected for a term of three years, and are eligible for permanent membership when they have registered at two Annual Meetings. This will make the number of delegates sent by county societies 750 in all, or one delegate for every eight or nine members of county societies, without increase in expense to the county societies.

It was further agreed, in response to a widely expressed desire, that the Society hold a semi-annual meeting in the city of New York in the early autumn, to be devoted entirely to scientific work and to social intercourse. The officers of the State Society announce that they have engaged the New York Academy of Medicine for this meeting, which will be held October 15th and 16th, 1901. Members wishing to read papers are requested to communicate with Dr. Nathan Jacobson, Chairman, Business Committee, 430 South Salina St., Syracuse, N. Y., and information of any other nature can be obtained of Dr. Frederick C. Curtis, 17 Washington Ave., Albany, N. Y., or of Dr. Frank Van Fleet, Associate Secretary, 63 East 79th St., New York City. It is further announced that the Society will tender a reception to its members, delegates and guests, at Delmonico's, on the evening of October 15th. Tickets to this reception will be furnished without cost to all who register at this meeting, and to the society's guests.

Smallpox has broken out about four miles from Poughkeepsie, N. Y. The victims are colored people, one of whom is thought to have brought the disease from New York City two weeks ago.

The New Mount Sinai Hospital.—The corner stone of this magnificent structure was laid on May 22 in the presence of the Governor and representatives of the Municipal Administration, with the most imposing ceremonies. The estimated cost is \$1,335,000. A more detailed account of the ceremonies will be published in the next issue of this Journal.

Insurance Against Malpractice Suits.—A New York insurance company proposes to insure medical practitioners against losses by malpractice suits. It bases its action upon the assumption that when it becomes generally known that physicians, surgeons and dentists are thus protected, there will be less inclination than there is at present on the part of speculative lawyers to bring such actions against members of the profession.

(From our Special Correspondent.)

American Congress of Tuberculosis in joint session with the Medico-Legal Society. May 15th and 16th, 1901.—The initial session of the Congress was held on the morning of May 15th, Dr. A. N. Bell, of Brooklyn, in the chair on behalf of the American Congress of Tuberculosis; Clark Bell, of New York, presiding on behalf of the Medico-Legal Society.

The introductory paper on "Legislation and Tuberculosis" was read by Clark Bell, who referred to tuberculosis as being rightly considered the most prominent sanitary question of the day. The presence of delegates from far and wide—from our various States, from the Canadas, from the South and Central Americas—attested the fact. The questions which the Congress were to consider were summarized as follows: Is tuberculosis an infectious or communicable disease? How far can legislation avert it, framed with a view of arresting the spread of the disease, by regulations, the enforcement of which would result in diminishing the facilities for its communication from one person to another?

In discussing the paper, Dr. E. P. Lachapelle, of Toronto, said that he advocated certain legislative measures, to wit: Compulsory notification, compulsory disinfection of dwellings after the death of a consumptive, the proper regulation of the cubic space in buildings, the exclusion of all cows presenting tuberculosis of the udder, fixing a minimum air space for cow-sheds. In addition, co-operation of the public by education in the schools, by conferences and by the distribution of suitable literature and the multiplication of sanatoria would be desirable measures.

Dr. G. B. Johnson, of Richmond, Va., said the keynote of the question was education; that the best way of educating the masses was through the formation of associations in each community for the purpose of discussion of the subject and the dissemination of the correct ideas through

the medium of the press. In this way, the knowledge of what constituted preventive measures would be spread. Dr. V. Havard (U. S. Army) recommended that the States found sanatoria where the afflicted might be induced to go, and where they might be treated, either gratuitously or according to their means. Patients wishing to remain at home should observe prescribed regulations and be subjected to official inspection.

Dr. J. H. Pyror, of Buffalo, dealt with the question of the care of the consumptives in the State of New York. He deplored the fact that the State did not offer to take care of them until the sufferers were in the last stages—when it was too late. In the State there were 14,000 deaths annually from tuberculosis, aside from the question of humanity, and viewed entirely as an economical one, the State could much better afford to take care of the 60,000 afflicted with tuberculosis—as soon as the diagnosis was made—than to harbor the 14,000 dying ones. Legislation, Dr. Pyror said, must move with education. It would not do to wait until the last man was educated before insisting upon the passage of certain measures beneficial to the public health. In other words, it is absolutely necessary to compel certain things. We do know a few facts about tuberculosis: It is communicable, it is preventable, it is curable if taken in hand early enough. Under these conditions, it is the duty of the State to help the sufferer, not as is done today, when it is too late, but in the early stages when the afflicted can be made well. The mission of the State Sanatoria is three-fold: To treat the individual, to protect the community, to educate the people.

Dr. A. N. Bell read a paper entitled "The Prevention of Tuberculosis," dwelling at length on the part the veterinarian plays in this respect, and emphasizing the importance of the public inspection of the milk supply in all its details. In the discussion of this paper, Dr. W. B. Husted severely criticised the U. S. Government tuberculosis test for cattle as being quite inadequate in not furnishing the proper control tests.

Dr. C. F. Ulrich, of Wheeling, W. Va., in a paper entitled "Suggestions for the Prevention of Tuberculosis" rather startled the delegates by his reference to the treatment of confirmed consumptives. "In regard to confirmed consumptives, who have passed the years of childhood and for whom there is no hope for recovery, with nothing before them but a life of misery, I am going to say something that may be stigmatized as unfeeling and cruel. But on the principle of the greatest good to the greatest number, I regard the idea as humane. I do not refer to what was at one time advocated by many physicians under the title of 'Euthanasia,' because in this age of exaggerated humanity, it would not be permitted even if its general benefits to mankind were proved beyond a shadow of a doubt. What I wish to suggest is this: In every case of confirmed and hopeless tuberculosis, desist from all efforts to prolong life, devoting your entire energy to making your patient as comfortable as possible even if the means employed should have a tendency to shorten life. For if you lengthen out the span of a miserable existence, permitting the unhappy being to marry and send out into the world an infected progeny, to increase the aggregate of suffering in geometric progression until the earth is filled with pale, emaciated, unhappy, useless, life-marring men and women, do you feel you have accomplished a humanitarian work?"

A paper "On the Curing of Tuberculosis in Sanatoria," by Prof. Schrotter, of Vienna, was read by proxy. In the paper, the writer urges greater care in the compilation of statistics. Only cases which can positively be considered such, ought to be enumerated as cured and all cases where treatment in the sanatorium failed should be made the object of special study and special analysis. In the medical reports of the sanatorium at Alland, near Vienna, great care is made of the use of the term "cured;" most cases are discharged as improved or relatively healed. If possible, cases are kept under observation for years, so that the real outcome of the case may be watched and recorded. Patients are required to present themselves for examination regularly at either the sanatorium or at the central bureau in Vienna; there subsequent examinations are made by the same physicians who admit the patients. Comparisons with the written histories are thus possible and reliable statistics of positive cures can thus be obtained.

Papers by title were read as follows: "Prevention of

Tuberculosis," by Dr. E. Liceagua, of City of Mexico: "Treatment of Tuberculosis," by Dr. G. W. Brown, of Atlanta, Ga.: "A Contribution to the Surgical Treatment of Tuberculosis," by Dr. J. B. Socasa, of Nicaragua; "The Bacillus of Tuberculosis," by Dr. H. W. Mitchell, New York; "Transportation of Tuberculous Passengers," by Dr. G. Chaffee, Brooklyn.

Dr. Henry D. Holton, of Brattleboro, Vt., was elected President; Dr. A. N. Bell, of Brooklyn, the retiring President. He was elected Honorary President. The following were elected Vice-presidents: T. D. Crothers, M. D., Hartford, Conn.; C. K. Cole, M. D., Helena, Mont.; Col. E. Chancellor, M. D., St. Louis, Mo.; A. P. Grinnell, M. D., Burlington, Vt.; A. E. Osborne, M. D., Glen Ellen, Cal.; U. O. B. Wingate, M. D., Milwaukee, Wis.; Wm. Bayard, M. D., St. John, N. B.; W. L. Bullard, M. D., Columbus, Ga.; Henry B. Baker, M. D., Lansing, Mich.; Raley Husted Bell, St. Louis, Mo.; J. Mount Bleyer, M. D., New York City; Prof. Thos. Bassett Keyes, M. D., Chicago, Ill.; Dwight S. Moore, M. D., Jamestown, S. Dak.

The session of the Congress was brought to a close with a dinner held on the evening of May 16, at the Hotel Majestic.

WESTERN STATES.

Emergency Outfits in Mills.—Factory Inspector Moersch, of the State Labor Department of Minnesota, is endeavoring to place surgical emergency outfits in all mills, factories and shops of the State where there are many employees.

The *Northwestern Lancet* states that the Iowa State Board of Medical Examiners has refused to recognize diplomas from Barnes Medical College of St. Louis as entitling their holders to enter the examinations of Iowa.

The Fiftieth Anniversary of the invention of the ophthalmoscope will be commemorated at the meeting of the American Medical Association at St. Paul next month.

Arkansas Medical Society.—The Arkansas Medical Society, at its last session, beginning May 14, and lasting three days, elected the following officers: President, F. Vinsonhaler, Little Rock; first vice-president, C. R. Chennault, Helena; second vice-president, W. N. Yates, Batesville; secretary, J. B. Runyan, Little Rock; treasurer, R. C. Thompson, Pine Bluff.

SOUTHERN STATES.

A Bill has passed the legislature of Florida, making four successive years of insanity on the part of husband or wife a ground for divorce. The party obtaining the divorce must provide for the maintenance of the divorced party.

Clinical Society of the District of Columbia.—On Tuesday evening, May 28, 1901, the Clinical Society of the District of Columbia will give its annual banquet. An elaborate programme has been prepared by the Committee, of which Dr. W. M. Barton is Chairman, and Drs. Wells, James, Ramburgh and De Vries the other members.

The Baltimore County Medical Association has elected the following officers: President, Dr. J. F. H. Gorsuch; vice-president, Dr. R. Percy Smith; recording secretary, Dr. W. P. E. Wyse; corresponding secretary, Dr. R. C. Massenburg; treasurer, Dr. H. S. Jarrett; executive committee, Drs. H. B. Stevenson, J. E. Bensen, Charles I. Hill; committee of honor, Drs. William J. Todd, L. Gibbons Smart, B. F. Bussey; historical committee, Drs. Jackson Piper, H. L. Naylor, William J. Todd; medical jurisprudence, Dr. Charles G. Hill, Dr. P. F. Sappington and Judge N. Charles Burke.

The *Washington Star* states that the Commissioners of the District of Columbia have received from the controller of the treasury an opinion on the question raised by the auditor of the District as to the compensation which should be allowed to the visiting physicians of the Washington Asylum and the police surgeons for examining suspected lunatics. Both the visiting physicians and the police surgeons are salaried officers. The Act of Congress regulating admissions to the Government Hospital for the Insane provides that two physicians shall certify as to the lunacy of the patient, and that each shall be

compensated at the rate of \$10 per diem for his services. It often happens that the examining physicians in lunacy cases are the visiting physicians and police surgeons, and the question raised was as to whether they were entitled to double pay in the premises. The controller decides that the physicians are entitled to pay in both instances, saying that their duties in connection with the two services are entirely separate and distinct.

The National Association for the Study of Epilepsy and Care of Epileptics, was held in conjunction with the Conference of Charities and Correction at Washington, D. C., on May 14th.

Changes in the Medical Corps of the Navy for Week Ending May 18, 1901:

MEDICAL DIRECTOR J. C. WISE, appointed a member of a Board for the physical examination of candidates for appointment to the Naval Academy.
P. A. SURGEON W. B. GROVE orders appointing him member of the Examining Board at Annapolis, reached.
SURGEON O. DIEHL, detached from the Indiana, and ordered to the Philadelphia Navy Yard.
SURGEON C. BIDDLE, detached from the Philadelphia Navy Yard, and ordered to the Indiana.

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine Hospital Service for the 7 days ended May 9, 1901:

H. W. AUSTIN, surgeon, to proceed to Washington, D. C. for special temporary duty—May 2, 1901.
R. M. WOODWARD, surgeon, granted leave of absence for 10 days from May 7—May 17, 1901.
W. G. STIMPSON, passed assistant surgeon, to proceed to Coal-gate, I. T., for special temporary duty—May 4, 1901.
TALIAFERRO CLARK, assistant surgeon, granted 30 days' extension of leave of absence, on account of sickness, from April 2—May 3, 1901.
D. E. ROBINSON, assistant surgeon, to proceed to Port Townsend, Wash., to assume command of station and report to the medical officer in command for special temporary duty—May 6, 1901.
DUNLOP MOORE, assistant surgeon, that portion of Bureau order of April 25, 1901, appointing Assistant Surgeon Moore to proceed to San Francisco, Cal., revoked—May 6, 1901.
L. W. RYDER, hospital steward, granted leave of absence for 15 days from May 6—May 7, 1901.

Official list of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine Hospital Service for the 7 days ended May 16, 1901:

JOHN GODFREY, surgeon, upon being relieved by Surgeon J. J. Kirtland, to proceed to Washington, D. C., and assume command of the service, relieving Surgeon T. B. Perry—May 11, 1901.
EUGENE WADSWORTH, surgeon, to proceed to Gardner, Ill., for special temporary duty—May 11, 1901.
Bureau order of May 14, 1901, directing Surgeon Washburn to proceed to Philadelphia, Pa., revoked—May 14, 1901.
T. B. PERRY, surgeon, upon being relieved from duty to Wilmington, N. C., to proceed to Baltimore, Md., and report to medical officer in command for duty and assignment to quarters—May 11, 1901.
R. M. WOODWARD, surgeon, granted 10 days' extension of leave of absence—May 13, 1901.
G. B. YOUNG, passed assistant surgeon, granted leave of absence for 2 months and 22 days from May 30—May 9, 1901.
W. G. STIMPSON, passed assistant surgeon, to proceed to Guthrie, Okla., for special temporary duty—May 14, 1901.
J. A. NYDEGGER, passed assistant surgeon, granted leave of absence for 10 days from May 13—May 14, 1901.
J. B. GREENE, passed assistant surgeon, granted leave of absence for 10 days from May 13—May 14, 1901.
CARROLL FOX, assistant surgeon, to proceed to Sitka and Juneau, Alaska, for special temporary duty—May 10, 1901.
F. J. THORNBURY, assistant surgeon, relieved from duty at Chicago, Ill., and directed to proceed to Dutch Harbor, Alaska, to assume command of the service—May 14, 1901.
FRANCIS DUFFY, acting assistant surgeon, granted leave of absence for 2 days from May 21—May 16, 1901.
C. F. ULRICH, acting assistant surgeon, granted leave of absence for 10 days from May 14—May 15, 1901.
M. R. MASON, hospital steward, relieved from duty at San Francisco, Cal., and directed to proceed to Dutch Harbor, Alaska, and report to medical officer in command for duty—May 16, 1901.

Psycho-Physical Laboratory.—Efforts are being made to pass the following resolution: Resolved, That we are in favor of the establishment of a Psycho-Physical Laboratory in the Department of the Interior at Washington for practical application of physiological psychology to sociological and abnormal or pathological data, especially as found in institutions for the criminal pauper and defective classes and in hospitals and also as may be observed in schools and other institutions.

Health Reports: The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, U. S. Marine Hospital Service, during the week ending May 17, 1901:

SMALLPOX—UNITED STATES AND INSULAR.

Physical Fitness for Philippines.—The Civil Service Commission has received from the Philippine civil service board a communication regarding the question of physical fitness for service in the Philippine Islands, based on a report from Col. Charles R. Greenleaf, assistant surgeon general, United States army. In addition to the age limitations, minimum eighteen and maximum forty years, it reports that the following disabilities constitute disqualifications of Americans who seek civil service appointments in the islands:

Chronic skin disorders—Diseases of the eyes and errors of refraction, not susceptible of correction by glasses; also chronic diseases of the mucous surface of the eyelids. Catarrhal and purulent forms of ear diseases. Organic diseases of the heart or large blood vessels; all forms of tuberculosis or other pulmonary diseases. Chronic diseases of the gastro-intestinal tract, including diarrhea and dysentery. Diseases of any of the organs included in the abdomen. Venereal diseases. Chronic rheumatism; dropsy of joints; chronic diseases of the bones; varicose veins, if excessive. Habitual intemperance as to alcohol or drugs of any kind. Obesity or marked disproportion of height over weight.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

(Continued from page 953.)

Second Day, Morning.—The morning session opened with a study of bubonic plague based upon the outbreak in San Francisco. L. F. Barker, of Chicago, discussed the clinical aspects of the subject. Plague belongs to the group of septicemic infections. The epidemic in San Francisco was not peculiar, but showed the same features as have been seen in nearly all places in the early stages of the outbreak. The epidemic was a sneaking one, with long intervals between the cases. It is not necessary that a severe epidemic follow this local manifestation of the disease. So far, in San Francisco, there has been no outbreak of plague among the rats; in all great epidemics a rat epidemic has preceded the general outbreak. The majority of cases in San Francisco occurred among the Chinese population, only 3 cases having been met with among the Caucasians. The majority of cases occurred between the ages of 31 and 40 years. This is explained by the fact that there are very few Chinese children in San Francisco. The majority of cases were in the male sex. This feature is explained by the small number of Chinese women in San Francisco. The bubonic type of the disease was the one generally met with; although one case of plague septicemia and one of plague pneumonia occurred. The cases usually begin suddenly with a chill, which is followed by intermittent and irregular fever, nausea, vomiting, nervous symptoms, including delirium and coma. The bubo usually develops in 24 hours. The disease progresses steadily to death in from 4 to 6 days. Chronic cases are accompanied by suppuration. The bubo develops rapidly, it is usually large and involves a group of glands together with the surrounding tissue, which presents hemorrhage and edema. The edema is characterized by a sense of elastic resistance on palpation. Pain is usually present in the neighborhood of the bubo; it is sometimes spontaneous and is always elicited by pressure. The buboes are found in the following situations in order of frequency: groin, axilla, neck, popliteal space and bend of elbow. Cervical bubo is often complicated by enlargement of the tonsils and by ulceration of the tonsils. The pathologists distinguish a primary bubo of the first order, which is the one in which the bacteria first multiply; primary bubo of the second order, which is due to direct extension of the primary bubo of the first order; and secondary buboes, which are due to embolic processes. Clinically, the only classification that can be made of buboes is into primary and secondary. The latter class includes buboes of the second order and secondary buboes. In the pneumonic form the bacillus develops primarily in the respiratory tract. This form presents the symptoms of pneumonia but the sputum contains great numbers of the plague bacilli and large amounts of blood. There is a secondary form of pneumonic plague due to the development of pneumonia in a bubonic case. In some cases the plague bacilli multiply in the skin, producing abscesses and, in some cases, true carbuncles. Cases of septicemic plague may be primary or secondary. Cases of pestis minor in which the patients recover without having been ill enough to have been in bed, are found at the beginning and at the end of epidemics. Such cases are often unrecognized and are a distinct danger to the community in which they occur, because the urine and the feces contain the bacilli. The safest plan is to call all cases of glandular swelling cases of plague until they are positively proved not to be such. The diagnosis is to be made positively by bacteriological examination and it is not necessary to have a living case in order to arrive at a definite conclusion that the condition existing is one of plague. The diagnosis can be positively made from the cadaver. The disease has been confounded with severe malaria, typhoid fever, relapsing fever, venereal bubo, anthrax of the skin, septic conditions without bubo, croupous pneumonia and dengue. Bacteriological examination of the following pathological products should be made: bubo juice, blood, spleen juice, sputum, urine and feces. The serum reaction is not to be depended upon for diagnostic purposes because it occurs late in the disease. When plague is present in a community, every case of fever and every cadaver should be considered to be of plague origin until positively proved by bacteriological examination not to be such. Roux's serum is the only hope in the treatment of the condition. F. G. Novy, of Ann Arbor, discussed the bacteriology of plague. The greatest importance is to be attached to the demonstration of the

bacillus pestis in cases of suspected plague. The bacillus can be detected during life, but it is often a difficult matter. Detection of the bacillus in the blood is not always successful. The American Commission recommended that every case of fever in an Asiatic in San Francisco and every dead body of an Asiatic should be considered a case of plague until proved not to be so by bacteriological examination. The bacillus can usually be easily demonstrated in a fresh cadaver, although inoculation experiments are often necessary before a positive conclusion can be reached. The inoculation should be made into rats if possible. Guinea pigs are not good animals for inoculation experiments on account of their resisting power to the bacillus. Involution forms of the bacillus are common. For ordinary purposes of diagnosis the direct microscopic examination of cover slips is usually sufficient. The San Francisco cases were cases of true plague as bacteriological examination showed, and the infection of a laboratory worker with acute pneumonic plague is a further confirmatory fact. Simon Flexner, of Philadelphia, discussed the pathology of plague. The bacilli of plague may pass through the skin without leaving an indication of their entrance and thence they extend through the lymphatics. The appearance of the lymphnodes in plague is pathognomic on account of the hemorrhage, the character of the edema and the foci of necrosis in the gland and the surrounding tissues. In the secondary buboes the hemorrhage and edema are less in amount and the foci of necrosis in the gland are less numerous. There is no lymphangitis except in the immediate neighborhood of the infected glands, so that no connection can be traced between the primary and the secondary buboes. On account of the irregular metastasis of the bacilli the glands on the opposite side become involved as well as the glands on the same side as the primary bubo, but to a less extent. The smaller glands show cellular proliferation, but the increase in size of the larger glands is due to the hemorrhage, the edema and the enormous number of bacteria that are found in the lymph-sinuses. The latter condition results in an obstruction of the flow of lymph within the glands. The necroses in the lymph-nodes are probably due to the presence of the bacteria occluding the bloodvessels. The obstruction of the lymphvessels with bacteria, however, may act by preventing the passage of lymph from the smaller bloodvessels. In the secondary buboes the enlargement is due chiefly to the proliferation of the cells. Plague pneumonia is usually lobular, although the number of affected lobules may be so great that their coalescence produces a condition similar to that of lobar pneumonia. The exudate contains few cells except red bloodcorpuscles; fibrin is absent, but the number of bacilli is so great that they produce the consolidation by filling the alveoli. The changes in the spleen are those of acute splenic tumor. There is in addition acute splenitis which is characterized by the presence of a large number of polymorphonuclear leukocytes which wander all through the trabeculae and reticulum of the spleen. The enlargement of the organ is chiefly due to the amount of blood which it contains. There are a large number of phagocytes containing red bloodcorpuscles. Metastases are occasionally found in the liver and kidneys producing lesions that resemble abscesses in appearance. The bacilli are thrown off from the glands, if these break through the skin; they are thrown off in the sputum in pneumonic cases; they are often passed in the urine, particularly when the kidney lesion is of a hemorrhagic nature; they are found in the feces when there are hemorrhagic lesions in the mucous membrane of the intestine. In animals, the lesions correspond pretty closely with those found in human beings. The author believes that the system of control in San Francisco is so much improved that when the statement comes that plague had disappeared we can believe it. George M. Sternberg, of the U. S. Army, said that if this small epidemic in San Francisco had occurred 30 years ago we might be reading in the daily papers to-day of 500 or more cases in San Francisco and of the extension of the epidemic throughout other parts of the country. The good results in this epidemic are entirely due to the presence of laboratories and of trained bacteriologists. William A. Park, of New York, said that he had met with 2 cases of plague on a Brazilian ship in New York harbor. Bacteriological examination of the pus from the buboes showed the presence of the *bacillus pestis*. Both patients, who had attended a fatal case of plague while at sea, re-

covered. F. H. Shattuck, of Boston, asked how soon the bacilli appeared in the urine in cases of plague. Victor C. Vaughan, of Ann Arbor, described the condition of the laboratory worker at Ann Arbor who contracted plague pneumonia. The initial symptoms in the case were headache, pain in the back like that of renal calculus, temperature 102° and later 104°, and vomiting. The patient and 2 fellow students who were caring for him were isolated, the door of the laboratory in which he had worked was locked, and his bedroom was thoroughly disinfected. The sputum was very carefully sterilized as soon as brought up. George Dock, of Ann Arbor, showed the temperature chart of the patient in question. The patient presented a pleural friction on the affected side and dulness similar to that elicited in the pneumonia of the aged. The patient had the appearance of a very sick man, which was entirely out of proportion to his physical signs. The spleen became enlarged and painful on the fourth day of the disease. After the last injection of Roux's serum, of which 120 ccm. were administered in the first 24 hours, the temperature fell but not as decidedly as it does in cases of croupous pneumonia. The patient's heart was weak and slow and he suffered from marked dyspnea at one period of the attack. He had ~~arterial and joint pains and a rise of temperature~~ after the injection of the serum. Each of those exposed to the disease received 10 ccm. of Roux's serum. In 2 of these cases urticaria, asthma and joint pains followed the injection. L. F. Baker, of Chicago, said that he did not know how early bacilli might appear in the urine in cases of plague. While all cases are probably contagious the pneumonic cases are the most virulent. It is dangerous to make autopsies in plague cases. The whole country is indebted to Kellogg and Kinyoun for their admirable work in San Francisco. He congratulated the Ann Arbor men on their speedy recognition of the case of plague and on their successful treatment of it. Simon Flexner, of Philadelphia, said that bacilli have been found in the urine in plague cases as early as the third day.

Walter Reed and James Carroll, of the U. S. Army, read a paper entitled *experimental yellow fever*. The authors tried to produce yellow fever in human beings (1) by the bites of *Culex fasciata* which had previously bitten a yellow fever patient. (2) By injecting the blood from a yellow fever patient into a nonimmune subject. (3) And by the exposure of individuals to fomites. The authors succeeded in infecting 4 out of 5 patients by injections of human blood. These cases confirm the presence of the parasite in the blood of the general circulation of patients suffering from the disease and confirms the possibility of its transference by the bite of the mosquito. Inoculation of blood from a case of yellow fever into suitable culture media produced no growth, thus depriving the bacillus *icteroides* of its position as the cause of yellow fever. The paper contains an account of 4 additional cases of inoculation of yellow fever by mosquito bites. One of the patients was bitten 57 days after the insects had been fed on a yellow fever patient. This patient contracted severe yellow fever. The parasite is present in the general circulation of the infected individual both before and after the intermission of the fever. All mosquitoes do not acquire the parasite on biting a yellow fever patient because the organism may not be present in the capillary circulation. The average period of incubation of yellow fever in 16 cases was 87.13 hours, or 3 days and a few hours. The period of incubation in one case was 7 days. The cases may be severe, mild or very mild. Mild cases are difficult to diagnose in the absence of complete data, but such cases may serve as a focus of infection through the bites of mosquitoes. All the cases in the series presented albuminuria with one exception. George M. Sternberg, of the U. S. Army, said that this demonstration of the infection of non-immune patients by the bite of the mosquito makes clear many apparently contradictory facts concerning the etiology of the disease. It explains the occurrence of yellow fever in stevedores when a ship appeared to have no yellow fever on board. It explains why sulphur fumigation disinfected these ships. It explains how the infection traveled from a ship anchored in the harbor to the neighboring land without communication with the shore. He considers the demonstration that the infectious agent is in the blood, and that it may be conveyed to a susceptible individual by the bite of a mosquito. William H. Welch, of Baltimore, said that it is fortunate that the authors had no deaths in their work. They were cognizant of the ex-

trime responsibility resting upon them and the young American soldiers who volunteered, without pay, for the work, were heroes.

James Ewing, of New York, read a paper entitled **a case of malarial nephritis with the massing of the parasites in the kidney**. Albuminuria is nearly always present in pernicious estivoautumnal malaria, and in some cases of severe tertian infection. The acute nephritis of malaria is seldom fatal. When a fatal case does occur, however, the lesions found have been, in the majority of cases, degenerations of the epithelium of the convoluted tubules with an exudate of albumin into the tubules and into the glomeruli, with few parasites in the vessels. The case reported by the author shows that the kidney lesion may be due to excessive accumulation of parasites in the renal capillaries. These parasites were demonstrated by staining the tissues by Nocht's method. The cells lining the tubules were degenerated and their detritus filled the lumen of the tubules. Many of the capillaries were ruptured, producing miliary hemorrhages. There was partial or complete suppression of the urine, which contained a large number of red cells, a large amount of albumin, coarse granular, epithelial and blood casts, with infected red cells and pigmented leukocytes adhering to the casts. The diagnosis was made during life.

Walter B. Jones, of New York, read a paper entitled **septic infection through the stomach and the duodenum**. The stomach and the duodenum contain at all times large numbers of micro-organisms that are capable of setting up a septicemia if a solution of continuity of the mucous membrane occurs. The case of a man, aged 56 years, was cited. The patient had lost weight, had had nausea and vomiting and anemia, from which he had apparently recovered. Then he was taken with a chill and intermittent fever that suggested septic thrombosis. At autopsy, an adenoma was found on the mucous membrane surface of the greater curvature. The surface of this tumor was eroded and inflamed. This was thought to be the original seat of the infection. The author advanced the opinion that such a complication might be seen in cases of gastric ulcer and gastric carcinoma, in both of which there is a solution of continuity of the lining of the stomach. Probably septic poisoning through breaks in the lining of the stomach and duodenum are more frequent than is at present believed. S. J. Meltzer, of New York, said that such cases might come under the head of terminal infections. Francis P. Kinnicutt, of New York, said that the cases of fever of septic type in which the patient recovered could hardly be called cases of terminal infection. The observations of cases in his own wards tend to make him agree with the opinion of James. Walter B. Jones, of New York, said, in answer to a question by Cabot, that leukocytosis had been found in some cases. Lowered resistance would undoubtedly render a patient more susceptible to such an infection.

John H. Musser, of Philadelphia, read a paper for himself and Norman B. Gwyn, of Philadelphia, entitled **two cases of streptothrix infection, one of bronchopneumonia, the second abscess of the brain**. The patient, who had an abscess of the brain, was a man, aged 22 years, who was poorly nourished and who had a family history of tuberculosis. He began to have convulsions with no other symptoms except hypesthesia of the right side. The convulsions recurred and coma appeared. Lumbar puncture was negative. At autopsy an abscess was found in the white matter of the brain behind the fissure of Rolando, somewhat involving the cortex. The abscess contained foul smelling pus in which a streptothrix was found in a cover glass preparation. Cultures were negative and animal inoculations were not conclusive. The other case presented a bronchitis with increased frequency of pulse and respiration. The condition went on to the production of a bronchopneumonia. The sputum showed a streptothrix. The patient died, but an autopsy was not permitted. These organisms may, of course, be one of the branching forms of tubercle bacilli. Simon Flexner, of Philadelphia, referred to a case simulating tuberculosis which he reported to the society several years ago. A. C. Abbott, of Philadelphia, said that he had seen a condition in one of the lower animals that resembled tuberculosis. From this animal he had obtained a streptothrix in pure culture, but was not able to inoculate it into animals.

McPhedran, of Toronto, showed a specimen of blue urine

that had been passed in his office by a neurasthenic patient. The coloring matter was pure indigo blue.

Edward L. Trudeau, of Saranac Lake, N. Y., exhibited some specimens of chemical substances obtained from the tubercle bacillus. These consisted of (1) a reddish coloring matter. (2) A wax, which constituted 30% of the tubercle bacillus. This wax is the ingredient that causes the bacillus to resist the action of nitric acid after it has been stained. It is possible that this wax is the cause of the resistance of the bacillus to the disintegrating action of the tuberculous processes. (3) The outside coating of the bacillus is composed of cellulose. (4) Three nucleoproteids, having different coagulating points and from which pure nucleic acid was obtained which had a high percentage of phosphorus. This nucleoprotein is probably the active ingredient of the tuberculin. (5) The tubercle bacillus contains glycogen.

A. C. Abbot, of Philadelphia, reported a product of the bacillus pyocyaneus that presented some of the reactions of cellulose and some of the reactions of mucin. This body was found in old cultures only and seems to be a degenerative product.

Victor C. Vaughan, of Ann Arbor, read a paper entitled **the toxin of the colon bacillus**. He has studied the toxin of the colon bacillus chemically, and is of the opinion that it is an intracellular product. He uses for his studies a large moist chamber for growing the organisms in which he can develop 20 square feet of culture. [J. M. S.]

Third Day, Morning.—Franz Pfaff, of Boston, read a paper entitled **some observations made in a case of diverticulum of the esophagus**. The patient suffered from loss of weight and regurgitation of food. The gastric digestion was shown to be normal and the motility of the organ was satisfactory. A tube was passed into the stomach with no difficulty, but it was possible to remove from the esophagus food that had been swallowed as much as 20 hours before. The patient was fed through a tube for 3 years and then, when he tried to pass the tube, it was arrested about 37cm. from the mouth. On one occasion 90ccm. of undigested food were evacuated from the esophagus, which contained lactic acid, but no pepsin and no hydrochloric acid. After this material was evacuated the tube could be passed on into the stomach with ease, and a fluid containing hydrochloric acid was obtained. The absence of saliva from the stomach, in this case, had no influence on gastric secretion nor on the motility of the organ. During the last year and 6 months the size of the diverticulum has not changed. The patient has to empty the diverticulum before he can introduce the tube into the stomach. Experiments have shown that carbohydrates are digested to considerable extent in the esophagus. Lactic acid is always present in the esophagus, but the amount is decreased by keeping the esophagus clean. There is practically no absorption from the esophagus of even readily diffusible substances like sodium chloride. Feeding by means of the stomach tube has resulted in a gain of 43 pounds in the weight of the patient. In a second case of diverticulum of the esophagus, tube-feeding resulted in a gain of 23 pounds in weight in a short time. In the first patient spoken of in the paper an X-ray photograph showed the diverticulum low down near the cardiac end of the stomach. S. J. Meltzer, of New York, said that the mucous membrane of the esophagus absorbs slowly. In cases of diverticulum the mucous membrane is altered in appearance so that absorption does not take place. In a patient suspected of having a diverticulum of the esophagus, vomiting from the stomach would be an indication that a diverticulum was present. If the condition was one of organic stricture fluids could pass neither from the esophagus into the stomach nor from the stomach into the esophagus. But in the case of a diverticulum, while fluid would not pass from the esophagus into the stomach, vomiting from the stomach would be possible.

(To be Continued.)

Abstract of Papers and Discussions at the Annual Meeting of the American Surgical Association, held in Baltimore on May 7th, 8th and 9th, 1901, the President, Dr. Roswell Park, of Buffalo, in the Chair.

MAY 7, 1901, MORNING SESSION

Immediately after calling the meeting to order, a short executive session was held and then the scientific business was commenced.

The President read his Annual Address, entitled "Some Phases of the Cancer Question," and stated that patholo-

gists, who study the condition purely from the dead-house point of view, have confronted some of the greatest problems which it has to offer, but have also missed some of its most important aspects. The parasites of cancer, be their nature what it may, are in all probability polymorphic in extreme degree and masquerade under many forms, changing with their different stages of reproduction. There is no other disease which is characterized by metastasis in which the pathologists decline to see evidence of parasitism. Every metastasis of cancer has the form and significance of an inoculation experiment only performed under the most favorable, because natural, conditions. The primary question after all, is the general one of parasitism but it has not yet been reduced to a question of just what parasites. In the author's opinion it may and probably will be found that cancer is not a question of any single organism, and possibly not even of a single class. The latest work of Roger Williams was then quoted at some length and reference was made to Demarquay, who collected one hundred and thirty-four cases of cancer of the penis, whereas in only one instance was the wife affected with uterine cancer. Numerous cases are now on record of cancer along the track of the trocar used in tapping for ascites due to cancerous disease, and surgeons now generally admit this traumatic dissemination of the disease by inoculation of wounds during operations. From studies already made in the New York State Laboratory it seems to be clear that death in cases of cancer comes about, as in so many other diseases, by a sort of terminal infection, which is a conspicuous feature of the disease and has not hitherto attracted sufficient attention. The exact nature of these terminal changes has not yet been made out beyond what is implied in the term "Hematogenous." The predictions of the Italians have failed in many respects, and it is by no means so easy to successfully inoculate animals with the yeast as has been generally supposed. By comparing tumors removed by operation with those removed post mortem, it became evident that the organisms either increased rapidly during the period just before death, or that they proliferate in the tissue immediately after death. In practically all scrapings from cancer could be seen either small hyaline refractive forms which in suspension possess a characteristic oscillating motion or larger forms with projecting pseudopodia or sacular forms containing very refractive spherical bodies.

The work of Dr. Gaylord, in association with the author was then referred to at considerable length, and reference was made to a number of publications by these gentlemen on this subject. It was mentioned that considerable difficulty is added to the work of investigation by the extraordinary polymorphism of many of the minute organisms found in cancer. Plimmer's work was referred to to a considerable extent and deductions drawn therefrom. It appears that the protozoa are capable of producing in man lesions of widely different nature from mere infection of epithelium, and Pfeiffer has shown that they might produce both in man and in animals. A full report was promised in a short time of the results of inoculating seventy-two animals with the technique employed.

Pfeiffer's work was quoted from at some length and various deductions were drawn therefrom.

That cancer begins as a purely local infection has been verified by the recent paper by the author in the laboratory at Buffalo, and also that it kills by becoming generalized, which is equally true of tuberculosis, and these constitute apparent exceptions to the above rule, but even they do not prove that the disease did not have a local beginning.

The author concluded his paper by stating, "I want to make it as evident as possible that carcinoma is an epithelial infection."

Dr. Thomas S. Cullen, of Baltimore, gave a lantern slide exhibition of The Early Signs of Carcinoma of the Uterus.

Dr. W. S. Halsted, of Baltimore, made a few remarks on a Brief Consideration of the Cases of Cancer of the Breast treated at the Johns Hopkins Hospital since 1839. He spoke of the difficulties of getting a good picture of the cancer, and stated that drawings are made in every case to file away with the records. He reported having operated on 320 cases of carcinoma of the breast and 450 cases of the breast tumor, as well as three cases of primary sarcoma of the breast. Intra-canalicular myxomata and fibromata are often spoken of as sarcoma, but in Dr. Halsted's opinion they are not. He referred at great length

to the difficulty of compiling statistics and demonstrated the method of grouping the cases at the Johns Hopkins in order to arrive at the proximate results. His experience is that the percentage of recurrences is very variable, and he reported that out of 129 cases operated upon, 51 had been cured.

Dr. W. B. Coley of New York read a paper entitled: "Late Results of the Treatment of Inoperable Sarcoma with the Mixed Toxins of Erysipelas and Bacillus Prodigiosus, with a Report of Cases."

The writer referred to his paper published in August, 1898, (1) in which he gave the results of 140 cases of inoperable sarcoma treated with the mixed toxins of erysipelas and bacillus prodigiosus. In 24 of these the tumor completely or partially disappeared as a result of the treatment. In 84 cases of this series the sarcoma was round-celled; in 21 spindle-celled; in 9 melanotic; 2 chondrosarcoma; in 12 the type of cell was not stated, though the diagnosis was confirmed by the microscope; 6 were inoperative carcinoma, the diagnosis resting upon clinical symptoms, combined in most cases with a history of repeated recurrence.

In 40 cases of the round-celled, or slightly less than half, more or less improvement was shown by decrease in size or cessation of growth. In only 4 of these was the treatment permanently successful.

Of 21 cases of spindle-celled sarcoma 10 disappeared entirely; all the remainder showed marked improvement.

In no case of melanotic growth more than temporary improvement was noted.

At the time of this report 8 cases had remained well from 3 to 6 years; 9 from 1½ to 3 years.

In addition to these personal results, the paper contained a summary of results in 35 cases successfully treated by other surgeons employing the same method. Of these 35 cases 10 were round-celled; 10 spindle-celled; in 5 the diagnosis was clinical only; in 5 there was, in addition to the clinical signs of sarcoma, a history of recurrence after operation; in 4 the diagnosis of sarcoma was confirmed by microscopical examination, but the type not stated; 1 was an endothelio-carcoma.

Of these 35 cases 26 disappeared completely; 2 others decreased so much that only a small node was left, which was easily excised. One of the latter cases was well three years and the other 1 year at the time of the report.

Of the 35 cases referred to, 14 were well over two years, and 6 cases over 3 years.

The object of the present paper, the author said, was to determine, if possible, from a careful tracing of the successful cases, whether the action of the toxins upon sarcoma is to be regarded as of temporary or permanent value; in other words, whether or not it is entitled to be called curative.

While at the time of his report in 1898, 8 of his personal cases had remained well from 3 to 6 years, he stated that this number had now increased to 15 that had remained well from 3 to 8 years. Of these 2 recurred after 3 and 6 years, respectively; the second, after having remained well for 6 years, is now again under treatment. This being an exceedingly interesting case, the writer stated that it would shortly be published in detail. All the cases comprising the foregoing series were hopeless, inoperable cases and the diagnosis was confirmed by the microscope with two exceptions, and in these the history of the cases together with the clinical appearances, made the diagnosis of sarcoma unquestionable. The type of tumor in the fifteen cases that passed the three year limit, was as follows:

Spindle-celled sarcoma	8
Round-celled sarcoma	2
Mixed-celled sarcoma	2
Epithelioma	1
Sarcoma (clinical diagnosis only)	2

It is worthy of special note that two of the successful cases now well 3½ and 4½ years, respectively, are sarcoma of the parotid gland. Butlin, in his last edition of "Operative Treatment of the Parotid Gland" states that "up to the present time there are very few instances of cure by operation of undoubtedly malignant disease of the parotid." In the author's two cases treated by the toxins the diagnosis was not only confirmed by a competent pathologist, but further, by a history of repeated recurrence after operation. Another case still is also worthy of special mention, inasmuch as it shows that the toxins may be taken

for long periods of time without harm. The patient, a well-known physician, with eight times recurrent spindle-celled sarcoma of the soft parts of the chest (anteriorly) was treated with small doses of the mixed toxins with varying intervals of rest, for nearly three years. The patient regained his usual health, and has now been perfectly well over six years from the beginning and four years since the cessation of the treatment. The tumors, while originally pure spindle-celled, were becoming more mixed with round cells and more vascular with each recurrence. In other words, the disease, as so often happens, was increasing in malignancy until the toxins were begun.

(To be Continued.)

NINETEENTH GERMAN CONGRESS FOR INTERNAL MEDICINE.

(Continued from page 954.)

Meyer, of Berlin, took the field to defend his diplostrep-tococcus as a specific organism. He described his experiments and emphasized the connection between the affection of the tonsils and rheumatism. He has found his organisms in 12 cases of angina which led to, or accompanied, articular rheumatism. Injection of the organism produced typical joint affections, and he obtained the coccus from the infected animals. Menzer of Berlin also opposed Singer, and claimed that he and Meyer have for the first time experimentally caused multiple arthritic rheumatism with the subsequent endocarditic affection. Glaser of Berlin also opposed Singer's views. Michaelis of Berlin defended Meyer and declared his belief that the organism found by Meyer is the specific cause of the disease. The discussion assumed a personal character and therewith lost scientific interest.

Glück, of Berlin: "The Development of the Surgery of the Lungs." Glück described his experiments, which prove that one can resect lobes of the lung, or even a whole organ, and reports 14 cases which he has successfully operated on.

Von Schrotter, of Vienna, reported "A Rare Cause of Outside Paralysis of the Recurrent—an addition to the Symptomatology and Diagnosis of open Ductus Arteriosus." In this case—congenital heart lesion—the autopsy showed that the recurrent was injured by being wedged in between the dilated ductus arteriosus and the aorta. Roentgen photographs showed clearly the pathognomic sign of persistence of the ductus, first described by Zinn; a shadow in the second left intercostal space. He considers the case of significance in the question of differential diagnosis.

Kraus and Graz reported a case of Recurrent Paralysis in Stenosis of the Mitral Valve, due to strangulation of the nerve following the topographical changes due to the dilatation of the right ventricle.

Vogt, of Berlin, described the advantages which could be gained if the work on the anatomy of the brain could be done at some central station, instead of being scattered as at present.

Hampaln of Riga: "The Hospital Mortality in Pneumonia" claimed that the means of transporting the sick is to blame for a large proportion of the hospital mortality; he failed, however, to suggest any improvement.

Rosenfeld, of Breslau, on "The Fatty Degeneration of the Organs," claimed that no such thing as fatty degeneration exists, but that fat wanders from other tissues into the organs—as from subcutaneous tissue into the liver in cases of phosphorus poisoning, etc.—in order to take the place of some substance which is lacking. In all cases of poisoning there is a lack of glycogen in the liver, and Rosenfeld thinks the fat destined to take the place of the lost glycogen. He denies in short that there is such a thing as fatty degeneration.

The Congress closed with a discussion following a paper by Moritz, of Munich, on "The Results of the Orthodiagraphic Determination of the Heart Boundaries and their Bearing on Percussion." Moritz concluded that percussion does not exactly determine the heart boundaries—in 68% of 89 cases he found the results of percussion correct when controlled by his Roentgen ray machine.

Third Session.

Rosenstein, of Leiden, in the chair.

The third session opened with a paper by Mendelsohn, of Berlin, on "The Recuperative Power of the Heart as a

Means of Judging the Heart Function." Mendelsohn described first the different methods which have been suggested to conclude from the amount of work necessary in a given case before the patient feels tired, whether the heart performs its normal function or not. It is, however, not always advisable to carry the test so far, and so Mendelsohn has endeavored to fix a new criterion. While a person is performing some work the normal heart changes the rapidity of its stroke, to return sooner or later to the normal rate, according to the amount of work done. If the heart is diseased, if it is not sufficiently nourished during the diastole, the pulse rate will remain high for a much longer time than the rate of the normal heart after performing the same amount of work. From this change in the pulse rate, and from the time required for the rate to become normal, Mendelsohn draws his conclusions as to the functional power of the organ. He advises the study of the heart function in this way, and to regulate the patient's mode of life accordingly.

Baeltz, of Tokio, Japan, thinks one cannot always judge from the pulse rate. He himself has a weak heart—often in mountain climbing a pulse rate of 120—yet he feels no bad effects. He mentioned the wonderful recuperative power of the Japanese couriers, who can day after day, cover 100 to 150 kilometers.

Bier, of Greifswald read, by special request, a paper on "The Place of Artificially Caused Hyperemia in Therapy." Bier has found his method—the causing of venous congestion by placing a rubber bandage around the limb—a method which he originally proposed for the treatment of tuberculous arthritis, of no value in cases of carcinoma, sarcoma or lues; he has been successful, however, in cases of arthritis following gonorrhea. He finds that it shortens the course of erysipelas, and that it aids in bringing a beginning phlegmon to resorption. He emphasized that one must use only the "hot congestion," "cold congestion," when the bandage is drawn too tight, or "white," or "lymph congestion" is directly injurious. The advantages of the method are: If used rightly it quiets pain—otherwise it is contraindicated—and aids in the resorption of pathological growths and exudates. This latter can best be obtained by combining hyperemia with massage. Bier reported a series of experiments made by Noetzel to ascertain whether the hyperemia has any direct effect on bacteria; 51 of 67 animals lived after injection, into the congested limbs, of doses of anthrax which are ordinarily certainly fatal. Bier described further the use of hot air and showed a simple apparatus long used by himself for applying the heated air. In spite of the discussion as to the value of hot air, Bier believes that it exerts an influence upon the deep-lying blood vessels. He recommends the method to the practitioner, especially in the treatment of rheumatism. Müller, of Würzburg, described the changes in the blood following artificial hyperemia. He claims that the red blood corpuscles increase in number.

Hoffman, of Düsseldorf, discussed "Paroxysmal Arrhythmia. Heintz, of Erlangen, has experimented on the effect of external irritation (chemical and thermal) on the deep-lying blood vessels. He concludes that temperature variations of several degrees can be produced by external changes.

Gumprecht, of Weimar; "The Importance of Iodine as a Vasomotor Stimulant." Gumprecht has found no other effect of iodine on the blood vessels than the toxic effect of large doses. Clinically he has found no influence of iodine on the pulse tension. He considers it false therapy to use iodine in cases of hemorrhage from the lung. Asher, of Bern, noticed the necessity of studying the effect of iodine on the heart nerves—not alone on the pulse tension. Lewy, of Berlin, emphasized the value of iodine in irregular pulse rate.

Strassburger, of Bonn, read a paper on "The Fermentation-dyspepsia of Adults."

Courmont, of Lyon, read in French two papers, the first on "The Hyperleukocytosis in clinical and experimental Rabies." He has found that an enormous increase in the number of the polynucleate neutrophile cells—up to 95%—takes place in all cases of rabies. He points out the great value of this symptom in diagnosing the disease, although hyperleukocytosis with increase of the polynucleated cells may occur in other diseases, a disease without this increase can never be rabies. This condition continues several hours after death; the fluid from the lungs of a normal dog contained 50% of polynucleated cells, while that from the rabied animal contains over 80%.

Courmont's second paper was on "Serum Diagnosis in Tuberculosis." Arlonig and Courmont have shown that the tubercle bacilli in serum from tuberculous patients be some agglutinated. Courmont described the difficulties in the way of the method, and emphasized especially the need of carefully examining the cultures, and of ascertaining their toxic equivalent. He then gives the results of a series of experiments carried out at the abattoir at Lyon; a large number of animals were tested with the agglutination test, and the results compared with the results of the examination made by a veterinary surgeon after the animals were slaughtered, the surgeon having no knowledge of the results of the serum test. In all but one case the serum diagnosis proved correct.

Volhard, of Giessen, communicated a valuable paper on "The Fat-splitting Ferment of the Gastric Juice." Volhard has found a ferment which rapidly splits fats when they are in the form of an emulsion.

The session concluded with papers by Reissner, of Bad Nauheim, on "Why is Free Acid Lacking in Cancer of the Stomach?" and one by Müller, of Würzburg, on "The Extent of Starch Digestion in the Human Mouth and Stomach."

The fourth session under the presidency of von Jaksch, of Prague, opened with a demonstration of a case of so-called idiopathic dilatation of the esophagus, by Strauss, of Berlin. Strauss also demonstrated a number of instruments which he has found useful in the diagnosis of the condition. Von Jaksch, of Prague, demonstrated preparations from, and described, a case of multiple periostitis with peculiar changes in the blood. A young girl suffered from a multiple inflammatory affection of the periosteum with fever and a continual increase in the number of the mononucleated neutrophil leukocytes, while the polynucleated cells continually decreased in numbers. Later large nucleated red blood corpuscles and cells showing polychromatic degeneration appeared. Shortly before death the number of the eosinophile cells increased. Patient died with well marked anemic symptoms. The autopsy showed a tumor of the spleen; the bone marrow in some of the bones had more or less disappeared. Although leukemia can be the cause of changes in the bones themselves, von Jaksch is inclined to consider the case peculiar to itself—a case of disease, the chief characteristic of which was the multiple inflammatory affection of the periosteum, the secondary characteristic being the changes in the blood.

Strufler, of Munich, and Hirsch, of Leipzig, presented patients with hernia diaphragmatica.

Franke, of Munich, demonstrated a new instrument for measuring pulse tension.

Von Hausemann, of Berlin, discussed and showed a large number of alcohol preparations of syphilis of the lung. He believes the cases were undoubtedly syphilis, since the patient gave a history of lues, and since he was unable to find tubercle bacilli in the nodules, and finally since the infection of animals with the material gave negative results.

Levy-Dorn, of Berlin, demonstrated an apparatus constructed on the same principle as the apparatus demonstrated by Moritz, of Munich, at last year's congress, for more exact work with the Roentgen rays. The principle is to cut off all rays from the tube except those which fall vertically upon the object to be examined, thus avoiding the magnification following the use of the whole cone of rays. Moritz defends his machine, (which by the way is of course patented), and claims that it does absolutely exact work.

Michaelis, of Berlin, described a case of Giant Cell Degeneration of the Blood-generating Organs, with Peculiar Changes in the Blood. A woman of 50 years had an attack of influenza 10 weeks previous to hospital treatment. When first seen she was very cachectic, and had an enormous tumor of the spleen, lymph glands were not swollen. The white blood corpuscles rapidly increased (1.220) with a large number of lymphocytes (75%) and 7% neutrophile myelocytes. The autopsy showed enormous tumor of the spleen, lymph glands not swollen. Bone marrow red, but not very soft, no changes in the bones. The microscope showed a great increase of the giant cells of the bone marrow, and giant cells in the lymph glands, liver and spleen; and in spleen and liver some small celled infiltration. Michaelis considers his case analogous to leukemia.

Jäger, of Königsberg i. P., gave a statistical paper on "The Spread of Epidemic Cerebrospinal Meningitis." Aside

from the great value of the bacteriological examination now often carried out, with the aid of lumbar puncture. Jäger considers a study of statistics of great value. He demonstrated a large number of maps, tables, etc., and comes to the interesting conclusion that the disease in Europe is imported from Africa, from the Eastern States especially New York and Massachusetts. Jäger concludes from his study that an endemic disease focus must exist in these states, notably in New York. According to his maps the disease in New York and Massachusetts is sharply defined by the very unnatural physical boundaries of said States—a fact which might lead to the probable conclusion that said States kept better statistics than their neighbors. Jäger also states that the disease is a disease of filth and unhygienic conditions. The cause of the disease is undoubtedly the Jäger-Weichselbaum diplostreptococcus.

Fifth Session.

Dehio, of Dorpat, in the chair.

Munzer, of Prague, discussed "Febris hepatica intermittens with remarks on the formation of urea." He decides that Febris hepatica intermittens is an independent disease, and from his study of one case that the liver is not to be considered the special organ for the formation of urea.

Rosenstein, of Leiden, points out that experiments on pathological livers are no proof of the normal function of said organ. Intermittent fever occurs in a number of different affections of the liver, so in hypertrophic cirrhosis. He does not believe that Fabris intermittens hepatica exists as an independent disease.

Hirsberg, of Frankfurt a. M., "The Operative Treatment of Hypertrophic Cirrhosis of the Liver." Hirsberg described at length a case in which he could arrive at no other diagnosis than hypertrophic cirrhosis: he decided to operate and drain the bile ducts; he performed laparotomy, found the larger bile ducts free, so opened the smaller bile ducts through the liver substance. A fistula was formed which discharged quantities of bile at first, later less and less, until it closed on the thirtieth day. Patient recovered and has remained well since operation, about one year. Maunyen, of Strassburg, considered the prognosis in cases of atrophic or hypertrophic cirrhosis by no means pessimistic; both affections may heal spontaneously. He expressed his doubts that Hirsberg's case was really an hypertrophic cirrhosis, especially because the liver tissues had not become hardened. He thinks it was an infectious cholangitis. Rosenstein, of Leiden, questions the diagnosis because there were no gastric symptoms at first, etc. He considers Hirsberg's case of no value as proving the advisability of operation in genuine hypertrophic cirrhosis: operation might be of value in cases where the distention of the bile ducts threatened to cause cirrhosis. Hirsberg answered Ewald, of Berlin, and states that the bacteria coli communis was found in the bile; he holds to his diagnosis until some one suggests a more probable one.

The second main topic of the congress, "Acute Myelitis," was treated from the clinical standpoint by von Seyden, of Berlin. Von Seyden first gave a brief history of the development of our knowledge of the disease; the same dates from the middle of the last century. The complex of symptoms was known long before the anatomical lesion was recognised. Myelomacia was the name first applied to all transverse lesions. Gradually the inflammatory process was separated from the whole sum of the diseases of the cord and placed aside as an independent disease. We now distinguish the following different forms of the acute process; (1) inflammatory softening, a severe form and also a result of inflammation not to be separated from the inflammatory process as was formerly done. (2) Hemorrhage (Hematomyelia) likewise not markedly differentiated from the inflammations, neither clinically nor anatomically. Myelitis occurs in four forms; (1st) transverse myelitis; (2) disseminated myelitis; (3) poliomyelitis. Degeneration following cachexia, anemia, diabetes, etc., is to be excluded. (4) Compression myelitis, especially that due to caries of the vertebra, which is clinically related to the acute myelitis, although there are certain differences. The inflammatory changes accompanying tumors of the cord are so clearly marked, yet these have resemblance to the acute forms. Degeneration of the cord is the chief part in the etiology of myelitis. These cases were to be sure, only certain in poliomyelitis; to be considered as casual factors are the diplostreptococcus of Jäger-Weich-

selbaum and the streptococci. Myelitis occurs principally after infectious diseases; influenza, typhoid, even simpler diseases, as angina, also in pregnancy and during confinement. Part of these cases following infectious diseases have been cured. Trauma must further be considered as an etiological factor, not only local trauma but also general shock. Alcohol, lead, arsenic, carbonic oxide can also act as etiological factors. Fright has been the cause in one case. The causes of chronic myelitis are tuberculosis, syphilitic and gonorrhea. The symptoms depend upon the location of the disease in the different segments of the cord-bulbar, cervical or dorsal segments. The initial symptoms are of importance. The disease appears sometimes so rapidly that we have the clinical picture of a myelitis acutissima or apoplectica, though even here there are often slight prodromal symptoms. Again the disease appears more gradually reaching its height after several days. We are unfortunately often unable to prevent the progress of the disease: it goes on either (1) ascending, with the dangerous result of acute bulbar paralysis, which is not always fatal, or (2), the disease progresses transverse directions; or (3), neuromyolytic symptoms appear—cystitis, decubitus and trophic disturbances which may lead to gangrene. Sometimes these complications recede, and then the prognosis becomes better as regards life, but not as regards complete recovery. Both the transverse and the disseminated myelitis are to-day considered curable, since exudates and hemorrhages can be resorbed. The treatment can only be symptomatic; von Seyden lays the greatest stress upon careful nursing. The pathological anatomical side of the question was treated by Redlich, of Vienna, who distinguishes with Leyden and Goldscheider transverse, disseminated, diffuse, and polymyelitis. These forms fuse into one another, polymyelitis into the disseminated form, and this into the transverse and the diffuse forms. Larger disease foci show always a change in the consistency of the cord, even to genuine softening, which is due in part to edema and hyperemia, in part to true necrosis of the tissues. Acute polymyelitis shows in its fresh stages all the characteristics of an inflammatory process, with the principal pathological changes in the blood vessels. These changes follow mostly, though not exclusively, the arteria spinalis anterior and the arteria centralis. It is, however, entirely possible that a poliomyelitis may be limited to the acute degenerations of the ganglion cells. Redlich believes it impossible to give an exact anatomical definition of acute myelitis, from the fact, if from no other, that we have no valid definition of inflammation in general. The question whether bacteria are the direct cause of acute myelitis is of great importance; bacteria have been found in a small number of cases, but in the majority of cases the disease is probably not due to the direct action of the bacteria, but to the prognosis and the therapy, it is to be kept in mind that the symptoms are not always due to a destruction of tissue, but to the pressure of edema, hemorrhage, etc.

Von Strümpell, of Erlangen, followed with a paper on the same subject. He would call only those affections myelitis which are caused by an external factor acting locally on the tissue, and where the primary change in the tissues is followed by the reactive, reparative, processes in the tissue, especially the processes in the blood vessels. It is especially difficult to find the cause of myelitis because we can neither observe the diseased focus itself, nor examine the pathological products of the same. The examination of the cerebrospinal fluid obtained by lumbar puncture can be of help. v. Strümpell has found lumbar puncture of value in the two cases in which he had occasion to try it. In the first case myelitis followed a panaris. Lumbar puncture gave a liquid turbid with leukocytes, which contained staphylococci in large quantities. The second case was one of disseminated myelitis, which began with a neuritis optica. The cerebrospinal liquid was perfectly clear and sterile. The first case was therefore bacteriogenic inflammation, the second hematogenotoxic. These latter cases are often recognizable from the elective character of the affection. v. Strümpell observed such a case following erysipelas, limited almost entirely to the posterior columns. The more chronic the action of the toxin, so much more the picture of the inflammation recedes, and we find degeneration of the nervous tissue with consequent hyperplasia of the connective tissue. In this sense one can speak of chronic myelitis, provided the disease is of exorganic origin. The hereditary endogenic affections

of the cord cannot be counted with the forms of myelitis; as also multiple sclerosis which v. Strümpell considers an endogenic affection. Schültze, of Bonn, emphasized the affection of the meninges which often accompanies myelitis, especially poliomyelitis. He considers lumbar puncture of great value in diagnosis. Von Kahlden, of Freiburg, emphasized his standpoint in pathology—that the primary changes in inflammation are not in the blood vessels, but in the parenchyma. Rothmann, of Berlin, recommended the method of Lanie for the study of the pathogenesis of myelitis—injection of bacteria, etc., into the cord from the lumbar artery. Goldscheider, of Berlin, upheld, in opposition to v. Kahlden, the old theory that the process first begins in the blood vessels. This explains easily the fact that the ganglion cells are affected in groups. Richter, of Berlin, reported 6 cases of myelitis in children, following scarlatina, diphtheria and lues.

Sixth Session.

Ewald, of Berlin, presiding. The first paper of the afternoon was read by Wiener, of Prague, on "The Synthetic Formation of Uric Acid in the Animal Body." Wiener fed hens with different substances which contained no nitrogen, at the same time injecting urea, and found an increase in the excretion of uric acid after feeding glycerine and those oxy-acids, ketone acids and dibasic acids which contain a chain of three carbon atoms. He found the largest increase in the excretion of uric acid after feeding the dibasic acids, which leads him to the supposition that all the other active substances are first changed to dibasic acids. He obtained similar, although quantitatively smaller, results in the human body. All of the compounds which he examined produced no increase of uric acid when added to the isolated liver of vertebrates except the tartaric acid and its ureid, the dialuric acid. From his experiments Wiener concludes, (1) That not only in birds, but also to a less extent in animals, a synthetic formation of uric acid occurs; (2) That the process consists in a changing of the active substances to dibasic acids with a chain of 3 carbon atoms, which acids then change to tartaric acid; a part of the radical of urea joins this latter acid, forming the ureid, and this passes by the addition of a second part of the urea radical into uric acid. In the human body this synthesis plays a small role, but it is possible it attains a higher significance in pathological conditions, especially in gout.

Mayer, of Karlsbad, "Experimental Researches on the Katabolism of Sugar in the Body," a paper which had already been read before the Medical Society of Berlin. Rosin, of Berlin, reported his researches on the quantitative relations of the carbohydrates in the urine and blood, especially of diabetics, which had also been treated before the Medical Society.

Wohlgemuth and Nerberg, of Berlin, "The Physiological Action of the Three Arabinoses." The authors have endeavored to find whether substances which differ only in the arrangement of their atoms, have a different influence on the mechanism of biological processes, and come to the conclusion that such is the case.

Bial, of Kissingen, "Observations and Experiments on Chronic Pentosuria." Authors are not yet agreed as to the pathological significance of the disease; some consider it a disturbance of the metabolic processes, others consider it dependent upon the nourishment. Bial considers that Blumenthal's experiments have excluded the latter supposition. Bial, working with Blumenthal, has found that grape sugar is completely oxidized in the bodies of patients suffering from pentosuria, likewise levulose and galactose. The injection of phloridzin causes a normal glycosuria. The normal amount of grape sugar in the blood proves also that the glycogen of the liver is changed to dextrose as usual. Therefore, there is no relation between pentosuria and diabetes; pentosuria is an affectio in generis. As regards the origin of pentose, it is produced neither from the albumen nor from the carbohydrates, since 500 gr. of thymus, rich in nuclein, did not increase the pentosuria. It must be produced in the body itself, and since it is to be found in the blood, it must be produced beyond the kidneys. Even for the pentoses themselves the patient possesses a normal oxidizing power.

Ellinger and Seelig, of Königsberg i. P., "The Influence of Lesions of the Kidney on the Course of Pancreas Diabetes in the Dog." If one cause an acute nephritis in a pancreas-diabetic dog by injecting cantharidin, one finds that the amount of sugar in the urine becomes less. Not only

the procental and the absolute amount of sugar becomes less, but the relation between the excreted sugar and nitrogen becomes much smaller. This influence of cantharidin on the excretion of sugar disappears much more quickly than the albumen disappears. If an acute nephritis develops spontaneously in a dog suffering from pancreas-diabetes, the same thing occurs; the sugar can completely disappear from the urine. This disappearance of sugar by a faulty excretion of sugar from the kidneys; the amount of sugar in the blood is found in such cases to be considerably increased. The main factor in the diabetic disturbance of the metabolism of the body, the hyperglycemia, persists, while the glycosuria ceases. Maunyn, of Strassburg, doubts the advisability of drawing conclusions from experimental studies, in regard to the human pathology. He has seen in cachectic conditions, for example following pulmonary tuberculosis, that the glycosuria disappeared, while no trace of a kidney lesion could be found.

Sommer, of Giessen, "The Analysis of the Motor Disturbances in those suffering from Nervous Disease, and in the Insane." He has constructed a series of very ingenious instruments for graphically recording and analyzing the motions characteristic of mental disease. The motion is analysed into its three dimensions. The value of the apparatus can best be seen by a study of the curves of knee jerks from patients suffering from tabes, and from hysterical patients. Sommer demonstrated curves, showing that the curves of hysteria show fixed characteristics which cannot appear when the motion is a pure reflex, as in tabes. The Congress listened to Sommer's description of the complicated instrument with marked interest, and it seems indeed that the apparatus will be of great aid in the diagnosis of obscure nervous diseases.

Seventh Session.

Kraus, of Graz, in the chair.

Rothmann, of Berlin: "Experimental Lesions of the Medulla Oblongata." Rothmann has found that a lesion of the pyriad in the dog or ape produces merely transitory symptoms, etc., whereas a double-sided lesion in the dog produced spastic, from which the animal did not recover. The symptoms produced by a lesion in one pyramid had disappeared after a few weeks.

v. Kahlden, of Prague, on "Parencephalia," considered trauma an etiological factor in this disease. He does not believe that the usual explanation for acquired parencephalia—thrombosis or embolism—is sufficient to explain all cases; nor have we sufficient reason to consider lues congenita a casual factor. v. Kahlden then described a case where he thinks trauma was the etiological factor; a child fell from a table and died 14 days later. The autopsy showed no lesion of the skull, but a double-sided parencephalic defect, which communicated on the left side with the ventricle. Benda, of Berlin, considers that trauma will also fail to explain all cases.

The following papers gave rise to an active discussion between the Vienna and Berlin schools, as to whether acute inflammatory rheumatism is caused by staphylococci and streptococci in general or by a specific organism. Singer, of Vienna, representing the one school, reported five cases of acute arthritic rheumatism and two cases of chorea rheumatica. In all cases of polyarthritis and in one of the cases of chorea he obtained from the joint fluids as well as from the different organs, pure cultures of the streptococcus pyogenes, which could also be found microscopically in the tissues. In the second case of chorea with purulent inflammation of the joints, following an angina follicularis, he found pure cultures of the staphylococcus pyogenes aureus. Singer then criticised the publications from the Berlin school, of Westphal, Wasserman, Malkoff and Meyer, who claim to have found organisms with specific characteristics. Singer claims that it is impossible from the standpoint of bacteriology to conclude that a microorganism which shows but small variations of growth, etc., variations which are common to the whole class of the streptococci—is a specific organism. Nor can the experiment be considered positive proof, since it is a well-known fact that inflammations of the joints can be caused by the most different streptococci.

Tuberculosis in St. Petersburg.—Dr. A. N. Rubel recently stated at a meeting of the Society of Hospital Physicians that 37,000 persons or 25% die yearly of tuberculosis in St. Petersburg.

THIRTIETH CONGRESS OF THE GERMAN SURGICAL SOCIETY.

Sixth Session, Friday Afternoon.

(Continued from Page 911.)

The session opened with a paper by Werckmeister, of Zittau on "The Extirpation of the Larynx." Werckmeister has collected 297 cases, 36 of which were fatal. Gluck records 26 total extirpations with a successful result in 23 cases. Werckmeister presented a patient successfully operated on two years ago. von Hacker, of Innsbruck, reported a case of mediastinal phlegmon following an esophatomy, successfully operated on by opening the 9 cm. long abscess early from the neck. Gottstein, of Breslau, described his experience with the esophagoscope in 100 cases, and warmly recommends the excision with the aid of this instrument of small pieces of a tumor as an aid in diagnosis. Kuster, of Marburg, demonstrated a case of osteoplastic resection of the foot and described his method, for which he claimed the advantage of but $\frac{3}{4}$ -1 cm. shortening as compared with Le Fort's method with 3 cm. shortening.

Schuchardt, of Stettin: "Operative Reposition of the Fractured Epiphysis of the lower end of the Femur." Schuchardt fastened the epiphysis with a pin and demonstrated Roentgen photographs and his patient.

Henle, of Breslau: "Pneumonia and Laparotomy," claimed that pneumonia is especially frequent after laparotomy, and that the lowering of the patient's temperature during the operation is the cause. He gives the results at the clinic at Breslau as a proof of his claim, showing that although the number of laparotomies has increased since 1899, pneumonia has decreased, due, he believes, to the methods introduced at Breslau during that year—operating on heated tables and treating the exposed bowel with hot douches. His experiments with animals have shown that animals which were cooled off during the operation recovered much more slowly from the narcosis than the animals which were kept warm, and further that the former always had an affection of the lungs. Henle reported the case of one patient who developed pneumonia on the day following an operation, in which a large cavity was washed out with a cold solution. He grants that aspiration and infection can of course also be the cause of pneumonia, but believes that the lowered temperature of the patient is the cause in the majority of cases. In the discussion following the paper, Czerny, of Heidelberg, asked whether the injection of Schleich's solution in Henle's case could possibly have been the cause of the pneumonia. Henle replied that he thought it might be possible, although only a small quantity of the solution was used. Kronlein, of Zürich, laid the blame upon the narcosis, especially on ether, and the quality of the ether. In his clinic no special precautions are taken against cooling off of the patients, and yet he has lost but one case from pneumonia, a man of 77 years. Kummell, of Hamburg, reported that he has had 40 cases of pneumonia in 1070 laparotomies, of which 40 cases he has lost 11; of these 11 cases 4 were ether pneumonias. The patients who developed pneumonia were very sick individuals, for the most part sufferers from cancer, and with marked cachexia. He consequently has all his patients who have a tendency to bronchitis get up very soon after the operation, or at least change their position. Stolner, of Breslau, mentioned fat embolism in the lungs, which can follow extended operations as well as fractures, as a cause of postoperative pneumonia.

Stamter, of Königsberg: "The use of v. Mikulicz Peritoneal Tamponade recommended the method as a support for the sutures and as a means of checking hemorrhage, especially in operations on the stomach and gall ducts. Kelling, of Dresden, described at considerable length his experiments on the cadaver to determine the mechanism of acute dilatation of the stomach. He finds that in many individuals a passive valvular closure of the cardia and the duodenum exists. In consequence of these valves the stomach can be dilated to its maximum and lose the power of spontaneously emptying itself. Narcosis acts in the latter way by lessening the motile power of the stomach: operations for gall stones by causing local peritonitis of the upper duodenum, and finally tight bandages can hinder the motility of the stomach. Gastropnoxis is an accessory factor. Acute dilatation can be caused in cases of hindrances in the lower duodenum or in the upper jejunum by this valvular closure of the cardia. Kelling criticises the general use of gastroenterostomy in cases of

acute dilatation. One must find and remove the hindrance.

Schmidt, of Cuxhaven, on "Hyperemesis Lactantium and its Relation to Congenital Hypertrophic Stenosis of the Pylorus, Respectively Pylorospasmus, and its Treatment by stretching the Pylorus." Schmidt treated and healed three cases by introducing forceps and forcibly widening the stenosis.

Lobker, of Bochum, Steintal, of Stuttgart, and Borchard, of Posen, discussed Schmidt's paper.

Seventh Session.

The 7th session opened with a paper by von Eiselsberg, of Vienna, on "The Technic of Uranoplasty." He discussed the different methods and their results. The operation often fails because a large fissure remains and a complicated method must be resorted to to close the same. Von Eiselsberg has finally resorted to a method with the aid of the forearm. He cuts a pediculated skin flap from the arm, as in the Italian method of rhinoplasty, using the Italian method of bandaging.

Wolff, of Berlin, thinks that the method proposed by v. Eiselsberg would be of value in cases of extremely large defects, but that one can do without it, as his series of over 200 cases shows. One must operate at two sittings, first forming the flaps and letting them hang in order to favor circulation, and then after a few days sewing them together. He believes that we can do away with Billroth's method. Von Eiselsberg believes that in spite of the operation at two sittings a large number will be unsuccessful. Czerny, of Heidelberg, operates extensively at one sitting, with the patient's head hanging below the horizontal; sutures with wire or silkworm. He has often used Billroth's method. Fistulae remain in about $\frac{1}{4}$ of the cases.

Wolff, of Berlin: "Arthrolysis and the Resection of the Elbow joint." Wolff demonstrated a patient. Von Eiselsberg, of Vienna, reported a case of ankylosis of the elbow following scarlet fever. He operated on one arm with success, using two lateral incisions. The operation on the other arm failed, due to an overproduction of bone. caused, he thinks, by the fact that he did not exactly strike the joint line. Cramer, of Wiesbaden, reported a case where he succeeded in freeing an adherent patella by using Halfarich's method.

Wolff, of Berlin: "The Treatment of Fractures of the Patella," presented a patient whom he had cured by fastening a miniature Malgaigne's screw into the fragments and drawing them together, after having removed the tuberosities of the tibia; he added an osteoplastic operation on the patella. Röntgen photographs taken later showed that the fragments had separated after all, and were only held by the bridge of bone formed by the osteoplastic operation. The fragments showed a separation of some 2 cm. and the patient had considerable difficulty in ascending the stairs. The congress indulged in unbounded merriment when one of the members who had sustained a fracture of the patella some 15 years ago, which had united with a separation of some 6 cm., showed how he could run up and down the stairs with ease.

Bunge, of Königsberg: "Further Additions to the Question of the Carrying Power of Amputation Stumps of the Diaphysis." Bunge would leave the question open whether the bone marrow itself is sensitive or not, but thinks beyond doubt that the callus formed from the marrow for 2 to 3 cm. high in amputation of the fibula, and careful removal of the periosteum.

Bier, of Greifswald, expressed his opinion that careful removal of the periosteum is necessary, yet he would not give up the osteoplastic method which gives the stump natural boundaries. Czerny, of Heidelberg, expressed his surprise that the author of the osteoplastic method now favors operation with the removal of the periosteum. Bier answered that he would still operate all aseptic cases according to the osteoplastic method, but that the method is not suited to infected cases.

(To be Continued.)

Medical Society at Mexico.—At a meeting of the Mexico and Audrian Medical Society in Mexico, May 7th, the following delegates were elected: To the American Association in June at St. Paul, Drs. J. Rule Fritts and G. P. Tolson, of Mexico. To the State Association at Jefferson City in May, Drs. J. Rule Fritts, E. Bridgeford and Eugene Hultz, all of Mexico.

GREAT BRITAIN.

Appointed Health Officer for the Transvaal.—Dr. George Turner has been appointed by Sir Alfred Milner Medical Officer of Health for the Transvaal. Dr. Turner, who prior to the outbreak of the war filled a similar position in Cape Colony, has been provisionally acting as Medical Officer for the Transvaal, and his services have been recognized by Lord Roberts.

Dr. Christian Fenger, of Chicago, has received the Cross of the Dannebrog from King Christian IX, of Denmark, in recognition of his contribution to surgical knowledge.

A Grave Epidemic of scarlet fever, prevailing in Shore-ditch and Bethnal Green, has been ascribed to infected milk.

CONTINENTAL EUROPE.

Dr. Pozzi, in a recent lecture in Paris, paid a glowing tribute to American surgeons, whom he characterized as "scientifically audacious and brilliantly cool."

A Society for the Investigation of Malignant Tumors.—A new society is being organized in Moscow for the purpose of investigating the question of cancer and other malignant growths.

The Governor of California Noted in Russia.—The *Vratch* is making merry over the actions and decisions of the wise governor of California. The assertion is made that he is possessed of a purely Russian spirit. Well may this official be proud of his fame.

A New Sanitarium for Tuberculous Patients.—The city council of St. Petersburg decided to open a sanitarium exclusively for the poor of the city.

A commission has been appointed by the Portuguese government to study the sleeping sickness in the Province of Angola. The commission, which will at the same time include amongst its scientific researches an inquiry into the etiology and the transmission of malaria, will be composed of the following members: Drs. Annibal Bettencourt, Ayres Jose Correa Pinto, Jose Gomes Rezende, Jr., Joao Braz Gouveia, and Annibal Celestino Correa Mendes.

Dr. J. G. Adami, Professor of Pathology at the McGill University, Montreal, has been appointed vice-president of the section of pathology and bacteriology of the International Congress on Tuberculosis, to be held in London in July, under the patronage of King Edward.

"Stomatite Erucique."—The *Medical Age* states that at a recent meeting of the Parisian Society of Biology, M. Artault gave an account of a curious form of stomatitis which he proposes to call "stomatite erucique," the origin of which had been hitherto unknown. It is, however, now known to be caused by eating fruits which have been in contact with the nest of certain caterpillars possessing an urticating property. The inflammation attacks the mucous membrane of the mouth, the lips, the gums, the cheeks, and the palate. The cause is the irritating hairs and secretions which the caterpillars leave in their nests. The disease, as a rule, attacks children who eat fruits which are taken into the mouth whole, such as cherries and gooseberries, and it is hardly ever seen except during the months of May and June, especially in dry years. A mouth-wash composed of tincture of "myrrh" generally cures the complaint very easily.

Anesthetic for an Elephant.—An elephant in the zoological gardens at Hanover, Germany, was recently found to be suffering from a growth upon the lower part of one of its hind feet, and it was decided to remove it. In order to make the animal insensible a dose of six hundred grains of morphia in six bottles of rum was administered. About an hour after the elephant had consumed this combination narcosis was complete, and the operation was performed without any trouble.—*Interstate Medical Journal*.

Foreign Body in the Maxillary Sinus Discovered by Radioscopic Examination.—Dr. Mignon, of Nice, reported in the *Internat. Archiv. de Laryngol.* an interesting case in which the patient, a young man twenty-one years of age, with suicidal intent discharged a revolver against his temple. A few days after the incident, as no symptoms of reaction occurred, an examination by the radioscope was attempted, and it was found that the bullet was lying loose within the left maxillary sinus.

1.—In an attempt to understand the conditions accompanying functional nerve diseases the physician should always remember the immense influence exerted by the mind on the body. It is also important to recognize the influence of suggestion either from without or from within. The moral and emotional side of human nature and the strong desire for sympathy that exists in some individuals, particularly in young women, also has a bearing upon the causation of these diseases. The influence of heredity is a further important factor. Clinically, there are 4 types of functional nerve disease; (1) feigned disease, (2) hysteria, (3) neurasthenia, and (4) functional disease concomitant with or dependent upon organic disease. There may be a variety of motives to induce patients to feign or simulate disease, and in the investigation of any supposed case of this nature the motive should be sought for. In examining a patient supposed to be feigning disease the fact that pressure upon or manipulation of a tender or painful area leads to slight increase in the pulse-rate, to slight variation in the pulse-curve, to dilation of the pupils, and variation in the vasomotor reaction these may serve as diagnostic factors. If hemianesthesia be feigned, there will be no difference in the skin reflexes or in the reaction of the pulse, pupils or respiratory movements on the two sides. If epilepsy be feigned an important sign that would indicate the absence of true epilepsy is the condition of the toxicity of the urine. It is well known that the urine of epileptics is hypotoxic. Hysterical nerve disease should be regarded as partly mental and partly physical, the underlying psychical state being allied to the hypnotic state. Important assistance in the diagnosis of hysteria may be obtained from a study of the plantar reflex; in conditions of health and in purely functional nerve disease the flexor response is the rule; whereas, in cases of organic disease involving the pyramidal tracts, an extensor response is almost invariable. The symptoms of neurasthenia are more subjective than objective, though none the less real to the patient, and, in certain cases, neurasthenia approaches very closely to insanity.

Neurasthenics frequently complain of headache. One of the most frequent forms for this symptom to assume is the "helmet headache" of Charcot. The head feels as if a helmet were pressed down upon it, producing a feeling of tightness all around it. Prolonged mental or physical exertion probably by entailing formation of an excessive amount of waste nerve products with deficient excretion of the same and their injurious effects upon the nerve cells and fibers frequently determines, according to Rennie, the onset of neurasthenia. [J. M. S.]

3.—Ogilvie is of the opinion that a more thorough study of the tropical diseases in the colonies has somewhat shaken the unconditional belief in many statements regarding the inheritance of acquired immunity. The immunity enjoyed by colored races seems by no means so absolute as has been generally taught. In not a few cases, on close inquiry, the immunity of the adult natives

to a certain disease seems to have been the result of an attack of that disease early in life. Furthermore, no gradual immunization has ever been observed in the white races with regard to any of the infectious diseases from which they suffer. Until we have at least some clinical or experimental proof that infectious diseases lead by themselves to a gradually increasing immunity in the offspring the accumulation theory as an explanation of racial immunity will remain an unsubstantial hypothesis. [J. M. S.]

4.—During the year 1900 a record was kept of the incidence of typhoid fever among the inoculated British troops in Egypt and Cyprus. During this period there were, on an average, 2669 uninoculated troops and 720 inoculated troops. Among the uninoculated troops there were 2.5% of cases of typhoid fever. Among the inoculated troops 0.14. The death rate among the uninoculated cases was 0.4%, among the inoculated 0.14%. [J. M. S.]

5.—Edgecombe reports the case of a single woman, aged 38 years, who was highly neurotic and who had suffered almost continuously from anemia for 12 years. During the whole of this time she suffered from trouble in the nasal cavity attended by repeated discharge of blood and pus in small quantities. Examination of the blood showed 23% of hemoglobin, 475,000 red bloodcorpuscles, 1,400 white corpuscles, color index of 2.40 and the presence of nucleated red cells, both normoblasts and megoloblasts. Under treatment with Hommel's hematogen and inhalations of oxygen a great improvement resulted. Later, a recurrence of the blood condition was noted and death finally resulted. The author believes that this case is one of chronic secondary anemia which passed into the pernicious form. [J. M. S.]

6.—Thin reports the case of a boy, aged 11 years, a native of the West Indies, who was suffering from a fully developed and severe nerve leprosy. Three months after the institution of treatment with chaulmoogra oil considerable improvement had occurred and the patient was taking 21 drops daily without discomfort. Five months later there was apparently a slight setback.

Thirteen years later the patient reported that he had been in perfect health for a number of years and that he had been cured by chaulmoogra oil, which he had taken for nearly 3 years. The only evidence of his having had leprosy was found in the mutilation of the hands and feet and in the incomplete restoration of sensation on some parts of the limbs. The author also reports the second case in which nerve leprosy was detected at a very early stage in a youth that had been some years abroad. Complete recovery followed treatment with the local application of pyrogallol acid ointment and the internal use of gurgun oil and arsenic. [J. M. S.]

7.—Harris reports the case of a married woman, aged 46 years, who was the subject of exophthalmic goiter. The patient was operated on for the removal of a tumor in the left breast. In operations upon patients suffering from exophthalmic goiter the condition of the heart is from the first the great difficulty. The heart, which beats irregularly and at great speed probably has thin and dilated ventricles. The anesthetic at once produces acute embarrassment, while the unavoidable loss of blood causes temporary quickening of the already too quick pulsations producing general weakness and exhaustion, which, owing to the anesthetic sickness, cannot at first be remedied by food. Thus, before compensation can be restored the patient sinks, as did the patient whose case is reported. Therefore, in advanced cases of exophthalmic goiter, the author believes that every effort should be made to avert a serious operation. If, however, such an operation is absolutely imperative a course of treatment with remedies of the digitalis class should precede. If the heart does not respond to this treatment the operation should be reconsidered, for undoubtedly the risk in such cases is of the gravest possible character. [J. M. S.]

8.—Robin reports the case of a boy, aged 10 years, in whom a diagnosis of Landry's paralysis of the descending type was made on account of (1) progressive, symmetrical, motor paralysis, which effected the muscles of the neck and then extended to the arms, forearms, chest and legs; (2) non-disturbance of sensation until a few hours before death; (3) absence of rigidity, pain, twitching or spasm; and (4) the unimpairment of the mental functions and the persistence of control over the bowels and bladder. Although the patient had a fall of 10 or 11 feet into a pit, the traumatism seemed not to have any relation to the dis-

ease which caused death, as there was no sign whatever of damage to the vertebral column. The author does not consider the case to be one of infantile paralysis. The case was an extremely rapid one and ended fatally. [J. M. S.]

9.—Higgins reports the case of a married woman, aged 45 years, who had a severe attack of left frontal herpes. Also the case of a married woman, aged 49 years, who had had frontal herpes 10 weeks before. In the first patient there was extensive ulceration of the cornea and severe iritis, which resulted in corneal and vitreous opacity. In the second patient there was much scarring and ulcerative keratitis with complete paralysis of the third, fourth, ophthalmic division of the fifth and sixth nerves. [J. M. S.]

10.—During the last few years Skirving has seen several cases of secondary syphilis of the throat in which itching of the fauces was a prominent symptom. [J. M. S.]

11.—Payne reports the case of a boy, aged 9 years, who was suffering from a severe attack of whooping-cough. The author irrigated the nose of his patient with 1 to 40 solution of carbolic acid. Ten or 20 ounces of this solution were passed through the nose three times a day. At first, the irrigation caused a good deal of sneezing and coughing and the ejection of a considerable amount of gelatinous mucus, some of which was greenish in color. After the operation had been performed a few times there was less discomfort and the patient looked forward to the injection as bringing relief from his suffering. The cure was complete in about a week, but the treatment was continued a few days longer in order to prevent the recurrence. [J. M. S.]

9. The Respiratory Movements of the Precordial Area in Health and in Disease. J. AIKMAN.

1.—Morris delivered a clinical lecture at the Medical Graduates' College and Polyclinic on January 9, 1901, On eczema in relation to age. He classifies the subject as follows: Eczema in the infant; eczema in the young child; eczema in puberty; eczema in the adult; eczema in the adult woman at menopause; and eczema in the aged. [F. J. K.]

2.—T. Lauder Brunton writes on the action of arsenic as observed during the recent epidemic of arsenic poisoning. He gives a short classification of the symptoms and states the manner in which the general action of arsenic upon the body is brought about. It appears that arsenic interferes with the normal metabolism, but the exact nature of the chemical changes which occur is not understood. Arsenic, while beneficial in very minute doses, in sufficiently large quantities is able to produce inflammation in any part of the body, either applied directly or through the circulation. The stomach may be irritated by direct action, or after the arsenic is absorbed the stomach may become the seat of inflammation from the arsenic in the circulation. The arsenic in the circulation reaches all tissues. Almost all of the symptoms are produced by the action of the irritant in this manner. The author states that there can be little or no doubt that the cause of the recent Manchester epidemic was due to arsenic, because there was

an absence of any other sufficient cause; sufficient arsenic was discovered to produce the symptoms of poisoning; and that the symptoms were identical with those produced by chronic arsenic taken in other ways. Reference is also made to the discovery of selenium in beer, by Dr. Tunncliffe, as being the factor which is partly responsible for some of the symptoms, but before definite conclusions can be arrived at further investigation is required. [F. J. K.]

3.—Will be treated editorially.

4.—Bowlby and Steedman report a case of a woman 27 years of age who was operated upon for perforating gastric ulcer. In addition to the other symptoms the patient had 2 rigors before operation. The perforation was in the anterior wall near the cardiac end. The peritoneal cavity was wiped out with gauze and contained very little foreign material. The patient did well for three weeks when she developed tenderness, distension, restlessness and some temperature. The abdomen was again opened and a volvulus of the small intestine was found in the pelvic cavity. This was relieved and the patient made a satisfactory recovery. The volvulus occurred as a result of adhesions which had taken place within the pelvic cavity. Attention is called to the unusual symptom of rigors after perforation. The temperature here too was unusual reaching at one time 106 while the pulse never was very rapid. [J. H. G.]

5.—Kirk discusses serous vaccinia in connection with cretinism and rickets. The author states that the serous character, occasionally manifested by vaccine lymph, has received very slight consideration in connection with cachectic states, and for that reason he makes mention of this condition which he has observed in 4 cases. [F. J. K.]

6.—Croft remarks that primary sarcoma of the uterus is undoubtedly a very common disease but that in all probability its rarity is considerably overestimated. Such a large number of cases of malignant disease of the uterus come under observation only when the disease is so far advanced that anything more than palliative treatment is impossible and therefore a careful pathological examination of the nature of the growth is not made and it is possible that many of these cases may have been of sarcomatous rather than of carcinomatous malignancy. Williams in his recent book states that his analysis of 2649 consecutive cases of primary uterine neoplasms comprises only two examples of sarcoma to 1571 cancers. He does not state whether these were all confirmed pathologically. Croft records three new cases of this neoplasm, two of which were fatal. [W. A. N. D.]

7.—Russell Coombe reports a case of a boy aged 14 years upon whom he operated for diffuse peritonitis following perforation of the appendix. The abscess here was completely walled off from the upper portion of the abdominal cavity but there was no attempt at walling off below, the pelvis containing a large quantity of dirty brown fluid. The abscess cavity and the pelvis were carefully sponged out and drainage instituted. The appendix was not seen. The patient made a good convalescence except that about two weeks after the operation there developed an abscess of the right tunica vaginalis which was due to a patulous condition of this sac at the time of operation. [J. H. G.]

8.—Broadway, in an article on the uses of diphtheria antitoxin, states that the serum treatment of diphtheria, when used early, practically saves life and has generally placed the prognosis of this disease in a more favorable light. Abscesses may be avoided at the seat of inoculation by using proper antiseptic precautions. Its use should alone be justified by the almost instantaneous relief which follows the injection. The administration of saline solution with the antitoxin probably adds its efficiency. In children the author selects the gluteal or interscapular region for the seat of the injection, and in other individuals he prefers the loose tissues of the breast, unless the child dreads the operation, when he selects the gluteal region instead. In order to secure good results the serum should be used early, freely, and in all doubtful cases. [F. J. K.]

9.—Aikman discusses the significance of the **respiratory movements of the precordial area in health and in disease.** In health the left intercostal space rises and falls at its sternal and, during the respiratory act, to a lesser degree than the right. The respiratory movement does not extend beyond the junction of the cartilage of the rib. In children the restricted respiratory movement extends as high as the second intercostal space, and in adults downwards to the fourth intercostal space. In order to observe this sign the patient should lie flat on his back with his arms along his sides. Deformity of the chest obscures this sign. In acute pericarditis this area of stillness is increased in extent, and the decrease in the respiratory movement is pronounced. This sign precedes the stethoscopic manifestations of pericarditis by a period varying from one to four days. In endocarditis with compensatory hypertrophy of dilatation, the precordial stillness is wider than normal. [F. J. K.]

MEDICAL RECORD.

May 18th, 1901.

1. The Recent Buffalo Investigation Regarding the Nature of Cancer. ROSWELL PARK.
2. Contracture of the Neck of the Bladder. CHARLES H. CHETWOOD.

1.—In an address before the American Surgical Association at its Baltimore meeting, Dr. Roswell Park discussed the recent Buffalo investigations regarding the nature of cancer. His address covers practically the ground gone over by Dr. Gaylor, (See *Philadelphia Medical Journal*, May 4 and May 11, 1901), as to the nature of the cause of the condition and as to the results of the inoculation experiments which were performed on 72 animals. 14 guinea pigs inoculated in the peritoneum with peritoneal fluid containing the organism had an average life of 58 days; 4 inoculated in the peritoneum with cancer mush, an average length of 58 days; 11 inoculated into the peritoneum with dry cancer lymph nodes, 45 days, while 6 guinea pigs inoculated with material from these animals already infected gave an average life of 29 days. This clearly shows the increased virulence obtained by passing the organisms through even one animal. By other experiments organisms grown in a collodion sac within the peritoneal cavity of rabbits were so enhanced in virulence that a healthy rabbit inoculated in the ear vein died within 15 days of general hematogenous infection. The material used for the inoculation was in every case bacteriologically sterile, and consisted essentially of pure culture of the cancer parasite. All these animals rapidly emaciated, and presented on opening the abdominal cavity enlarged peritoneal lymph nodes, and increase in fluid, and enlargement of the spleen. Several also presented minute nodules in the lungs which were considered beginning adeno-carcinoma. Similar nodules were noticed in other instances in the liver and spleen. In all of the organs thus far examined by Plimmer's method large numbers of parasites were found in various stages of development. The lungs in all instances show that the parasites had penetrated the bronchial epithelium, causing a typical proliferation and epithelial nests beneath the basement membrane. Cancer begins as a purely local infection, and kills by becoming generalized. Operation, if done before general infection has occurred, is extremely promising if done thoroughly. Carcinoma as a type of disease, is in every instance an example of epithelial infection. Sarcoma on the other hand is an infection of connective tissue, probably by the same organisms, the tissue cells reacting somewhat differently. It would seem, as far as the investigations have gone, that different forms of parasites have specific tendencies in one direction or the other. [T. L. C.]

2.—Charles H. Chetwood presents a paper on **contraction of the neck of the bladder**, a subject which encroaches upon that of prostatic hypertrophy. Contraction of the neck of the bladder is a fibroid stenosis of the vesicle sphincter, or fibrous infiltration of the glandular and muscular tissue encircling the bladder neck, simulat-

ing symptomatically stone in the bladder and resembling senile prostatic hypertrophy, by producing mechanical hindrance to the urinary outlet. It is commonly, but not necessarily, of gonorrheal origin. The only satisfactory means of treatment, which has been tried, and which has accomplished the end in view, is free incision of the obstructing area through a perineal wound. The author employs an improved instrument in the operation which he describes. 16 cases (the author's own) in which operation was performed, are given. [T. L. C.]

NEW YORK MEDICAL JOURNAL.

May 18, 1901. (Vol. LXXIII, No. 20).

1. The Pathology and Bacteriology of Uretero-intestinal Anastomosis. ROBERT ZEIT.
2. Air, a Factor in Digestion. EDWIN W. MOORE.
3. The Proper Administration of the Schott Exercises. VICTOR NEESSEN.
4. The Use of the Suprarenal Capsule in Diseases of the Heart. Second Paper, with a Report of Cases. SAMUEL FLOERSHEIM.
5. Relations of Vascular Disease to Heart Disease. WILLIAM H. THOMSON.

1.—Zeit concludes in his article on **uretero-intestinal anastomosis** as follows: (1) Ureteral implantation into the rectum is always followed by ascending infection. The resulting pyelonephritis is caused by the *Bacillus coli communis*; (2) The primary mortality is very large, 84 per cent., no matter which operation is done; (3) Of 120 dogs operated upon, 90 per cent. died of peritonitis due to leakage of urine or general sepsis and pyelonephritis during the first ten days; (4) Dogs living a longer time died of pyelonephritis, pyelonephrosis, and pyemia; (5) Dogs which had fully recovered from the operation and the resulting pyelonephritis, and were, to all appearances, in perfect health and vigor again, all had granular contracted kidneys, due to induration and cicatrization of diseased areas. The rectum acts as a fair substitute for the bladder in such cases; (6) Dogs which had fully recovered after unilateral implantation were living by the other kidney. The kidney of the side operated on was atrophic and granular, the result of an early pyelonephritis. The functionally active kidney was of two to eight times the size of the atrophic one; (7) A review of the literature on uretero-intestinal anastomosis in man shows that no better results can be expected in man than in animal experiments; (8) The ureters are frequently dilated, but show very little or no disease, no matter how extensive a pyelitis or pyelonephritis is present; (9) The bladder is always infected by way of the urethra, whether it is emptied at the time of operation or not. A purulent cystitis was found in every case, caused by *Staphylococcus albus* and *Bacillus coli communis*; (10) Artificial immunity to infection by the so-called colon group of bacteria is the only hope of making uretero-intestinal anastomosis a feasible operation. [T. M. T.]

3.—Neesen states that the primary object of the exercises is not to develop the muscles, but to relieve the overburdened heart by (1) drawing blood away from it into the extremities and muscular structures; (2) accelerating the circulation (contraction of the muscles upon the blood-vessels); (3) Soothing the nervous mechanism of the heart by acting upon the motor nerves through the slow movements of the muscles. The rules laid down are as follows: (1) Each movement is to be performed slowly and evenly, without jerking or trembling; (2) Each movement is to be followed by an interval of rest (sitting); (3) Arm movements should alternate with leg or body movements; (4) No exercise should be performed which compresses the blood-vessels or interfere with the breathing; (5) The patient should be instructed to breathe naturally and regularly; (6) The patient should be watched closely for, (a) irregular breathing; (b) straining; (c) trembling; (d) flushing or pallor of face and lips; (e) dilatation of nostrils; (f) yawning; and, (g) drawing down of corners of the mouth. [T. M. T.]

4.—Floersheim observed in using suprarenal powder on a heart and found that the heart became stronger, the pulse became more regular, the blood pressure increased, and a loud, and rough mitral regurgitant murmur became local-

ized, smoother and lessened in intensity, while in some cases the murmur disappeared; (5) a murmur, which owing to the extreme weakness of the heart, could scarcely be heard, became more distinct, thus aiding in the diagnosis; (6) the normal cardiac sounds, when indistinct, became clearer and more easily distinguished; (7) in some cases a rapid pulse became less rapid; in other cases a slow pulse became faster; (8) patients who were very weak, with organic heart disease, were improved; (9) no effect was observed in organic heart disease when the pulse was strong and regular. [T. M. T.]

MEDICAL NEWS.

May 18, 1901. (Vol. LXXVIII, No. 20).

1. On the Modern Treatment of Acute Gonorrhea. GEORGE KNOWLES SWINBURNE.
2. Chronic Gonorrhea. JOHN VANDER POEL.
3. On Gonorrheal Conjunctivitis. WARD A. HOLDEN.
4. Treatment of Gonorrheal Stricture of the Urethra. —JAMES R. HAYDEN.
5. The Treatment of the Complications of Acute Gonorrheal Posterior Urethritis. JAMES PEDERSEN.

2.—Van der Poel describes chronic gonorrhea as one in which as a consequence of previous gonorrheal infection, there exists a secretion containing gonococci, composed of mucus and epithelial cells, manifesting itself (1) either by a drop of muco-purulent fluid at the meatus some hours after urination, or upon pressure, the so-called "morning drop," which may be increased in amount and be present at any and all times; (2) by gluing the lips of the meatus in case there is not sufficient discharge to form a drop; (3) simply by the presence of shreds in the urine, the so-called "clap-threads." He also states that the pathological changes consist of an inflammatory connective tissue formation or hyperplasia characterized (1) by round small-cell infiltration, usually localized about the glands and lacunae, representing, when advanced, the granulations seen in the endoscope; and (2) by an atrophy and shrinking of the new connective tissue with the formation of indurations. The process can be either superficial, a non-stricture forming scar; or deep, involving the cavernous tissues, a true cirrhotic formation or stricture. Anteriorly, this is generally the case, while posteriorly, the same process extends into the submucous tissues, causing swelling of the caput gallinaginis and chronic prostatitis. In addition proliferation of the epithelium and transformation of the cylindrical into flat, both upon the surface and the glands with eventual obliteration and destruction of the latter. [T. M. T.]

3.—The symptoms of gonorrheal conjunctivitis, given by Holden, are as follows: From one to four days after infection, the first signs manifest themselves in a swelling of the lids and in adults a discharge, thin and watery. The lids continue to swell until they become brawny, when eversion is impossible. The conjunctiva of the eyeball becomes edematous and flakes of mucus appear in the discharge, with considerable discomfort. A day or two later a thick, creamy, purulent discharge fills the conjunctival sac, floods the cornea and pours out through the aperture of the lids. At this time the nutrition of the cornea is interfered with and it some times sloughs and breaks down. After the purulent discharge is established, the swelling and tension of the lids diminish, but the conjunctiva remains swollen and velvety from a hypertrophy of its papillae. The parenchyma of the cornea may now become diffusely hazy or superficial ulcers may appear which rapidly extend deep and often lead to perforation of the cornea. The purulent discharge gradually decreases, and in the course of several weeks may cease, but a chronic papillary hypertrophy of the conjunctiva still persists. [T. M. T.]

4.—Hayden considers (1) stricture of the meatus; (2) stricture of the pendulous urethra; (3) the stricture of the bulbous portion, stating that the best routine treatment for recent and even fairly recent cases of gonorrheal stricture, is careful and gradual dilatation, combined with instillations or irrigations, and appropriate diet and internal medication to render the urine bland and non-irritating; if gradual dilatation fails, or for any reason cannot be employed, he then resorts to one of the cutting operations which he describes, being guided in his choice of procedure by the location and extent of the contraction, which is readily ascertained by the *bougie à boule*. [T. M. T.]

1. The Treatment of Psoas Abscess by Incision. ROBERT W. LOVETT.
2. Infantile Scorbutus. JOHN LOVETT MORSE.
3. Neuritis recurring after Atrophy of Both Optic Nerves in a Case of Brain Tumor. EDWARD R. WILLIAMS.

1.—Lovett concludes that fever is not necessarily an accompaniment of psoas abscess formation. When fever does occur the prognosis is not so good as in cases in which it is absent. The best method of operation is by an iliac incision; the next most desirable method is by a lumbar incision. On general principles it seems desirable to put on a plaster jacket almost immediately after the operation so as to enable the patient to sit erect and to enable the abscess to drain almost from the first. [J. M. S.]

3.—Edward R. Williams reports a case of neuritis recurring after atrophy of both optic nerves in a case of brain tumor, in a woman 22 years old. There had been attacks of headache and vomiting followed shortly by failing of vision which was unimproved by glasses. One year thereafter there was marked atrophy of each optic nerve with signs of old hemorrhages about the maculae. Two days before death, which occurred three months later after progressive coma, ophthalmoscopic examination showed typical double optic neuritis worse in the left eye. The literature on the subject is freely referred to. [M. R. D.]

13. Complete Inguinal Extraperitoneal Hernia of the Bladder; Recovery. J. F. BALDWIN.

1.—John A. Wyeth gives the history of hip-joint amputation and the various methods of controlling hemorrhage during its performance. His own method of using the large mattress needles was first employed in February, 1890. After the disarticulation is completed, in order to avoid subsequent oozing from the wound surfaces, it is the author's custom, before removing the pins and tourniquet to thoroughly dry the wound surfaces, to introduce the sutures and to apply a light dressing with a firm gauze bandage. The pins and tube are then removed and the dressing completed. Wyeth finds that this procedure with the elevation of the foot of the bed prevents the extensive oozing which is apt to take place after the operation. He thinks his method of controlling hemorrhage is simpler and safer than the intraperitoneal compression of either the

aorta or common iliac. The article is illustrated by several excellent cuts representing the steps of the operation and there is appended a table of 267 cases of amputation at the hip-joint, where the Wyeth method was used. These are divided into three classes; first, neoplasms, of which there were 137 cases with a mortality of 10.2% second, septic infections, of which there were 94 cases with a mortality of 17%; third, traumatism, with or without septic infection, of which there were 36 cases with a mortality of 63.9%. [J. H. G.]

2.—Robert Sattler in discussing the ocular expressions of intranasal lesions considers two classes. Among the first class are included certain chronic processes which affect the anterior portion of the middle meatus of the nose. Lesions in this region often perplex and disappoint the oculist. Persistent ocular phenomena may exist with symptoms on the part of the nose entirely out of proportion or even negative. Persistent injection of the vessels of the bulbar conjunctivae, distinction of the muscular branches and frequent accompaniment of retrolaral passive edema are some of the clinical expressions of these lesions. The palpebral conjunctiva is generally exempt from this vascular injection. Persistent neuralgic pain is present, and becomes manifest at any continued effort at close work. Pain on pressure can be elicited by passing and pressing the finger against the inner wall of the orbit. Congenital causes or those affecting early life, such as syphilis, rhachitis, scrofula, etc., frequently act as predisposing causes for the obscure intranasal processes and the ocular participations. The second class constitutes those cases where invariably a focal suppuration of the nose is present. The author describes the surgical procedures required in these cases. [M. R. D.]

3.—Vansant gives a brief outline of the pathology, diagnosis, and treatment of the nasal accessory-sinus affections. The most important etiological factors are nasal polyps, deviation of the nasal septum, swelling and thickening of the mucous membrane of the nasal openings of the sinuses, obstruction due to masses of granulation tissue or inspissated mucus. When nasal obstruction occurs pathological changes develop—inflammation or chronic congestion—in the mucous membrane lining the obstructed sinuses. The most prominent symptom, pain in the head, greatly aids in the diagnosis of this condition. The headache varies greatly in intensity, duration, and position; it is usually localized to a definite area. The diagnosis is frequently confirmed by inspection, and transillumination, while at times a valuable aid in the diagnosis, is not always a reliable one. The treatment should be directed so as to provide proper drainage for the affected sinus; the diseased membrane should also be treated. The author highly recommends forcible syringing of the sinuses with dry hot air under pressure. [F. J. K.]

4.—Williams states that a valuable method of reducing the temperature in fevers is the evaporation bath, warm water being used for the bath. Of 15 patients treated by this method there was an average fall of temperature per bath of 1.94°F. The following directions are given: The bath should be given whenever the temperature reaches 102 or 102.5°F.; the patient should lie on a blanket and be covered with one thickness of surgeon's gauze; the gauze should be sprinkled with water having a temperature of 115°F.; the duration of the bath should be guided by the amount of water evaporated. During the interval between the baths the patient should have as little clothing on as possible. [F. J. K.]

5.—Miller reports 11 cases of pelvic inflammation operated upon at Johns Hopkins Hospital, in which the streptococcus pyogenes was found to be the infecting agent. Nine of the 11 cases presented certain features which were indicative of the etiology of the infection. In 6 of the cases the peritoneal cavity was invaded at the operation, and 2 of the patients died. In the other 5 the peritoneum was not disturbed and all recovered. The high mortality in these cases in which the peritoneal cavity was invaded, in contradistinction to the almost uniformly favorable results in celiotomy in which the gonococcus is the infecting agent, should make the operator careful to distinguish between these two classes of pelvic infection. The history is of the utmost importance in making a diagnosis. In the large majority of cases of streptococcal pelvic inflammation the lesion is a parametritis. Of almost equal value with the history is the pelvic examination. The pelvic structures present certain characteristics which are

almost unmistakable. These are the situation of the mass, its consistency, and the intimate connection of the uterus to the walls of the pelvis. In nearly all the cases the streptococcus invades the surrounding tissues through the lymphatics. The parametric exudate lies in a connective tissue surrounding the uterus and vagina and beneath the pelvic peritoneum. It is deep seated, may be situated in either broad ligament, but is usually unilateral. It may lie posterior to the uterus, in the septum between the peritoneal cavity and the vagina, may surround the rectum, or may be ante-uterine, lying between the uterus and bladder. The mass is nearly always asymmetrical. Its consistency is of bone-like hardness. The immobility of the uterus is marked and the exudate can be felt directly from this organ to the pelvic wall. [W. A. N. D.]

6.—Bachmann discusses Meniere's disease and gives a report of a case. The author states that the disease occurs more frequently in the male sex at about the age of 30, and that syphilis and the rheumatic diathesis seem to be the most frequent direct causes. Other important etiological factors are senile changes, leukemia, simple anemia, hemorrhages, serous effusions, cerebral disturbances, parotitis, and influenza. While much of the pathology is still obscure, inflammation with or without hemorrhages is the chief lesion. The cardinal symptoms are vertigo, tinnitus aurium, progressive deafness, and gastric disturbances. Other symptoms are nystagmus, volitional tremor, loss of memory, and weakness of the extremities. The author gives the report of a case of Meniere's disease which occurred in a man, aged 67. The symptoms began 3 years before the patient came under the observation of the author. The patient improved, but not wholly recovered under the treatment, which consisted of the administration of potassium bromide, 7 grains, and hyoscin hydrobromate, 1-200 of a grain, given three times daily for over a month. He was then placed on salicylic acid, 10 grains, and potassium acetate, 5 grains, given three times daily. Pilocarpine injections were used weekly in addition to the salicylate treatment. [F. J. K.]

7.—Conner discusses the financial relations of the medical profession to the people and the public. The author urges that medical men should consider themselves friends, not rivals, and that there should be a better fraternal spirit in our dealings and associations with one another. He advises the establishment of a uniform fee-bill which should be rigidly enforced. Services rendered employes of companies and corporations should be compensated by these companies and corporations. Recognition and compensation for services should be demanded of public authorities. [F. J. K.]

8.—Stoner writes on the etiology and pathology of rheumatism, with special reference to rheumatic diathesis. He concludes that rheumatism is an infectious disease. The variations in the symptoms depend upon the position and the attenuation of the germs. Other diseases, for example, scarlet fever, may at times be complicated by infection of these micro-organisms, thereby causing rheumatic symptoms; he believes that the germs may be situated in the joints, in the heart, and in the muscles. Uric acid and lactic acid are products of the disease. Heredity is an important etiological factor in a large majority of the cases. He maintains that gout and rheumatism, while dissimilar diseases, possess many similar traits, which justifies their being classed in the same group, of diatheses. The author concludes the article with the report of a case of rheumatic fever in a girl, 4 years of age. [F. J. K.]

9.—Mewborn reports a case of acute dermatitis caused by the use of hair-dye. The base of this dye was found to be hydrochlorate of paraphenylene diamine. This dermatitis occurred in a married woman, 44 years of age. The eruption, occurring soon after the use of the hair-dye, covered the forehead, which was red and shiny, with a few vesicles near the margin of the hair, the eye-lids, the ears, the nose, and cheek, and the flexor and extensor surfaces of the forearms. The anterior and inner sides of the thighs were covered with numerous small slightly elevated papules and a few vesicles. The patient complained of a burning sensation and an itching of the face. [F. J. K.]

10.—D. N. Eisendrath discusses the difficulties and dangers of anesthetics. He stresses upon the necessity of observing the pulse rate and tension and the condition of the pupils during anesthesia. A dilated pupil which does not react to light is a sign of the

earliest symptoms of syncope. In case of heart failure during anesthetization the author has found König's method of massaging the heart to give most satisfactory results. It is accomplished by making regular pressure with the semi-closed hand over the heart with the object of stimulating a ventricular contraction. It is useless to give cardiac stimulants before the circulation has been re-established. The author has found that chloroform, as well as ether, will produce albumin and casts in the urine, although in cases of renal disease its effect is much less deleterious than the effect of ether. [J. H. G.]

11.—McLean believes that the vesicular murmur is dependant upon the tidal air imposed upon the residual air, the sound being produced by contraction and distinction of the vesicular walls. The rush of air into the lungs with inspiration stimulates the alveolar walls to contraction and thereby aids in the propulsion of the blood through the pulmonary capillaries. In order to bring about perfect contraction, the proper amount of air must be inspired. Incomplete pulmonary action leads to stasis and transudation of serum into the vesicular and bronchial structures and into the interstitial tissues. Impaired pulmonary function aids in the formation of the proper soil for the development of tuberculous infection. Any imperfect pulmonary function interferes with the production of the vesicular murmur. In the treatment of imperfect function, measures should be adopted that tend to strengthen the respiratory movements. The author holds that too much stress has been laid upon diagnosis by the aid of the microscope, and that of more importance is the absence of muffling of the vesicular murmur. He believes that the principle, governing the action of the pneumatic cabinet, is correct, and that this measure is indispensable in the treatment of many cases. [F. J. K.]

12.—Thomas R. Brown disposes of the former theories regarding the formation of renal calculi as unsatisfactory and submits a number of cases which go rather to prove the more recently advanced theory of the bacterial origin of calculi. In each case which he reports there was previous to operation a careful analysis made of the urine from each kidney obtained by ureteral catheterization. From the urine thus obtained cultures were made and in all cases excepting one the urine from the supposed healthy kidney was found absolutely normal, while from the diseased side were obtained various cultures. The reaction of the urine from the infected side depended entirely upon the variety of micro-organisms met with, being acid in one case, due to the colon bacillus, and alkaline in 5 cases in which there were found various micro-organisms possessing an ability to decompose urea. In 5 instances, where the urine was alkaline, nephrectomy was performed and the stone examined in each case. In 3 cases bacteria were found in the center of the calculus; in 3 other cases the stones were not examined. In only one case was the urine acid and here the micro-organism found was the *B. coli communis*. [J. H. G.]

13.—J. F. Baldwin reports an interesting case of hernia of the bladder. The patient was a man aged 51 years, weighing 245 pounds, who had suffered from an inguinal hernia for 8 years, which he was unable to retain with a truss. It was difficult at times to completely empty the bladder unless the hernia were elevated. When seen by Baldwin the hernia had been irreducible for about 48 hours. There were no symptoms of intestinal obstruction, but there was considerable pain and tenderness. A diagnosis of omental hernia with probably some involvement of the bladder was diagnosed. When operated upon it was found that the hernia consisted entirely of the bladder without any peritoneal covering. Because of the patient's obesity reduction was difficult, but ultimately the patient made a good recovery. Baldwin's case is the 11th to be recorded of hernia of the bladder only. [J. H. G.]

LA SEMAINE MEDICALE.

Februara 27th, 1901.

1. Operative Treatment of Balanitic Hypospadias. F. de QUERVAIN.
2. A Practical Means of Differentiating Human Blood from that of Animals. L. CHEINISSE.

1.—De Quervain describes the operation first employed by Beck of New York and independently by von Hacker. A Y-shaped incision, almost approaching a T-shape is made

upon the under surface of the glans. The straight portion of the incision being parallel to the urethra which is carefully dissected out. Then the operator has the choice of two procedures; either to make an incision in the line of the urethra in the head of the penis, practically grooving the head for the purpose of placing the urethra in this groove and then covering it in with the two flaps of the head, made by the surgeon in forming this groove, and fastening it there. The parts thus fashioned approximate the normal penis; or the operator may pass a straight bistoury from the position of the proposed meatus, tunnelling through the head. If this course is chosen a pair of forceps inserted through this canal may be used to bring the urethra, previously dissected out, into its proper position. The article is well illustrated and the author closes with a brief outline of post-operative treatment. [T. L. C.]

March 6th, 1901.

1. Severe Vomiting Complicating Pregnancy. CH. ACHARD.
2. The Value of the Presence of the *Bacillus Filiformis* in the Stomach in the Early Diagnosis of Cancer of that Organ. H. EHRET.

1.—Pregnant women frequently suffer from vomiting which can neither be classed as simple nor yet pernicious in form. In this variety of cases the spells are frequent and occasion great distress, but they are by no means uncontrollable. Achard classifies the condition according to its amenability to treatment. In his first case cited the patient was a young woman of 26 years, pregnant 3 months and had vomited from the sixth week. She was of hysterical temperament. The patient improved rapidly upon a mixture of equal parts of bicarbonate of soda and magnesia, taken in teaspoonful doses whenever the pains appeared. She was also placed upon an absolute milk diet. This patient was a sufferer from hyperchlorhydria. His two other cases mentioned were also of nervous taint but hyperchlorhydria was not present. In the second case the alkaline treatment was of no avail; nor did other remedial measures employed prove beneficial. Lavage was finally resorted to, and while at first the spasms of vomiting increased, after 14 washings the stomach symptoms quite disappeared, and the patient rapidly gained in weight. His third case was similar to the one just mentioned and was also cured by lavage. There was a decidedly neurotic factor in this case also. Achard believes that hysteria may play an important part in the development of this condition. There may be in these cases a hyperexcitability of the vomiting center, easily disturbed by reflex influences from the stomach itself as well as the sexual organs. [T. L. C.]

March 13th, 1901.

1. The Pathology Treatment of Obesity. DEBOVE.

1.—Debove considers obesity as a disease of the nervous system, either primary or secondary. It may be called primary when the cause is not discoverable, and secondary when it develops under the influence of an easily established cause such as gout, diabetes, chlorosis, the menopause, myxedema, arrest of development of the testicles, etc. The quantity of food ingested is not by any means proportionately adapted to the needs of the organism. We know that the needed quantity is utilized and the excess destroyed by processes of oxidation. If there was a total absorption by the economy of the ingested food there would be a steady increase in size. There must be a regulating force in the nervous system which moderates combustion and maintains bodily equilibrium during periods of fasting. Obesity is caused by the derangement of this nervous center. Its treatment comprises 2 periods. The first of which Debove calls the period of insufficient alimentation; and the second the period of voluntary regulation. No cure can be brought about unless the patient is willing to assist by carrying out the dietetic measures conscientiously. Debove determines the amount of food necessary to the body weight by the establishment of the thermic value of food. For instance, if we wish to determine this quantity in a

kilo. are required in a state of rest, and the simple multiplication will give us the number of calories necessary for the sustenance of this man. Physiology furnishes us with the thermic value of various foods, and we can so arrange the patient's alimentation that he receives whatever proportion of the 3010 necessary calories which we desire to give him. A sample diet upon which a patient lost 53 kilos in less than 5 months, is as follows: For breakfast, a cup of tea or milk; mid-day meal, one or two slices of meat, a few vegetables or a little salad, a hundred to a hundred and fifty grams of bread, a little cheese, fruits as desired, and a cup of black coffee without sugar. For supper, a glass of hot milk, sweetened, 30 to 50 grams of bread and fruits as desired. He believes that this treatment is best carried out in a sanatorium and that above all the patient should not eat at table with the family. Exercise is not of any special value in the treatment of obesity for the reason that it causes an increased appetite, which will more than compensate in weight increase for the amount lost. He believes that mineral waters are apt to produce serious digestive disturbances. Thyroid feeding is of value only in those cases in which myxedema can be regarded as a cause. He has observed serious dangers arising from thyroid treatment, and in one case sudden death of the patient. The principle upon which Debove's treatment depends is that we shall supply the deranged automatic control of the nervous center by voluntary control, and so induce the proper regulation of body weight. [T. L. C.]

5. On the Excision of the Retrotarsal Fold. N. A. KAN.
6. A few Words on the Question of Heredity of Tuberculosis. E. E. MILLER.

1.—Will be abstracted when completed.

2.—Krawkoff has made an exhaustive investigation of the physiological effect of johimbin, an alkaloid first isolated by Spiegel from the bark of the tree *jambehou* which grows in South Africa. An infusion of the bark is very popular among the natives as an aphrodisiac, and the alkaloid has been claimed to possess marked aphrodisiac properties, almost approaching a specific action. Among the observers who classed this new drug with the very best and safest of the aphrodisiacs were Oberwarth, Loewy and Mendel. The experiments performed by the author show that on frogs johimbin exerts a paralyzing effect. At first the cerebrum, then the respiratory center and finally the spinal cord are affected. The heart's action stops owing to the paralysis of the cardiac ganglia; this being followed by paralysis of the cardiac muscle. The general paralysis is preceded by a brief period of excitement. On rabbits, the same effects are produced. After a brief period of stimulation characterised by excitability and increased respiration there develops general paralysis of the central nervous system. The temperature is markedly lowered owing to the paralysis of the vasomotor and consequent increased radiation. The pronounced antipyretic action of johimbin was demonstrated on rabbits as well as birds, the fall of temperature amounting to 1-2 degrees. Owing to the vasomotor paralysis, the penis becomes greatly overfilled with blood. This engorgement of the blood vessels may lead to occasional erections, but the latter are not brought about by a stimulation of the sexual centers. In dogs the same effects were observed. Six physicians having offered themselves for experiment, the drug was also tried on them. Some of them suffered from partial impotence as a result of neurasthenia. In one 10 drops of johimbin taken on an empty stomach produced dizziness, disturbance of locomotion, nausea, sweating,

sensation of heat, engorgement of the conjunctiva and migratory pains. A general mental depression, inability to concentrate the mind, aversion to work and weakness added to the disagreeable effects of the alkaloid. There was not the least indication of any specific effect on the sexual centers. In the second case 10 drops after a light breakfast produced heaviness in the head, irritability, nausea, salivation, fainting sensations, a feeling of heat in the abdomen, engorgement of the conjunctiva and slight flow of tears. Such a wretched state of the mind was produced that the doctor did not care to continue the experiment. No effect on the sexual center was observed in this case; on the contrary, the last sparks of sexual desires were completely extinguished. Similar effects were observed in the third case, while in the rest the manifestations were much milder. In neither was any aphrodisiac action noticed. On the ground of his experiments on animals and observations on man the author comes to the conclusion that johimbin possesses no aphrodisiac properties whatever, and, moreover, it is not an altogether harmless drug. [A. R.]

3.—Krimoff reports a case of invagination in a soldier 24 years old. The diagnosis was established only 7 days after the onset, and an operation performed about 5 weeks later. In the meantime the patient suffered from repeated attacks of severe abdominal pains and obstipation which could be relieved with difficulty by calomel and high enemas. The suffering becoming unbearable, the patient agreed to an operation. A laparotomy disclosed an invagination of the cecum and ascending colon into the transverse colon, bringing the end of the ileum close to the latter. Owing to the numerous adhesions formed, the removal of the invaginated gut could not be accomplished and intestinal anastomosis between the ileum and the descending colon was performed. Convalescence was complicated by bronchitis and suppuration, but the patient finally made a complete recovery. Indican was present in the urine in excess before the operation, disappearing entirely after it. [A. R.]

4.—Kalabin reports a case of a primipara, 36 years old, in whom pregnancy was complicated by two uterine fibroids. Gestation was frequently interrupted by threatened abortion which was prevented by the use of rest, opium, *viburnum prunifolium*, hot compresses and bromides. The woman was finally delivered of a healthy child, the labor having lasted for 34 hours. When examined a year later, the uterus was found somewhat enlarged, one of the fibroids much smaller in size, while the other disappeared entirely. [A. R.]

5.—Kan points out the excision of the retrotarsal fold as the best method of treating trachoma. The operation has always proved successful in his hands and can be performed without difficulty. Some points in the technic of the operation are discussed. [A. R.]

6.—Miller asks whether the facts in every-day life substantiate the universal claim that tuberculous parents transmit a predisposition to the disease. He answers this question by presenting in a tabulated form data obtained from 71 cases of tuberculosis. The table shows that in only 11 was there tuberculosis in one or both parents. In the other 60 the disease was evidently acquired. All these cases occurred in well to do families, and there can, therefore, be no suspicion of even an acquired predisposition. In other words, these were cases of primary infection. Admitting that tuberculous parents may transmit to their offsprings a special vulnerability of the cells, there is no reason to apply this transmission specifically to tuberculosis. Such persons are susceptible to any other infectious disease. Again, tuberculosis is more apt to run in families not so much on account of the so-called heredity but owing to the direct or indirect exposure to infection which the various members of the family suffer. The author makes a plea for restrictive measures on the part of the individual, society and the state. He emphasizes especially the necessity of cleanliness, as a preventive measure. [A. R.]

THE SURGICAL TREATMENT OF CHRONIC ULCER OF THE STOMACH.

By A. W. MAYO ROBSON, F. R. C. S.,

of Leeds, England.

Senior Surgeon to the General Infirmary at Leeds, Emeritus
Professor of Surgery in the Yorkshire College
of the Victoria University.

Mr. President:—

I must first thank you, sir, most sincerely for the kind invitation which you, personally, and the Council of the American Surgical Association have extended to me in asking me to take part in your proceedings, an honor which I very highly appreciate. The subject of the "Surgical Treatment of Ulcer of the Stomach" is one that has for some time, and is now, attracting the attention of surgeons all over the world, so that I hope I shall need to make no apology for ventilating my views on its treatment before this important Surgical Association.

The treatment of gastric ulcer is at first essentially medical, and when properly carried out and for a sufficient length of time it is usually completely successful. Leube says that one-half or three-fourths of all cases will be cured by 4 or 5 weeks of treatment, but that if not cured in that time they will not be cured by medical treatment alone, a view in which I thoroughly concur. Unfortunately, however, in many cases, treatment is stopped as soon as relief to pain is obtained and long before the ulcer is healed. In some cases this may be due to the uncertainty of diagnosis or from the impatience of the patient; perhaps in others, to ignorance as to how long it takes to secure the healing of a gastric ulcer. The earlier in the course of the disease, that radical treatment, in the shape of dieting and rest, is adopted, the less prolonged will the treatment need to be and the more likely is it to be effectual; but probably the very earliest time that a patient should be allowed to be out of bed is from a fortnight to a month after all pain and tenderness have disappeared.

Failing this thorough treatment, relapses will be certain to occur, and in the long run complications will supervene or the ulcer will become chronic, when, though medical treatment may relieve in some cases, cure can only be looked for, in the greater number, by surgical methods.

In considering the treatment of ulcer of the stomach, it is useful to hold in view the course of an ulcer of the leg, which, directly the healing stage has arrived, becomes free from pain; but this neither indicates that healing is completed nor that care may cease, and should treatment be abandoned and the ulcer become chronic, though it may even then be painless, it is at any time liable to become inflamed or to extend; moreover, the surrounding tissues become infiltrated with lymph which tends to organize, and this in a hollow viscus soon ends in stricture, as in the leg it tends to drag on the surrounding skin and produce constriction of the limb.

The surgical treatment of intractable or relapsing gastric ulcer is in the greater number of cases the only satisfactory method of dealing with these re-

fractory cases, and operation should be resorted to at a much earlier period than has hitherto been the custom; and always before the patient is so far reduced by pain and starvation or the supervention of serious complications that weakness and anemia render any operative procedure hazardous.

Ulcer of the stomach is a much more serious matter than is generally recognized, for, according to various authors it has a mortality, when treated by general and medical means only, of from 20 to 50 per cent.

Dr. Einhorn, in his well known work on Diseases of the Stomach (p. 223), says: "At first glance it would appear that the prognosis of gastric ulcer is quite good, especially nowadays, when the diagnosis of the affection is usually made at an early date. However, if we take into consideration the tabulated statistics given by Debove and Rémond (p. 276), in reference to the outcome of all cases of ulcer, we become more careful in our favorable predictions. This table gives in a hundred cases of ulcer:

Perfect cure	50
Perforations and peritonitis	13
Foudroyant hematemesis	5
Pulmonary tuberculosis	20
Inanition	5
Different complications	7

The excuses of a few years ago that there is a great responsibility in recommending surgical treatment either from the uncertainties of diagnosis or from the risk of operation, can no longer avail, since the diagnosis of gastric ulcer, thanks to the researches of Ewald, Hemmeter, Einhorn and others, has been brought to a greater state of perfection than exists in many other obscure diseases, where radical treatment has to be adopted on much more slender foundations; and, fortunately, now that the mortality in operations for simple diseases of the stomach, including perforation and hemorrhage, has been reduced in the hands of experienced surgeons to about 5 per cent, the great risks of surgical treatment cannot be advanced even by its most ardent opponents.

We have to consider, not only the treatment of gastric ulcer itself, but also that of all its complications, which are no less numerous than serious, and before describing each separately, it may be well to name them collectively. They are as follows:

1. Local peritonitis or perigastritis, ending in adhesions.
2. Local peritonitis ending in suppuration and a localized abscess.
3. Subphrenic abscess.
4. Abscess of liver, pancreas, or spleen.
5. Fistula between the stomach or pylorus and adjoining organs, or with the surface of the body.
6. Acute perforation of the stomach wall.
7. General peritonitis.
8. Hematemesis and melena.
9. Dilatation of the stomach.
10. Tumor of the stomach or pylorus.
11. Cicatricial stenosis of the pylorus.
12. Hour-glass stomach.
13. Spasm of the pylorus producing intermittent narrowing (Reichmann's Disease).

14. Atonic motor deficiency.
15. Severe gastralgia.
16. Persistent vomiting.
17. Tetany.
18. Acute or chronic pancreatitis.
19. Profound anemia resembling the pernicious form.
20. Pressure on or stricture of the bile ducts with jaundice.
21. Catarrh of the gall-bladder from adhesions producing attacks like those of cholelithiasis.
22. Great loss of flesh and strength, ending in phthisis.
23. Cancer secondary to ulcer. "Ulcus carcinomatosum."

We are not prepared to subscribe fully to the views of Tricomi (*Riforma Medica*, 1899), who draws a parallel between the treatment of hernia and that of ordinary gastric ulcer, and proposes that as hernia is treated radically with success, so gastric ulcer should be treated radically by the performance of gastro-enterostomy. Heydenreich (*Sem. Med.*, Feb. 2nd, 1898) argues: "The death rate from all cases of gastric ulcer is from 25 to 30 per cent., but from gastro-enterostomy, only 16.2 per cent.; therefore, the operation has less danger than the disease."

The question of medical versus surgical treatment in this class of cases is, however, one that can be much simplified by a careful study of statistics.

At the time I delivered the Hunterian Lectures, in March, 1900, I had been able to collect from various sources 188 operations on the stomach for gastric ulcer (excluding those for perforation and hemorrhage), of which 157 recovered and 31 died, thus giving a mortality of 16.4 per cent. These included 34 personal cases.

Now, although the deaths from gastric ulcer medically treated, averaged 25 per cent., taking a low estimate, and those from even the worst and most inveterate cases of ulcer when treated surgically, only 16 per cent. at the time of those lectures, yet, the difference did not then appear so great as to make it desirable or prudent very strongly to advocate surgical treatment until the disease had become chronic, or until serious complications had ensued.

To-day, however, the facts are very materially altered by the all-round improvement in operations on the stomach, and the contrast of 25 per cent. of deaths in cases treated medically and 5 per cent. as shown in our latest statistics in those treated surgically, in the worst and most complicated cases, is so striking, that we feel it incumbent to urge most strongly, that although cases of gastric ulcer should first be submitted to medical treatment, yet, if such treatment fails to cure in a reasonable time, or if relapses occur on the resumption of solid food, then medical should give place to surgical treatment: for it is unfair to the surgeon to hand over to him almost moribund cases, and it is unjust to the patients to persist in dosing them with medicine, or otherwise treating palliatively, cases that can only be benefited or cured by surgical means.

Operative Treatment.—Before the abdomen is opened, it is quite impossible to say what operation or operations will be required, and the surgeon must be prepared to adapt himself to circumstances on discovering the position of the ulcer and

the conditions associated with it, especially as to the presence or absence of adhesions and other complications.

Any one of the following operations, or a combination of one or more, may be called for in each individual case: *Exploratory Gastrotomy*; *Gastro-enterostomy* to secure physiological rest to the stomach and relieve the hyperchlorhydria, or, in other cases, to short circuit a stenosis; *Excision of the ulcer*; *Pylor-rectomy*; *Pyloroplasty*; *Gastro-plasty*; *Gastro-Gastrotomy*; *Gastrololysis*; *Pylorodiosis*; *Gastroplication*.

The Preparation of the Patient.—It has been the custom with many surgeons to put stomach patients through a long course of preliminary treatment, such as frequent lavage of the stomach and abstinence from food before operation; this, as a rule, is quite unnecessary and certainly inadvisable in the greater number of cases, first, because the treatment is depressing and debilitating in the case of patients already exhausted by a long illness; secondly, as proved by Dr. Harvey Cushing's bacteriological investigations, the stomach contents speedily become aseptic if the mouth be cleansed and aseptic foods administered, and thirdly, as proved by ample clinical experience, elaborate preliminary treatment is unnecessary to success.

If the stomach is greatly dilated and the contents are foul, then lavage with simple boiled water night and morning is adopted for two days before operation. The careful cleansing of the mouth and teeth and the administration of foods sterilized by boiling is advisable. The last meal is given the night before, about 12 hours, the stomach is washed out about two hours, and a nutrient enema given about an hour before operation.

In other cases no lavage is adopted, but the same care is exercised in cleansing the mouth, giving sterilized food and administering a nutrient enema consisting of 1 oz. of brandy, 1 oz. of liquid peptonoids, and 10 oz. of normal saline solution. Every patient is enveloped in a suit of cotton wool made by the nurse out of Gamgee tissue, and each has an injection of 10 minims of Liquid strychnia B. P., administered subcutaneously before the operation is begun. The preparation of the skin and other aseptic details of the operation differ in no respect from those observed in operations generally.

Exploratory Gastrotomy, or opening the stomach by a free incision of its anterior wall, is an operation occasionally called for in the surgical treatment of ulcers.

(a) In order to verify the diagnosis of ulcer when there is so much thickening of the stomach walls as to suggest the presence of cancer.

(b) When, although the symptoms have pointed to ulcer as the cause of the gastric trouble, the stomach, on exposure, betrays no evidence of puckering or other characteristic signs, and when in order to verify the diagnosis and ascertain what is best to be done, it is felt desirable to examine the interior of the organ.

(c) In certain cases of gastrorrhagia, it is desirable to perform exploratory gastrotomy in order to find and ligature the bleeding vessels or to otherwise arrest the hemorrhage.

(d) It necessarily forms part of any operation for the excision of ulcer of the stomach.

It is not necessary for me here to enter into any

detailed description of the operation, which must be so familiar to all my hearers, and which requires to be varied according to the object in view. The following are examples of exploratory gastrotomy for ulcer:

Man aged 38. Symptoms of chronic ulcer extending over several years; on exposure of stomach no evidence on surface to indicate accuracy of diagnosis; exploratory gastrotomy; discovery of large ulcer $1\frac{1}{2}$ inches by 3 inches on posterior wall of stomach; posterior gastro-enterostomy; recovery.

Acute gastrorrhagia; no evidence on exposing stomach; exploratory gastrotomy; numerous bleeding ulcers seen, two of which were bleeding freely and were ligatured 'en masse'; gastro-enterostomy; recovery.

Excision of the Ulcer is, as a rule, unnecessary, but not always to be avoided, as in some cases of bleeding ulcer, and in others where the thickening and induration render it difficult to decide on the absence of malignant disease; this was the case in a man of 54 on whom I operated in 1891, when, finding the pylorus the seat of diffuse induration, excision of the whole indurated area was performed successfully. A careful examination of the removed mass showed that the growth was inflammatory around a chronic ulcer.

In another middle-aged man in whom the diffuse induration was suggestive of cancer, the pylorus was opened and a deep ulcer on the posterior wall successfully excised, the edges of the original incision as well as the margins of the posterior wound being brought together in a direction transverse to the axis of the pylorus over a bone bobbin, as in the modified operation of gastro-enterostomy.

Rydygier prefers excision of the ulcer to gastro-enterostomy, because he believes that carcinoma not infrequently develops in the scar of an old ulcer.

It is impracticable to give any specific description of the operation of excision of an ulcer, seeing that the procedure will vary according to its size and position.

After excision of an ulcer, the bleeding from large vessels must be controlled by ligature, but the oozing from the smaller vessels will be stopped readily by the continuous suture employed to bring together the edges of the wound. If the excision involve the serous coat, a Lambert's continuous stitch with a silk or celluloid suture will be necessary. Should the excision have been near the pylorus, the line of suture must be placed transversely to the axis of the canal so as to avoid stricture.

The following cases are examples of gastric ulcer treated by excision:

Ulcer of Pylorus, Stenosis, Dilatation of Stomach, Excision of Ulcer and Pyloroplasty.

John W. R., aged 38, admitted to the Leeds Infirmary with the history of stomach trouble for thirteen years. Pain after food and vomiting were the initial symptoms. Severe hematemesis occurred 6 years after the commencement of symptoms. Great loss of flesh and weakness were followed by inability to work, although he had stomach lavage and other appropriate treatment. On admission the patient was very thin and profoundly weak. He weighed 8 stones. A swelling could be felt below the right costal margin. The stomach reached three inches below the umbilicus and there was visible peristalsis. Free HCl present. Operation November 15, 1900. The pylorus was found much thickened, forming a nodular swelling adherent to the gallbladder and liver and to the abdominal wall by omental adhesions. After separating the adhesions a small perforation was discovered in front of the pylorus evidently the site of a perforation which his medical man who was present said he remembered occurring

some months previously and which was then treated successfully by rest and rectal feeding.

The pylorus was freely laid open and found to be the site of a round perforating ulcer in front and another on the posterior wall; the latter had perforated into the substance of the pancreas; both were excised thus practically constituting a pyloroplasty. The edges of the posterior wound were brought together transversely to the axis of the stomach. The anterior wound was prolonged into the duodenum and stomach and its edges were brought together transversely to the axis of the stomach over a bone bobbin, thus leaving a capacious channel between the stomach and duodenum surrounded by healthy mucous membrane.

Recovery was uninterrupted and he was discharged on December 12th, weighing 8 stone, 5 pounds.

On January 9th, 1901, he returned to report himself well and then weighed 9 stone, 11 pounds.

Pyloric Ulcer Treated by Excision of Ulcer and Pyloroplasty.—Mrs. M. K., aged 44, well till two years ago, when she had colic and loss of flesh. Under treatment recovered and regained some of lost weight. September 15, '97, recurrence of attacks similar to that of a year before, but with pain at the right side over the pylorus. Loss of weight and strength. The patient had for some time been an invalid and had been continuously under medical treatment for months. Her weight was 6 stone, 11 pounds. There was visible peristalsis towards the pylorus, which was fixed to the gallbladder; no pain or tenderness. Liver 2 inches below costal margin but no nodular, and no jaundice present.

Operation 23.7.98. An ulcer at the pylorus was found adherent to the liver, which formed its base. Stenosis of pylorus. Pyloroplasty performed after excision of ulcer, the opening being sutured transversely over a bone bobbin.

3.12.98. Had gained 1st, 8 pounds in weight. No trouble in digesting anything.

23.12.99. Reported as "very well" and of normal weight.

The operation of Pyloroplasty for ulceration of the pylorus may be conveniently mentioned under the heading of excision of ulcer. Dr. Rodman (*Philadelphia Medical Journal*, June 9, 1900) has collected from literature and personal correspondence, detailed reports of 40 pyloroplasties, partial gastrectomies and excisions for ulcer, with 6 deaths. This includes cases since 1881, but later operations under improved technique contrast favorably with the earlier ones. I have myself performed the operation of excision of gastric ulcer 6 times, all the patients recovering.

Nevertheless, the mortality after excision will probably always be higher than the more simple operation of gastro-enterostomy. The more severe and radical operation should, therefore, be reserved for cases that are not suitable for the less severe operation, or in which the suspicion of cancerous degeneration is entertained and cannot be disproved on naked eye inspection. The following case is an example:

Tumor of Pylorus and Chronic Hematemesis due to ulcer. In 1891 I was asked by a medical friend to see a man of 54, who for 6 months had suffered from pain coming on an hour after food, and more recently from vomiting blood of coffee-ground character in considerable quantities, so that he was not only reduced in flesh and strength, but had also been rendered profoundly anemic by the loss of blood.

A tumor of the pylorus could be easily felt, and the stomach was markedly dilated.

As he was rapidly losing ground an operation was performed, and the pylorus was found thickened and nodular, with adhesions to the liver and omentum.

After separating the adhesions, the pylorus was excised and the open end of the duodenum was fixed to the opening in the stomach by means of two lines of sutures without the use of a bobbin, the rest of the stomach aperture being closed by a double layer of sutures. The tumor proved to be inflammatory around an open ulcer, which had been the source of the hemorrhage. The bleeding was not repeated, and the patient rapidly gained flesh and returned home within the month.

The subsequent history of this case is interesting on account of cicatricial contraction of the new pyloric aperture which led to the invention and employment of a decalcified bone bobbin to act as a temporary splint over which to apply the sutures and thus to secure a large aperture which has little tendency to contract.

Gastro-enterostomy, in the absence of special complications, is the operation to be relied on in the treatment of ulcer of the stomach; it acts by securing physiological rest by means of drainage, thus allowing the ulcer to heal without being subjected to the irritation of acid secretion, accumulation of food, or frequent stomach movement. It also, while remedying the hyperchlorhydria, relieves pyloric spasm, and while preventing stagnation of fermenting fluids, materially diminishes gastric dilatation. The posterior operation is the one I personally prefer, the junction of the posterior wall of the stomach with the first part of the jejunum being effected by two continuous sutures with or without a decalcified bone bobbin. The use of a bone bobbin not only secures an ample and immediately patent opening between the two viscera for the passage of the stomach contents, but protects the line of union from the irritation of the stomach contents.

The whole operation can be easily completed in half an hour, and it may even be done in half the time. Along with my colleague, Mr. Moynihan, I have given my full experience of the operation and of stomach surgery in general in book form, now in the hands of the publishers, Messrs. Baillière, Tindall & Cox.

Our experience with the posterior operation has been very favorable, not only in the rate of recovery of the patients, but in the smoothness of the recovery, many of the patients recovering without even once vomiting, and only on two occasions have we seen regurgitant vomiting of bile, which in the anterior operation is much more frequently seen and at times becomes serious or even leads to a fatal issue.

We have performed the posterior operation on 40 patients with two deaths, or an average mortality of 5%, but as the deaths were from more or less accidental causes which should be avoided in the future, and occurred respectively on the 10th and 11th days after operation, during the whole of which time the patients had been able to take and assimilate food, the gastro-enterostomy "per se" cannot be blamed for the result, which might under similar circumstances have occurred after any operation.

Dr. Fantino (*Archiv. fuer Klinische Chirurgie*, xlii, 1 and 2) examined Professor Carle's cases of gastro-enterostomy as regards the following points:

(1) Changes in the peristalsis of the stomach.
(2) The ability or non-ability of the new sphincters to close the outlet.

(3) The capacity of the stomach.

(4) The secretion of hydrochloric acid.

In the cases examined, the operation immediately improved the peristaltic power of the stomach, though it did not render it normal. The stomach could generally empty itself, but did so gradually. Systematic examinations of the stomach contents were made after test-meals, etc., and showed that after an irregular period the stomach regained completely its power of emptying itself; in fact, as a rule, after gastro-enterostomy the stomach would be found practically empty in three to five hours after a meal.

Generally it was found that the stomach decreased in size soon after gastro-enterostomy, so that the formerly distended organ became normal in size. Examinations of the stomach by means of distension with carbonic acid and by other methods showed that a sphincter was developed at the new opening, and that its power increased with time. The secretion of hydrochloric acid after operation was studied: In cases where there was formerly hyperacidity, this condition was lost, and though the degree of acidity in any individual case varied from time to time, yet these variations did not depart from physiological limits. In the same examinations it was found that regurgitation of bile into the stomach took place, but it was of no importance so long as the outlet from the organ was sufficient. Cases of hypo- and anacidity showed no change in their gastric juice after operation, showing clearly that this condition is not dependent on obstruction, but on previous changes in the mucous membranes, these changes being probably in the nature of an atrophy of the peptogastric glands.

The following cases are given as examples of the treatment of gastric ulcer by gastro-enterostomy:

CASE 1.—Mrs. W., aged 32, pyloric ulcer treated by pyloroplasty, with subsequent contraction. Gastro-enterostomy (anterior). Pyloroplasty during active ulceration of pylorus in December, '95. Great relief for a time, but later recurrence of dilatation, vomiting, pain, and other symptoms. Very considerable loss of flesh. Patient thin and anemic; pulse feeble and rapid; marked dilatation of the stomach reaching well below the umbilicus.

4.10.98. Operation. Gastro-enterostomy, (bone bobbin employed). In October, 1899, patient well and active. February, 1900, had gained 1 stone, 10 pounds.

CASE 2.—Mr. M. A., aged 28. Pyloric ulcer, tumor of pylorus, gastro-enterostomy. (Anterior). Two years ago weighed 12 stone, 12 pounds (now 9 stone, 6 pounds). Pain 2 hours after food. For last two months vomiting on an average 5 times a week, twice coffee-ground vomit. Enormous dilatation of stomach. Pyloric tumor movable, visible peristalsis.

4.8.99. Operation. Large mass at pylorus evidently thickening due to active ulceration, glands large but not matted. Gastro-enterostomy. (Bone bobbin used).

27.8.99. Good recovery. Weighs 9 stone, 7 pounds.

20.9.99. Weighs 10 stone, 13 pounds. Can eat anything. Well, 1901.

CASE 3.—Mr. D. B., aged 31. Extensive ulceration of stomach with large tumor. Gastro-enterostomy (anterior). Dyspepsia 17 years. More severe last 20 months. 16 months ago vomiting recurred and from the outset large quantities ejected but never containing blood. Recurrence occasionally of similar attacks always relieved by treatment. December, 1897, stomach reached pubes and visible peristalsis seen. Relief followed dieting and lavage till March 1898, since which time pain almost constant. Pain not materially worse after food, nor relieved by vomiting. Loss of weight from 10 stone to 8 stone, 6½ pounds. Great feebleness.

6.5.98. Operation. Large irregular tumor at pylorus and along lesser curvature, but glands though large, dis-

crete. Gastro-enterostomy, bone bobbin employed. 8 stone in weight when he left the Home, 7.6.98.

17.8.98, weighs 9 stone, 3 pounds. Letter dated 12.2.1900, to say: "My health continues perfect. I have not lost a day's work through illness since I recovered."

CASE 4.—Miss H., aged 32, sent to me with a history of stomach symptoms extending over several years. She had had hematemesis in '92 and '96, since which time she had suffered from flatulency and pain after food. For two years epigastric pain constant but increased by food. A year ago vomited daily, then relief for a time, but for some months only milk could be retained. Epigastric tenderness was well marked and on distending the stomach with CO₂ it reached half an inch below the umbilicus and far over to the right of the middle line.

5.10.00. Posterior gastro-enterostomy performed, a bone bobbin being employed.

Recovery uninterrupted. Returned home within the month, taking solid food without any discomfort and gaining flesh.

On November 8th Dr. A. wrote: "I have seen Miss H. since her return and there is every reason to be pleased with her condition. She has lost all her pain and is taking food well. Allow me to thank you for her restoration to comparative health."

Report of weight February, 1901, 8 stone, 6 pounds, at time of operation 6 stone, 12 pounds.

CASE 5.—Mr. H., aged 52, began to suffer in 1897, from symptoms of ulcer of stomach which were relieved by restricted diet and general treatment, but in July 1899 the symptoms returned with great loss of flesh and strength. Well marked dilatation of the stomach was discovered and operative treatment advised.

Lavage and other treatment were carried out in London and in Scotland, but without material improvement.

When first seen by me there was visible peristalsis with well marked stomach splash and a tender spot under the right costal margin. Although tall, the patient only weighed 8 stone, 10 pounds, and he was extremely weak and palid.

12.10.00. Operation. Hour-glass stomach found, but the stricture was not extreme. Puckering on anterior wall of the stomach with well marked thickening. Free HCl discovered in the stomach contents. Posterior gastro-enterostomy performed. Good recovery.

March 4, 1901, patient wrote from Bournemouth, saying: "I am pleased to be able to tell you that I have had no return of my former complaint and that I eat, drink and sleep well. Have got back to my former weight."

CASE 6.—History. J. S., aged 45, residing at Batley, gave the history of two years' pain about an hour after food, with great loss of flesh. For nine months he had vomited every day or every second day, a large quantity of yeasty material, but no blood, though he was very anemic.

There were well-marked signs of dilatation, with tenderness over the pylorus. Operation 12.6.00. On opening the abdomen the pylorus was much thickened and adherent, forming a tumor, and through the centre of the mass a No. 10 catheter only could be passed, over a roughened, ulcerated surface. A posterior gastro-enterostomy was performed.

After History.—An uninterrupted recovery followed. Food was begun the second day, and solids could be taken in the second week without pain. He rapidly gained flesh and strength, and is now well. The following case illustrates the value of gastro-enterostomy in acute hematemesis.

Chronic Ulcers; Hematemesis; Gastro-enterostomy.

Mr. F., a farmer residing in Essex, was sent to me by Dr. A. J. T. White, on the 26th of March, and he kindly furnished the following history.

"I first saw Mr. F. 5 years ago. He had then occasional pain in the epigastrium, with much flatulence and at times vomiting. This kept on at intervals more or less for three years. 18 months ago Dr. G. saw him with me. At that time instead of his former weight of 16 stones, he only turned the scale at 12 stones. He then improved gradually for about three months and gained about a stone in weight. Six months later or about a year ago, he, while out driving, had some abdominal pain and vomited considerable quantities of blood. He continued being sick and suffering for some time with slight hematemesis and melena, but again improved. About 3 or 4 months ago, he got worse, and has been vomiting and suffering considerable pain on and off ever since. I have very little

doubt but that this original trouble was gastric ulcer, but my fear now is lest malignant ulceration should have supervened and some time ago I asked him to see you. He could not go then as he had various business matters to set right, but now is willing. He is a man of iron will and constitution though terribly pulled down." On Mr. F.'s arrival in Leeds he went direct to a surgical home. His weight then being 10 stone. He was then suffering severe pain but was able to take a little milk, which was in fact the only form of food he had been able to digest for a long time. Within a few hours he was seized with violent hematemesis and vomited 5 pints of clots and dark fluid mixed with mucus. Rectal feeding was at once adopted and an ice-bag applied to the epigastrium. The next day much coffee-ground material was vomited and on the third day the bleeding ceased. An operation, which was clearly demanded, was arranged for March 22nd, but on the night of the 21st he again vomited two pewters full of pure dark blood which clotted soon after being vomited. The stomach was quite empty of food, as after the night of his admission feeding had been entirely rectal. He was now extremely weak, but as the vomiting and bleeding were continuing Dr. White agreed with me that it would be better not to postpone operation, for he was rapidly losing ground and clearly could not stand a greater loss. An hour before operation he vomited blood freely again. On the morning of March 22d, on opening the abdomen, the lesser curvature of the stomach was found to be much indurated, forming a tumor. There was also much puckering of the surface of the stomach and the glands in the greater and lesser omentum were enlarged but discrete. A posterior gastro-enterostomy was performed, a bone bobbin being used. In order to guard against shock he was enveloped in cotton wool, had 10 minims of liquid strychniae (B. P.), given subcutaneously before operation and had a pint of saline fluid with an ounce of brandy given into the bowel. Immediately after operation, which was finished within the half hour, nearly a pint of saline fluid was injected into the subcutaneous tissues of the axilla and another pint together with an ounce of brandy administered per rectum. During the day three injections of 5 minims of liquid strychniae were given and the rectal enemata were repeated.

Very little shock was felt and the after progress was uninterrupted. The bowels were moved on the third day and the wound was dressed and found healed on the 10th. No more blood was parted with and stomach feeding was begun four days after operation. By the end of the week he was taking as much as 5 pints of fluid nourishment in the 24 hours. He said he had never had any pain since the operation and was feeling better than he had done for a long time. He had lost all the acid eructations, the constant burning at the epigastrium and the flatulency. He returned home within the month very well and as showing the state of his digestion he had gained 4 pounds in the week before he left the surgical home.

Pyloroplasty as a curative measure in this class of cases has certain very definite limitations, but where it is feasible it is a method of great utility which can be performed rapidly and with very little exposure of viscera. Pyloroplasty, if the pylorus be stenosed, free from extensive adhesions, easily drawn forward and not actively ulcerating, is a simple and short operation, and in quite a number of cases of both gastric and pyloric ulcer I have found it to answer well. It must not be relied on, however, where active ulceration of the pylorus itself is found, unless at the same time the ulcer be completely excised; otherwise cicatricial contraction will follow. It acts in the same way as does gastro-enterostomy, by affording a free exit to the stomach contents and thus securing physiological rest to the stomach.

The histories to be related exemplify the complete success which attended the operation in appropriate cases and also the disappointment which followed its employment in one of the earlier examples, which, owing to experience, was not properly selected.

Profs. Carle and Fantino (*loc. cit.*) compare the

operation of gastro-enterostomy and pyloroplasty. Out of fourteen cases in which the latter operation was performed only one died.

The results of pyloroplasty, as regards function, have been little noticed in literature. To the author's fourteen cases, three may be added where the operation was by tearing, but the results were the same. In all the seventeen cases the results were excellent, in thirteen of them perfect and permanent, as it is now from three to seven years since operation. In these the condition of the secretions and of the peristaltic power of the stomach was the same as after gastro-enterostomy for non-malignant stenosis. Diminution in size of the stomach was not so marked as would be expected in the presence of such remarkable recovery of the general health and of the stomach's power to empty itself. In all cases, with one exception, the gastric capacity was more or less diminished, but in no case did it become normal in size.

A few cases must be excepted where operation was performed for hyperacidity with gastric atony. In these, four or five months after operation, there was delayed evacuation of the stomach and a feeling of weight. Although the general improvement was considerable, yet the authors were persuaded that a posterior gastro-enterostomy would have given better results. In one of the cases a subsequent gastro-enterostomy gave a perfect recovery.

In cases in which there was hyperacidity before the operation, there was a rapid return to the normal, but *not to below* normal, as was found after gastro-enterostomy. The authors believe that the rapid and great diminution in hydrochloric acid after the latter operation is due to the very rapid evacuation of the stomach after a meal, and do not deny the possible influence of a regurgitation of bile into the stomach. Both these conditions are absent after pyloroplasty, hence the difference in secretion.

In cases of hypo- and anacidity, operation produced no change in this particular, and yet health was restored. The results of pyloroplasty may be summarized:

(1) Regurgitation of bile into the stomach is prevented.

(2) Secretion of hydrochloric acid, when it has been excessive, becomes normal.

(3) If the secretion of hydrochloric acid has been diminished or absent before operation, it remains "in statu quo" after operation.

(4) If there has been primary gastric atony, peristalsis is but little improved.

(5) This function improves rapidly or reaches perfection if the muscular contractility has been normal or increased, and when the obstruction was due to fibrous stenosis or pyloric spasm.

(6) In all such cases evacuation of the stomach is accomplished in its physiological period. Only in rare cases, and these only in the first months, after operation, may it be delayed.

(7) The capacity of the stomach always decreases, but rarely becomes as small as normal.

(8) The pylorus recovers tone.

Points of difference between the results of pyloroplasty and gastro-enterostomy are:

(1) The absence of regurgitation of bile, and hence the absence of any possible biliary influence on the gastric secretions.

(2) The evacuation of the stomach is not accelerated, hence the difficulty the stomach has in reaching its normal size.

(3) The slight or negative result obtained by pyloroplasty in obstruction from primary gastric atony compared with the positive results from posterior gastro-enterostomy.

Pyloroplasty is too dangerous in cases where there is extensive induration of the tissues, much peripyloritis and adhesions to liver, gall-bladder, colon, etc., and in cases of duodenal stenosis. It is indicated in cases of spasmodic stenosis, and in slight annular stenosis from ulceration accompanied by muscular hypertrophy.

Statistics. In the Hunterian Lectures I collected 318 cases of pyloroplasty from all sources, of which 269 recovered, which equals a mortality of 15.4%; this included 14 cases of the lecturers, of which 12 recovered a mortality of 14.2%. As in the earlier operations, many were performed on cases that would be now treated by gastro-enterostomy, the mortality in properly selected cases should not exceed 5% at the outside estimate, and of the 12 cases I have operated on since 1897, there is no fatality to record.

CASE 1.—9.3.95. Mrs. W., aged 29. "Spasms" for 10 years, but pain more on left side. Attacks two or three times a week, start without apparent reason, last an hour or two, but may persist 24 hours, relieved by vomiting. Severe cramps in legs, loss of 2 stones in weight; no jaundice, marked constipation. Rigid right rectus, no rigidity but tenderness to left. Dilatation of stomach well marked, 22.11.95. Relief under treatment followed by relapse, now vomiting daily. Weight, 9st. Operation. Adhesions of pylorus separated. Active ulceration at pylorus and tight stricture. Pyloroplasty (Bone Bobbin). 24.7.96. Weight 9st. 5 pounds, very much better. Relapse in '98, possibly from recurrence of ulceration. I then performed gastro-enterostomy. Quite well in 1900, and former weight fully regained.

CASE 2.—13.1.97. Mr. M. B., aged 52. Ulcer of pylorus with stricture. Pyloroplasty. Bad health for 20 years with dyspepsia worse since enteric fever 9 years ago. Last 2 years much worse, pain, sickness and vomiting 2 to 3 hours after meals relieved by vomiting of large amounts. Never vomited blood. Loss of flesh. Weight 9st. 3 lbs. Emaciation, dilatation of stomach. No tumor. Operation. Stricture of Pylorus. Pyloroplasty (Bone bobbin used). 19.9.98. Dr. W. writes: "For some time little improvement, stomach now works well. Looks better than I have ever seen him." Well February, 1901. Had gained normal weight.

CASE 3.—Mrs. W., aged 46. Stricture with active ulceration at pylorus. Pyloroplasty. Gastralgia for several years, relieved by food. In November, 1894, vomited dark fluid, since then frequent vomiting, longest interval 2 or 3 weeks. Pain in stomach accompanied by hard lump and often followed by vomiting. Great loss of flesh and strength. Operation. Pyloroplasty for contraction and thickening of pylorus, passage only admitted No. 2 catheter. Good recovery. Well 1899. Considerable gain in weight.

CASE 4.—24.5.97.—Mr. H., aged 39. Letter dated May 14, 1897, to say: "During the last 18 months I have suffered much pain, which has caused me to be bedfast for two, three or four weeks at a time, and it has required another month or more for me to gain strength enough to move about." Eighteen months ago epigastric pain several hours after food, relieved by vomiting. Since then health never good. 3½ months ago similar attack, very severe with collapse. Vomit contained blood. Fourteen days ago another severe attack normal weight 10 stones 10 pounds, now 9 stone 3½ pounds. Stomach "weak" since childhood. Marked dilatation. No tumor. Operation. Deep ulcer at pylorus. Extreme stricture barely admitting ordinary dilator. Pyloroplasty. (Bone bobbin used). Complete recovery from operation and rapidly regained normal weight. Letter dated 10.2.1901 says: "I am well."

you would like to know that I am able to attend business as usual and have done so without interruption since July 19th, 1897.

CASE 5.—12.7.97. Mrs. W., aged 46. Said to have had ulcer of stomach 20 years ago. Since then subject to attacks of pain, loss of flesh, and vomiting. Pain, for 3 or 4 months vomiting 3 times a day, lost a stone weight in that time. Leading life of an invalid and for a long period under medical treatment without benefit. Dilatation of stomach, visible peristalsis, tenderness over stomach, especially at the pylorus. No tumor could be felt. Operation. Stomach much dilated, thickening at pylorus. Pyloroplasty. (Bone bobbin used). Good recovery.

8.1.98. Weighed 11 stone, a gain of over two stones.

CASE 6.—27.7.97. Mr. C., aged 23. Vomiting and loss of flesh for 2 years. Once was 10 stone, now is 7 stone in weight. Dieting and lavage give only temporary relief. Emaciation, pallor, dilatation of stomach. No tumor. Operation. Much contracted pylorus, great hypertrophy, the walls more than one-third of an inch thick. Pyloroplasty with bone bobbin. Good recovery. 23.12.97, weight 9 stone 13 pounds. Well.

CASE 7.—W. F., aged 52, had suffered from indigestion for two years. This, however, had not interfered much with his general health till the previous Christmas, when the indigestion was accompanied every second day by acute pain and vomiting, coming on about two hours after food. The vomited matter was in large quantity, offensive and sour, and at times coffee-ground in character. From this time the patient became extremely weak and pale, and rapidly lost flesh to the extent of 1½ stone in five weeks. He had pain on pressure over the pylorus, but no distinct tumor was felt. There was marked dilatation of the stomach, and during the attacks of pain it could be felt to harden under the hand.

On April 8th, 1895, the abdomen was opened by an incision in the middle line above the umbilicus, exposing the pylorus, which formed a distinct tumour adherent to and under cover of the liver, and which, after being freed from adhesions to surrounding structures, was found to be tightly strictured, so as only to admit the passage of a No. 12 catheter; the mucous membrane being extensively ulcerated, and the walls thick and almost cartilaginous. The stricture was incised longitudinally and sutured transversely over a bone bobbin by a double row of sutures. The stomach was much dilated and atonic. Though the pyloric tumor gave rise at the moment to a suspicion of cancer, there was no evidence of growth, and the glands were not affected.

October 30, 1896, he called to report himself, looking robust and well. He had gained 3 stones in weight since his operation.

Gastro-plasty is an operation that I have successfully employed in a number of case of chronic ulcer leading to hour-glass stomach. It consists in making a longitudinal incision through the strictured part of the stomach and bringing the edges of the wound together transversely, thus obliterating the stricture.

A convenient method of performing the operation is by the use of a large decalcified bone bobbin, as described in the cases appended. If the strictured part of the stomach be actively ulcerating, the ulcer must be excised at the same time, otherwise subsequent contraction may occur; or possibly the ulcer, already chronic, may persist and lead to a continuance of the symptoms; in such a case, if excision be impracticable, gastro-enterostomy must be performed, or if the pylorus be free from disease the operation of *gastro-gastrostomy* may be done in order to short circuit the constriction.

I have operated on 13 cases of hour-glass stomach due to chronic ulcer, with 12 recoveries.

The following are good examples:

CASE 1.—M. B., aged 29, gave a four years' history of ulceration of the stomach, with vomiting of blood on one

occasion, and the presence of a melaena several times. As the pain was always easier when the patient was lying on the back, an ulcer on the anterior surface of the stomach was diagnosed.

This was confirmed at the operation, as the anterior wall of the stomach was so puckered that the cavity was divided into two, which were connected by a narrow channel, which was laid open by a free longitudinal incision, in which was laid a large bone bobbin, the wound being then brought together transversely over it, thus leaving a channel of nearly two inches between the two cavities.

The patient went home within the month, and has completely recovered her health and strength.

CASE 2.—Mr. D. H., aged 44, admitted with well-marked dilatation of the stomach, and a history of twenty years' stric trouble.

The constriction in this case was two and a half inches from the pylorus, the cavity between the stricture and the pylorus being very much smaller than the proximal one. The treatment was by gastroplasty over a large bone

Recovery was delayed by an attack of pleurisy, but the patient is now quite well, and has gained rapidly in weight.

CASE 3.—Double hour-glass contraction of stomach. Gastroplasty and Gastrolysis.

Miss M. P., aged 20. There had been attacks of pain and vomiting for 15 years. The pain began at the left side and passed to the epigastrium and through to the left subscapular region. There had been severe hematemesis 10 years before. Occasionally, both before and since the vomit had been streaked with blood, which was sometimes "coffee-ground," but it had contained no large quantity of blood for eight years. The patient vomited large quantities at times and had lost flesh steadily for the last five years. There were dilatation of the stomach, and peristalsis. No tumor could be felt but the pylorus was felt to harden from time to time.

Operation. 6.6.99, at a surgical home in Leeds. Double hour-glass contraction discovered. One-third of the distance from the cardiac extremity adhesions caused a marked diminution of calibre, and two inches from the pylorus a contraction only admitting the tip of the little finger was found. The adhesions were divided and gastroplasty was performed, the wound being sutured over a large bone bobbin.

After history. The patient made an uninterrupted recovery, and in two months she had gained 2 stone in weight.

CASE 4.—Extreme hour-glass contraction. Gastro-plasty.

Miss H. D., aged 48. The patient had had constant indigestion and flatulence for 20 years with a feeling of pulsation and tenderness at the epigastrium. There had been free hematemesis two years before and vomiting occasionally since, but lately the patient had ceased to take much solid food. She had noticed slime and blood in the motions, possibly due to constipation, which was extreme. There had been great loss of flesh. No tumor was present, but there was tenderness in the epigastrium and a well-marked splash on succussion.

Operation. 28.7.99. Extreme contraction one-third way from pylorus, just admitted tip of little finger. Gastroplasty was performed, a large bone bobbin being used.

After history. The patient made a good recovery from the operation and the digestion was relieved. There was an increase in weight of about a stone and improvement in the general health, but the stomach remained dilated and she continued anemic and weak. This was at first thought to be due to bleeding from piles, but after they had been ligatured the weakness still continued, and although there was no vomiting, flatulency and discomfort after meals with loss of appetite led to a suspicion of recurrence of disease in the stomach, which on being distended with CO₂ reached 3 inches below the umbilicus and on being washed out after a test meal, showed impaired motility.

January 24, 1901. The abdomen was opened again through a median incision above the umbilicus, when marked dilatation of the stomach was seen with contraction and some thickening over the pylorus, but where the hour-glass contraction had been operated on 18 months previously, it was interesting to note that neither scarring

possible to tell by the naked eye appearances that anything had been done.

A posterior gastro-enterostomy was performed, a bone bobbin being employed. Recovery was uninterrupted, and before the patient left the home at the end of the month she was taking ordinary food with relish and without any discomfort. She had then gained several pounds in weight.

Adhesions of the stomach to adjoining organs are so common in chronic stomach ulceration that *gastrolysis*, or the detaching or otherwise treating bands and short adhesions to adjoining viscera or to the abdominal wall, is performed in by far the greater number of cases. Such adhesions are frequently only the remnants of ulcers that have healed; at other times they have been left by perforation of the stomach wall by an ulcer, from the direful consequences of which they have saved the patient. In many cases they give rise to symptoms resembling ulcer, though the adhesions may be due to causes, such as gall-stones, outside the stomach itself; in such cases the operation of gastrolysis may be entirely curative. I have performed gastrolysis in 56 cases, all of which have recovered.

The following case is given as an example:

Gastrolysis for adhesions caused by chronic gastric ulcer.

Miss M. B., aged 42. Twenty-two years ago had symptoms of ulcer in the stomach, since then has suffered from vomiting attacks every week or two, and from pain after food. During the last 3 years symptoms were more marked. Under medical treatment, with rest in bed, no improvement. Vomit large in quantity and fermenting, sometimes containing blood. Loss of weight to the extent of three stones. Great tenderness over stomach, especially to the left. Stomach dilated, reaching below umbilicus and well over to the right.

Operation. On anterior surface of stomach scar of an old ulcer is visible. Lesser curvature of stomach closely adherent to the liver. Pyloric extremity and first part of duodenum attached to gall-bladder and cystic duct. Adhesions separated and omentum interposed between pylorus and gall-bladder.

After-history. Perfect recovery. March 7, 1900, can eat anything without discomfort and is rapidly putting on flesh. Has gained 20 pounds since her operation. March, 1901, quite well; had gained over two stones in weight. Many other examples of gastrolysis might be given where the benefits derived from operation have been quite as great.

Pylorodiosis, by which name is understood the operation of stretching the pyloric sphincter, either by means of the fingers invaginating the stomach wall, when it is known as "Hahn's operation," or by digital or instrumental stretching after having made an opening into the stomach, when it is known as "Loreta's operation," is a method of little practical value in the treatment of ulcer, and in some of the cases where I performed the operation, though the immediate results were good, relapses subsequently occurred. If performed by invagination without opening the stomach cavity, it is an operation unattended by risk. It may possibly be of service in simple spasm of the pylorus, but I have not much faith in its effects being lasting.

Did the time permit of it, it would be easy to give from my own experience examples of operations for all the complications of gastric ulcer that I have mentioned, and as many of the cases are of great individual interest, I think they would have proved interesting to my audience, but it is quite impossible to do more than refer to them unless I am to occupy

the whole of the afternoon, and this I have neither the desire nor the intention of doing.

I will, however, mention the results of my experience in operations for simple diseases of the stomach out of over 200 operations that I have performed.

In 56 cases I have performed gastrolysis for the separation of adhesions which were producing disabling conditions, all the patients recovering. In 13 cases I have operated for hour-glass stomach due to ulcer, 12 of the patients recovering and being now well.

In 6 cases I have operated for hematemesis, with five recoveries; in 4 cases for fistula, due to chronic ulcer, all the patients recovering.

Of the 18 cases in which I have performed pyloroplasty, 16 have recovered, the two deaths being in the earlier cases, one being due to perforation in the second week after operation.

Of the posterior gastro-enterostomies, previously referred to for simple diseases of the stomach, in 40 cases there were two deaths, both due to accidental causes, one being pneumonia in a phthisical patient.

Of the anterior gastro-enterostomies, including cases operated on 10 years ago, in 19 cases there were 4 deaths, one from an accident at the time of separation of a Murphy's button, one from shock in a patient very exhausted at the time of operation (Senn's plates being used), one from perforation of an ulcer on the 12th day, when apparently convalescent, and one from peritonitis extending from the abdominal wound.

Of the 2 gastroplications, both recovered.

Of the three cases of pylorodiosis, all recovered.

In 8 operations for perforating gastric ulcer there were two deaths directly following on operation in cases treated when peritonitis was general.

Of the 6 cases in which I directly excised a gastric ulcer or ulcers after opening the stomach by gastrotomy, all recovered.

Of one case of gastrotomy for the removal of foreign bodies and one for perforating wound of abdomen with hematemesis, both patients recovered.

It will be seen that out of 177 operations for simple diseases of the stomach, including perforation and hemorrhage, 165 patients recovered, or 93.2 per cent.

Description of the method of employing the decalcified bone button.—In the course of my paper reference has been made to a method I have been systematically pursuing since 1891, not only in stomach operations, but in nearly all the operations which involved the making of an anastomotic opening between the hollow viscera. I mean the method of suture over a decalcified bone bobbin.

I have adopted it in a very large number of cases and in a great variety of operations, and as a result of this extensive experience I am more than ever convinced that it is a reliable procedure which I can thoroughly recommend to others. It is more easily demonstrated than described, and at the end of this discussion or at such other time as you, sir, may think it desirable, I shall be pleased to show the method either on the cadaver or on a model. It is really very simple, and only involves two continuous sutures, one of chromicised catgut to unite the

mucous margins of the two openings and one of celluloid thread to unite the serous surfaces about a quarter of an inch away from the new opening. Pagenstecher's thread or spun celluloid has replaced silk in my practice, it being stronger, easily sterilized by boiling, and less absorbent.

The bobbin, which is made for me by Messrs. Down Bros., of London, in various sizes, from the small one required for cholecystenterostomy or for the union of the small viscera of children, to the large one employed for gastropasty or for the end to end union of large intestine in the adult, is nothing more than a cylinder of decalcified bone with raised ends, which is placed in the new anastomotic opening, around which the sutures are applied.

The advantages claimed for the method are:

1. That it secures the opening, being of the exact size intended, and that there is no possibility of the passage being made too small by the drawing up of the sutures before the knots are tightened.
2. That it secures an immediately patent channel between the two anastomosed viscera.
3. That the bobbin protects for from 24 to 48 hours the new line of union from pressure and from the irritation of the visceral contents.
4. That it facilitates the application of the sutures and so adds to the expedition of union by sutures.
5. That no foreign material is left in the alimentary canal, which may irritate or cause subsequent trouble, for the bobbin rapidly dissolves in the alimentary juices.
6. That the method has now been proved by ample experience to be rapid, easy, efficient and safe.

For stomach operations it is used in gastro-enterostomy, in pyloroplasty, in gastropasty, and in pylorotomy or partial gastrectomy, and in the latter operation it is unnecessary to use more than two continuous sutures for the whole operation.

In adopting the method, it is convenient to begin with the serous suture, which is applied around the posterior half of the circle. The needle still threaded is then laid aside till the final stage; the openings into the viscera are then made, and any redundant mucous membrane cut away; the mucous suture is now applied uniting the posterior half of the circle; the bone bobbin is now inserted and the mucous suture continued around the anterior half circle until it reaches the point where the mucous stitch was begun and where the loose end will be found; these two ends are then tied firmly: the serous suture previously laid aside is now picked up and continued around the anterior half circle until the loose end of the celluloid thread is reached, when the two ends are tied firmly.

The two hollow viscera are now united by a hollow cylinder of decalcified bone surrounded by two continuous threads, one uniting the mucous margins and one the serous surfaces, about 1-4 or 1-3 of an inch away from the anastomotic opening.

LATE RESULTS OF THE TREATMENT OF INOPERABLE SARCOMA WITH THE MIXED TOXINS OF ERYSIPELAS AND BACILLUS PRODIGIOSUS.

By WILLIAM B. COLEY, M. D.,

of New York.

Attending Surgeon to the General Memorial Hospital, Assistant Surgeon to the Hospital for Ruptures and Uppercuts.

In May, 1894, I was highly honored by an invitation of the American Surgical Association to read my first paper upon the treatment of inoperable malignant growths with the mixed toxins of erysipelas and bacillus prodigiosus. The results up to that time, though remarkable, covered a comparatively small number of cases, and had not stood the test of time. Yet, the words of kindly encouragement then received from the members of the American Surgical Association did much to stimulate my enthusiasm and helped me to persevere during the period of doubt and discouragement that necessarily attend the introduction of any new method of treatment of malignant tumors, and especially the treatment of malignant tumors already pronounced inoperable and hopeless by competent authorities.

Seven years have passed since the reading of the paper referred to, and just a decade since the beginning of the experiments of Dr. Bull and myself with the living cultures of erysipelas in inoperable sarcoma, and the practical question may well be asked by the profession: "Has the toxin method fulfilled any of the early hopes and claims? In other words, just what—in brief—is its proper place in the therapeutics of malignant tumors?"

This question is certainly a fair one, and I shall attempt to answer it in the briefest possible way and do so after the manner of the judge rather than the advocate. The results of this method during the last three years have given me no reason to change the conclusions expressed in my earlier papers, and I have nothing new to add in the way of improvement in technique or in preparing the toxins. While the results are far better in spindle-celled sarcoma than in any other form, there has been a sufficient number of round-celled sarcomas successfully treated to make it advisable to give every patient with inoperable sarcoma the benefit of a brief trial. If no improvement has occurred at the end of 3 or 4 weeks of daily injections, the treatment is not likely to be successful. If improvement does occur, the treatment should be kept up, either until the tumor has entirely disappeared or until it has become evident that the injections have lost their inhibitory influence. The toxins may be given for long periods in moderate doses without harm to the patient. The risks of the treatment are practically nil, if proper precautions are observed. In upward of two hundred cases I have had but two deaths, both of which occurred more than five years ago. It should be remembered that the method is advised only in inoperable tumors, and practically only in sarcoma; in other words, in the entirely hopeless cases. As above indicated, the percentage of probable cures depends largely upon the type of cell, varying from perhaps four or five per cent. in the round-celled, to nearly fifty in the spindle-celled variety. Up to

the present time I have had no success with the toxins in the treatment of melanotic sarcoma, although I have tried them in about a dozen cases. In some of these cases the disease was held in check for some time, but after a longer or shorter period the inhibitory action of the toxins was in some way lost. Lympho-sarcomas of the neck form another class that, up to the present time, justifies a prognosis almost as bad as that in melanotic growths. Although I have treated a large number of such cases most carefully and for long periods of time, I have not as yet had a single permanent success. These cases are nearly all of very rapid growth, and very highly malignant. It should be borne in mind that these lympho-sarcomas of the neck are also practically hopeless from the start, from an operative point of view. Butlin states that he has been unable to find a record of a single case in which a cure has resulted from operation. In spite of these discouraging results in melanotic sarcomas and lympho-sarcomas of the neck, the remarkable inhibitory action of the toxins that I have observed in certain tumors of these varieties, justifies us in advising a thorough trial of the treatment in all such cases, unless the disease is very far advanced or has already become generalized. After generalization has occurred—whatever be the variety of sarcoma—I doubt that any permanent result can ever be obtained by the toxins.

In August, 1898 (*Journal of the Am. Med. Ass'n*), I published my results in 140 cases of inoperable sarcoma treated with the mixed toxins. In 24 of these the tumor completely or partly disappeared. Eighty-four of this series were round-celled sarcoma; 21 spindle-celled; 9 melanotic sarcoma; 2 chondrosarcoma; 12 were sarcoma (diagnosis confirmed by the microscope, but type of cell not stated); 6 were inoperable sarcoma resting on clinical diagnosis combined with a history of repeated recurrence in most cases.

In 40, or slightly less than half of the round-celled cases, there was more or less improvement, as shown by decrease in size and cessation of growth. In only three of these was the treatment successful.

Of the 21 cases of spindle-celled sarcoma, ten disappeared entirely, and all the remainder showed marked improvement.

In melanotic sarcoma, as I have stated, I have had no successes. It should be noted, however, that Dr. George R. Fowler, of Brooklyn, has reported one case of melanotic sarcoma of the tonsil and fauces, which entirely disappeared under the use of the mixed toxins. The patient remained well for two years, when a local recurrence followed and proved fatal.

In addition to these personal results, the paper contained a summary of results in 35 cases successfully treated by other surgeons employing the same method. Of these 35 cases, 10 were round-celled; 10 spindle-celled; in 5 the diagnosis was clinical only; in 5 there was, in addition to the clinical signs of sarcoma, a history of recurrence after operation; in 4 the diagnosis of sarcoma was confirmed by microscopical examination, but the type not stated; 1 was an endothelio-sarcoma.

Of these 35 cases, 20 disappeared completely; 2

others decreased so much that only a small node was left, which was easily excised. One of the latter cases was well three years, and the other one year at the time of the report.

Of the 35 cases referred to, 14 were well over two years, and 6 cases over three years.

At the time of my report (Aug., 1898), 8 of my cases had remained well from 3 to 6 years. I have made a very great effort to trace the after-histories of these patients, with the following results:

CASE 1.—Recurrent, inoperable spindle-celled sarcoma of the neck and tonsil, treated with the injections of the living cultures of erysipelas, in May, 1891, for four months, during which time a severe attack of erysipelas occurred. The tumors nearly disappeared and the patient recovered perfect general health. He remained well for eight years, at which time the malignancy reappeared and proved fatal during the following year.

CASE 2.—Recurrent mixed-celled sarcoma (round, oval and spindle) of the back and groin. The patient was first treated in April, 1892, with the living bouillon cultures of erysipelas. The tumor entirely disappeared. It recurred two months later and finally disappeared under the mixed toxins. During the treatment the patient had four attacks of erysipelas, artificially produced. He remained well for 3½ years, then had an intra-abdominal recurrence, of which he died in about six months.

CASE 3.—Inoperable spindle-celled sarcoma of the abdominal wall and pelvis, 7x5 inches in diameter. The tumor entirely disappeared under four months' treatment with the mixed filtered toxins. The boy was in perfect health when last seen, between 7½ to 8 years after treatment. The diagnosis was confirmed by Dr. H. T. Brooks, pathologist at the Post-Graduate Hospital.

CASE 4.—Large, inoperable sarcoma of the abdominal wall. The patient, female, aged 28 years, had an exploratory laparotomy performed in August, 1893, at the Massachusetts General Hospital, by Dr. Maurice H. Richardson. Such a large portion of the abdominal wall was found involved, that removal was considered impossible. A portion of the growth was excised for microscopical examination, and pronounced spindle-celled sarcoma by Dr. W. F. Whitney, pathologist of the hospital. The treatment with the mixed toxins was begun in October, 1893, and was continued for about four months, with the result that the tumor entirely disappeared. The patient remains in perfect health at the present time, nearly eight years after treatment.

CASE 5.—Spindle-celled sarcoma of the leg and popliteal space, three times recurrent. The tumor disappeared under the toxins, but recurred 1½ years later. Amputation below the trochanter was performed, but a growth soon appeared in the gluteal region. This grew in size very rapidly and was quite inoperable. The toxins were administered for a number of weeks; the greater portion of it was removed under ether. The toxins were continued after the operation, with intervals of rest, for nearly a year. The remaining portion of the tumor disappeared and the patient is at present—more than four years afterwards—in perfect health, without any sign of return.

CASE 6.—Spindle-celled sarcoma of the scapular region involving the soft parts of the left half of the thoracic wall. The patient, a girl of 16, was admitted to the N. Y. Cancer Hospital, June 20, 1894. The tumor had started in the left scapular region four months before, and had grown very rapidly, until it measured 13 inches vertically behind, 7 inches in front. The growth seemed adherent to the scapula and the ribs; it was about two inches in thickness in its most protuberant part. A portion from this region was removed, under cocaine, for microscopical examination, and the diagnosis of spindle-celled sarcoma was made by Dr. H. T. Brooks, pathologist of the Post-Graduate Hospital. The tumor entirely disappeared by absorption, without breaking down, under about three months' treatment. The after-history of this patient is of great interest, and will very shortly be published in detail by Dr. Buxton and myself. She remained well for six years and then developed a papillary growth in the region of the right scapular and right pectoral muscles. A portion of the tumor, removed from the pectoral region in October, 1900, seemed histologically to be fibrous tissue, infiltrating the pectoral muscle. The diag-

nosis of progressive, muscular fibrosis was made by Dr. Buxton. Shortly afterward, a piece of new bone, about 2 inches long and $\frac{1}{2}$ inch in diameter, was removed from the pectoral muscle. A little later, a new bony formation occurred in the region of the sterno-mastoid muscle and was removed under ether. A portion of soft tissue was also removed from the scapular region, and microscopical examination showed the characteristic changes of myositis ossificans.

CASE 7.—Round-celled sarcoma involving omentum, colon and lobe of small intestine. The diagnosis was made by Dr. Willy Meyer, confirmed by exploratory laparotomy and microscopical examination of a portion removed, by Dr. F. Schwyzer, pathologist to the German Hospital. The toxins were begun in September, 1894, and continued for about four months. The tumor slowly disappeared in size and finally disappeared. A year later, several calculi were removed from the gall-bladder, with no evidence of a tumor to be found. The patient was in perfect health four years after treatment.

CASE 8.—Inoperable angiosarcoma of the breast, treated in spring, 1895, at the New York Cancer Hospital. The growth became sufficiently reduced in size to be easily removed. The patient was well when last seen, about six months later.

CASE 9.—Recurrent, spindle-celled sarcoma of the palm of the hand. The growth entirely disappeared under two months' treatment. The patient remained well for about 2½ years, when there was a local recurrence. This at first responded to the toxins, but later they evidently lost their control. Amputation of the arm was advised. The patient refused operation and chose the Christian Science treatment for a period of eight months, during which time the tumor increased from the size of a small walnut to that of a coconut, and extended nearly to the elbow. Amputation just below the shoulder joint was performed, but with no hope of doing more than removing the foul and sloughing mass, as evidence of generalization had already appeared. She died in 3 months.

CASE 10.—Recurrent, spindle-celled sarcoma of the thigh and groin, in a female, aged 48 years. The tumor was partially removed in March, 1896, at the New York Hospital, by Dr. Bull. A large mass remained in the inguinal region, and there was marked edema of the whole leg. The toxins were begun on May 30, 1896, and continued for about three months, at the end of which time the tumor had entirely disappeared and the left leg had become normal in size. The patient remained well for about a year, when she had a local recurrence. The toxins were again administered with temporary improvement, but later the disease returned and proved fatal in less than a year.

CASE 11.—Spindle-celled sarcoma of the iliac fossa, probably starting in the ilium. The patient, Mrs. D., aged 40 years, first noticed a growth in the right iliac region in the early part of 1895. This increased steadily in size, until October, 1895, exploratory laparotomy was performed by Dr. Johnston, of Boston. The tumor was about the size of a coconut, attached to the ilium as well as abdominal wall and was totally inoperable. It seemed to start from the crest of the ilium. The diagnosis of spindle-celled sarcoma was made by Dr. W. F. Whitney, of the Massachusetts General Hospital. The treatment with the mixed toxins was begun by Dr. Farrar Cobb, of Boston, in November, 1895. In a letter the doctor stated that, at the end of six weeks' treatment, the growth had entirely disappeared. In May, 1896, six months later, the patient came to me with a well-marked recurrence, extending from the crest of the ilium nearly to the level of the umbilicus and as far to the left as the median line. The toxins were again begun and continued with intervals of rest, for three months, when the patient was discharged from the hospital for a few months' rest. When she left, the tumor was less than one fifth of its original size. She was readmitted to the hospital in November. The tumor had increased considerably in size during the interval of rest, but under the treatment began to diminish rapidly. She left the hospital in June, 1897, after six months, when the tumor had markedly decreased in size and her general health was good. Owing to a change of address, I was unable to trace her and believed that she had probably died, until I received a letter in December, 1900, 3½ years after the cessation of the treatment, more than four years from the beginning, in which she stated that she had been

in good health and been supporting the family during the entire time. She has noticed no evidence of a return of the growth.

CASE 12.—Inoperable sarcoma of the sacrum. The patient, male, 38 years, had a rapidly growing tumor in the upper portion of the sacrum, which could be easily felt on rectal examination. His weight had fallen from 175 pounds to 134 pounds within three months. He had lancinating pains in the legs with marked lameness. The clinical diagnosis of sarcoma was made by Dr. Francis P. Kinnicutt and confirmed by physicians and surgeons who examined him at St. Luke's Hospital. No microscopical examination was made. The toxins were begun in May, 1895. The injections in this case were all made in the gluteal region, remote from the tumor. The prognosis given was extremely bad. However, the patient began improving immediately after the beginning of the treatment and the patient had gained 28 pounds in weight two months later; his lameness had entirely disappeared and six months later no trace of the tumor could be detected on rectal examination. The patient was in perfect health, weighing 175 pounds, when last seen, nearly four years after the treatment.

CASE 13.—Inoperable sarcoma of the iliac fossa. E. S., male, aged 14 years. A year and a half previously he had been dragged under a trolley car, causing contusions about the pelvis. In January, 1895, he began to feel pain in the right groin and a tumor soon developed in the right iliac fossa. Exploratory laparotomy by Dr. George R. Fowler, of Brooklyn, on March 7, 1897, showed a vascular tumor, filling up the whole right iliac fossa, extending upward three inches above the crest of the ilium and Poupart's ligament. The tumor was so vascular that Dr. Fowler did not think it wise to remove a portion for examination. He closed the wound and regarded the case as entirely hopeless. The condition continued to grow rapidly worse after the operation and on April 10, 1897, the mixed toxins were given as a last resort. The treatment was carried out under my direction by Dr. G. H. Davis, of Brooklyn, and continued for several months. The improvement was immediate and rapid. At the time it was begun, the patient was extremely emaciated, with marked cachexia and could not have weighed more than sixty pounds. Within the next three weeks he was walking about and had gained at least ten pounds in weight. Examination of the abdomen showed that the tumor had almost entirely disappeared. The injections were not made into the tumor, but into the gluteal region and upper thigh. A few months later he developed a fluctuating swelling over the ilium behind. The skin became broken, and a slight infection occurred, causing some temperature. I incised the swelling, evacuating several ounces of degenerated, broken down tissue. No bare bone was detected at any time. The curettings of the walls of the cavity were carefully examined and not the slightest evidence of tuberculous disease could be found, practically verifying the original diagnosis of sarcoma. Another, similar operation was performed on April 10, 1898. The boy has remained in good health up to the present time, four years later.

CASE 14.—Spindle-celled sarcoma of the abdominal wall. The patient, a girl of 18 years, was admitted to the New York Cancer Hospital, December 29, 1896, with a tumor in the lower part of the abdomen of several months' duration. Exploratory operation performed by Dr. Joseph Brettauer and Dr. George W. Jarmon. A large mass was found in the abdomen, both intra- and extra-peritoneal. It was regarded as entirely inoperable. A portion was removed and the diagnosis of spindle-celled sarcoma confirmed by Dr. Buxton, pathologist of the hospital. After thirty injections—the largest dose being 6 minims—of the filtered toxins, the tumor had entirely disappeared. Very little pain and discomfort resulted from the treatment, and but four chills occurred during the entire time. The patient was in perfect health, without recurrence, 1½ years later, when she returned to Germany.

CASE 15.—Spindle-celled sarcoma of the parotid gland. The patient, a man of 40, was carpenter by occupation. The tumor was first noticed early in 1897. It grew rapidly and in March, 1897 was removed by Dr. J. W. Wright, of Bridgeport, Conn. A second and a third operation were performed in April, but the growth was found too extensive for removal. The submaxillary glands of the same side were involved. In July, 1897, the patient was treated with the mixed toxins at the Bridgeport Hospital, for three

weeks, with little improvement. He was sent to me by Dr. Wright, August 10, 1897, for advice and treatment. Believing that perhaps the toxins had not been pushed to their full limit, I began with daily doses, increasing to the point of producing a chill and temperature of 103-104° nearly every day. The patient's excellent condition enabled him to withstand this severe treatment without loss of weight. He was up and about the ward the entire time. Some improvement was evident at the end of two weeks and although this was not great, it continued constant until the middle of October, when the disease had entirely disappeared. The patient was shown before the N. Y. Surgical Society in March, 1898, in perfect health. I received a letter from him, dated April 29, 1901, stating that he was still in good health, without recurrence, nearly four years after treatment.

CASE 16.—Three times recurrent mixed-celled (round and spindle celled) sarcoma of the parotid. Female, aged 34 years. The tumor had been removed three times by Dr. William T. Bull, and further operation was deemed inadvisable. Dr. Bull kindly referred the case to me for treatment with the toxins. The injections were begun in January, 1897, and continued for seven months in very small doses. The patient was extremely nervous. The tumor became much reduced in size and very movable, so that most of the tumor could be easily removed under ether anaesthesia. It would have been impossible to remove all of it without sacrificing the facial nerve. The toxins were continued after the operation for a considerable time, in very small doses, nearly sufficient to produce a chill. The patient is still well and free from recurrence, more than four years later.

CASE 17.—Twice recurrent round-celled sarcoma of the lower lip. The patient, a little girl, 5 years of age, daughter of a physician in Tacoma, was referred to me in February, 1897. The diagnosis of round-celled sarcoma was confirmed by the pathologists of the Cancer Hospital, Drs. Dunham and Buxton. In this case the mixed toxins were used for about 6 weeks, with the result that the growth entirely disappeared. The patient has remained well up to the present time, more than four years after the treatment.

CASE 18.—Eight times recurrent spindle-celled sarcoma of the chest wall, soft parts. The patient, male, himself a surgeon of prominence, had been operated upon eight times, for rapidly recurring spindle-celled sarcoma of the chest wall, soft parts. The intervals between operation and recurrence were becoming shorter and shorter, and the character of the growth more vascular and more malignant. The toxins were begun in November, 1894, and used in small doses for 3½ years with intervals of rest. The patient gained in weight under the treatment and continued to perform his daily duties. Two to three small nodules were removed during the treatment. He has had no injections now for nearly four years, and there has been no evidence of return.

CASE 19.—Inoperable sarcoma of the tibia. Male, aged 25. The patient was admitted to the General Memorial Hospital in February, 1899, with a recurrent tumor of the tibia, for which amputation had been advised. A portion of the growth removed had been examined by Dr. John Caven, Professor of Pathology at the University of Toronto, and pronounced spindle-celled sarcoma. In view of this report I believed it to be wise to give him the benefit of a short period of toxin treatment, before amputating. After about two months, the tumor had apparently disappeared and the injections were discontinued. The tumor disappeared partly by sloughing and the granulating area left behind became infected with erysipelas, there having been a case in the ward some months before. The patient had a very severe attack of erysipelas, extending over the whole leg and portion of the body, and after recovering from this he returned home. He remains in perfect health at the present time, and has continued his occupation as farmer.

CASE 20.—Very large recurrent sarcoma of gluteal region. Inoperable. The toxin were administered for two months in 1893. The tumor slowly decreased in size and after several months became very small and all evidence of malignancy disappeared. Five years later she was in good health. I then removed two hard, fibrous nodules from site of growth, and they proved to be pure fibrous tissue.

CASE 21.—Large chondrosarcoma of the ilium, which

disappeared under the treatment. The patient remained well for seven months, when a recurrence took place, which proved fatal in about a year's time.

CASE 22.—Fibro-angioma of the lip. Recurrent in operable was well when last heard of, over two years after treatment.

CASE 23.—Inoperable epithelioma of the chin, lower jaw and floor of mouth. The growth disappeared entirely under four months' treatment with the mixed toxins. The patient was well, without recurrence, when last seen, four years after treatment. The case was referred to me by Dr. Geo. R. Fowler, of Brooklyn, who regarded it as entirely inoperable.

CASE 24.—Spindle-celled sarcoma of the palm of the hand—three times recurrent—the toxins as a prophylactic measure immediately after the last operation. The patient is in good health 1½ years after operation. The patient, a boy aged six years, was operated upon by Dr. J. D. Bryant, in 1898, for acute traumatic sarcoma of the palm of the hand. A small operation was first performed, and later a more radical one, with removal of the ring and little fingers and their metacarpal bones. Recurrence quickly followed after each operation, and finally, in the fall of 1899, a sarcomatous tumor appeared in the axillary region. This was removed also by Dr. Bryant, and as soon as the wound had closed, the patient was referred to me for the toxin treatment. The injections were given in small doses, two or three times a week for about three months. The boy has remained in good health up to the present time, without recurrence.

The following cases of carcinoma are of special interest:

CASE 1.—Extensive recurrent carcinoma of the breast following amputation of both breasts for carcinoma. The toxins were used continuously for nearly four years. The patient is still alive, 4½ years after treatment.

This case is of great interest, as it shows that in certain conditions the toxins may be used to advantage even in carcinoma, especially as an aid to partial operation. The patient, Mrs. W. H., 56 years, was operated upon by Dr. Maurice H. Richardson, of Boston, for carcinoma of both breasts, October 8, 1895. Recurrence was first noticed in June, 1896, nine months after the primary operation. Dr. Richardson advised against further operation and referred the patient to me for opinion as to the propriety of using the toxins. I stated that I believed the treatment would prove of only temporary value, and might have no effect. I urged the removal of the carcinomatous area which, at this time was about 3 to 4 inches in size, infiltrating the skin, and as soon as the wound was healed to begin the toxins in the hope of delaying recurrence. Dr. Richardson removed the diseased area November 27, 1896. On January 1, before the wound had entirely healed, new nodules appeared in the outlying skin near the anterior axillary line. The toxins were begun on January 10, 1897, and continued in small daily doses for one month. The small nodules in the skin disappeared. After a short interval of rest her general health was much improved compared to what it was prior to the beginning of the treatment. She returned to her home in Massachusetts, and with occasional intervals of rest, the treatment was continued in moderate doses upwards of three years. On three or four occasions some minute localized skin infiltrations, not more than ¼ inch in diameter, were removed under cocaine. About a year ago, she developed ascites, and has been tapped by Dr. Richardson a number of times. No tumor has been felt in the abdomen, although it is quite possible that generalization of the disease has taken place. The fact remains that life has been unquestionably greatly prolonged by the continued use of small doses of the toxins in a most unpromising case of double recurrent carcinoma of the breast.

CASE 2.—Another case of rapidly growing recurrent carcinoma of the breast in a comparatively young woman, aged 40 years, with involvement of the axillary glands, was kept in good health with complete control of the disease from 2½ years by the administration of small doses of mixed toxins, two or three times a week.

While at the time of my report, in 1898, eight of my own cases had remained well from 3 to 6 years. I am now able to report sixteen cases that have remained well from 3 to 8½ years. Of these two recurred after 3 and 8 years respectively, one dying of

metastases in the abdomen; the second, after remaining well for 8 years, died of local recurrence.

The cases were all hopeless, inoperable cases, and the diagnosis was confirmed by the microscope with two exceptions. In these instances the history of the cases, with the clinical appearances, made the diagnosis of sarcoma unquestionable. The type of tumor in the fifteen cases that passed the three-year limit was as follows:

Spindle-celled sarcoma	9
Round-celled sarcoma	2
Mixed-celled sarcoma	2
Epithelioma	1
Sarcoma (clinical diagnosis only) ..	2

It is worthy of special note that two of the successful cases, now well $3\frac{3}{4}$ and $4\frac{1}{2}$ years, respectively, were sarcoma of the parotid gland. Butlin, in his last edition of "Operative Treatment of Malignant Tumors," states that: "Up to the present time there are very few instances of cure by operation of undoubtedly malignant disease of the parotid." In my two cases treated by the toxins, the diagnosis was not only confirmed by a competent pathologist, but, further, by a history of repeated recurrences after operation. Another case still is also worthy of special mention, inasmuch as it shows that the toxins may be taken for long periods of time without harm. The patient, a well-known physician, with eight times recurrent spindle-celled sarcoma of the soft parts of the chest (anteriorly) was treated with small doses of the mixed toxins with varying intervals of rest, for upwards of two years. The patient regained his usual health, and has now been perfectly well over six years from the beginning and four years since the cessation of the treatment. The tumors, while originally pure spindle-celled, were becoming more mixed with round cells and more vascular with each recurrence; in other words, the disease, as so often happens, was increasing in malignancy until the toxins were begun.

In addition to these sixteen cases that have passed the three-year limit, in eight others the tumors disappeared. One, a spindle-celled sarcoma of the abdominal wall, was well $1\frac{1}{2}$ years, when the patient returned to her home in Europe and was lost sight of. Another, an extensive round-celled sarcoma of the iliac fossa, was well one year and then lost sight of. A third, a spindle-celled, recurrent sarcoma of the leg, is now in perfect health, without recurrence, two and one-quarter years after treatment. A fourth, a twice recurrent, spindle-celled sarcoma of the palm of the hand, disappeared, and the patient remained well two and a half years, when the tumor recurred. Refusing amputation of the arm, she was under the care of a Christian scientist for eight months, during which time the tumor in the hand reached the size of a cocoanut and extended above the elbow. I then amputated the arm just below the shoulder joint, but she died of metastases three and a half months later. Though the patient was an especially intelligent girl, 22 years of age, while under the Christian science treatment, she watched a small tumor, the size of an English walnut, grow to the size of a cocoanut, and yet was made to believe it was actually getting smaller and improving. She also stated that she felt no pain. This is a good illustration of the utter impossibility of placing any value upon

personal statements of patients in regard to improvement or cure of malignant tumors by Christian science.

A fifth case, a chondro-sarcoma of the ilium, of large size, disappeared, and the patient, after remaining well for seven months, had a recurrence, which proved fatal in about a year's time. A sixth, a round-celled angio-sarcoma of the breast, was well six months later, when the patient was lost sight of. A seventh, a recurrent fibro-angioma of the lip, was well when last heard of, over two years after operation; and an eighth, a recurrent, spindle-celled sarcoma of the thigh, disappeared, but the patient, after remaining well for a year, had a recurrence locally and in the groin, which no longer yielded to the treatment.

In addition to these 24 personal cases, I would mention two other cases in which I directed the treatment, although it was carried out by another surgeon. One case (Johnson's), a large, spindle-celled sarcoma of the pharynx, entirely disappeared, and the patient was well more than six years later. The second (Storr's and Griswold's) inoperable sarcoma of the breast and axilla, disappeared under 78 injections of the mixed toxins, and is now well more than four years after treatment. The diagnosis in both of these cases was confirmed by microscopical examination, in the latter case by the highest authority in this country, Prof. William H. Welch, of Johns Hopkins University.

The results thus far, he stated, seem sufficient to warrant advising the treatment as a routine measure after all operations for primary sarcoma. While the treatment is not recommended in carcinomatous growths, it has been the experience of the writer that in many cases the toxins exert a marked inhibitory influence in carcinoma, although it is rarely curative. The only cases of carcinoma in which the toxins are likely to prove of much value, I think, are those in which they are used after primary or secondary operation, as a prophylaxis against recurrence. Up to the present time sufficient experience is lacking to justify one in making any definite statements as to how much may thus be accomplished.

The writer still believes that the action of the toxins upon malignant tumors can be explained only upon the theory that such tumors are the result of some infectious micro-organism, and this view is strongly supported by the recently expressed opinion of Czerny.

TRAUMA AS AN EXCITING CAUSE OF PARALYSIS AGITANS.*

By F. SAVARY PEARCE, M. D.,
of Philadelphia.

Read before the Section on Diseases of the Nervous System,
at the National Medical Association, Philadelphia, 1900.

The subject of *commotio cerebri* as an exciting cause of definite organic lesion of the neuron, was forcibly brought to the writer's attention in a case of Friedreich's disease terminating fatally, which was reported by Dr. John M. Swan and myself in the *Philadelphia Medical Journal* for May 26, 1900. In this case, definite exacerbation of the disease followed a "fall." Repeatedly following such injuries,

*Read by title before The Pan American Medical Congress, Havana.

conditions of tremor have been observed by the writer in cases not otherwise hysterical. The latter have recovered after the adoption of rest and nutritional measures. The subject, therefore, in the writer's experience, has lead him to suspect that disorganization of the glia and the neurons may have its starting point from undue concussion of the central nervous system. In this contribution, it is meant to bring more forcibly before the profession the fact that some of the degenerations of the nervous system are at least excited by concussion; and that trauma should be given place in etiology along with infectious diseases and other well-known causes. The above statement is re-enforced, too, by the knowledge of wide difference of opinion as to pathology in the so-called Traumatic Neuroses, as shown by the various papers read at the Symposium on this subject before the Section of Nervous and Mental Diseases of the American Medical Association, June 6, 1900. In this one gentleman took the ground that most of the tremors, rigidity of the back, and general nervous symptoms were largely of malingering, in some cases hysterical, and that there was no ground for suspecting the border line of organic spinal disease in any instance of this affection. The other speakers were more conservative in their statements, admitting a widespread functional disturbance to be excited by the injury, and Lloyd reported a case with an undoubted organic basis. Of course, we are barring all cases of actual fracture or displacement of the vertebra. The writer feels from the clinical evidence at hand, that many cases of traumatic neuroses are functional; and not a few, expressions of malnutrition with incipient secondary degeneration of the spinal axis, which, with rest and hyper-nutrition after months and even years, may ultimately recover, leaving the individual in good health. Other cases may go on to development of a system sclerosis.

But, as to our subject. Paralysis agitans is a disease found more frequently about mid-life, and whose pathology is indefinite; yet it is known that interstitial plaques of sclerosis, and hardening of the blood vessels do occur. Therefore, in the etiology of paralysis agitans, it could be that sudden concussion might excite connective tissue proliferation and an irritability of the motor neurons already in a condition of malnutrition; and I have no doubt that not a few cases of this disease date their onset of actual tremor from the time of a fall or other sudden concussion. I should say the older the case, the more likely is trauma to be a cause of the onset of paralysis agitans; and that even the senile tremor, so-called and so much simulating that of paralysis agitans, is often precipitated by some sudden cerebro-spinal concussion. Thus excitation of the afferent axons may cause an increase of irritation of motor neurons, the reflex message being carried back accentuated, producing tremor of the muscles and therefore of the extremity involved. The following case is illustrative of this source of tremor which obeys all rules of paralysis agitans, though aberrant in type, inasmuch as no other part of the body is involved excepting the woman's left arm.

CASE 1.—M. R., white, aged 65, fell from her porch, a distance of eight feet, producing quite a severe "shaking up," but with no marked concussion of the spine. She also

sustained by the accident, a fracture of the neck of the right humerus. This was on May first, 1898. The bone healed kindly after being set by her physician, but was followed by subacute arthro-neuritis involving the shoulder joint and brachial plexus. This I treated by galvanism, and later massage was administered. From this time on, the right shoulder troubled her, the range of motion remaining quite up to the normal, although there was slight stiffness in the movements of the arm. The patient remained in good health for a year, but about June 1st, 1900, she noted a fine tremor taking place in the left thumb and index finger when the arm was at rest. This would be made worse by over exertion or excitement of any sort, finally becoming at the end of a few months, a well marked and quite continuous dynamic tremor, always under control by intention. The hand is now distinctly held in the pill-rolling attitude but does not interfere with needle work. There is no nerve trunk tenderness or apparent weakness in this extremity. There is absolutely no tremor anywhere else in the body. There is a certain mask-like expression, however, but no festination is present.

I take it, the tremor in this case is due to the reflex transference of irritation from the right to the left motor neuron in the cervical region of the spinal cord, not an unknown but an unusual condition and is likened to the transference of trophic disturbance from one extremity to the opposite one by a severe burn as of the fingers. The tremor mentioned has been almost continuous since November, 1900. The facies of the patient as stated is somewhat expressionless, with head drooped slightly forward. These are the only other evidences of Parkinson's disease. On December 28, 1900, this patient was seen with me by Dr. S. Weir Mitchell who suggested the diagnosis given. There has been very little improvement with the prolonged use of galvanism and massage, and she is now taking increasing doses of Tr. Hyoscyamus. I cannot feel any doubt of this unusual origin of the tremor which is not due to a primary commotio-cerebri, per se, but to the secondary irritation of the spinal neurons from an afferent irritative impulse as indicated and transmitted to the opposite extremity as tremor.

The conclusions which seem to be the more definite as regards trauma as an exciting cause of paralysis agitans, are that the later the origin of the disease, is trauma more apt to have been the exciting cause; in any event, it is more apt to produce an aberrant type of the *malady*, especially when the insult to the nervous system has been primarily in the periphery of the body rather than of the central neurons.

Treatment would differ essentially in one particular of less widespread extent of the tremor, and therefore of less disturbance to the individual, although later the affection may become general. The downward course is, perhaps, less rapid than in so-called idiopathic cases.

Treatment would differ essentially in one particular to obtain better results of therapeutics. Nerve stretching seems to be a rational procedure in cases as here reported, where the tremor is localized, and especially where the reflex origin below the cerebrum seems to be pretty definitely the cause of the irritation of the motor neurons. I have advised this operation in the case in question, but as yet have not received the consent of the patient.

CASE II.—Pseudo-paralysis agitans following scoliosis of the cervical spine. M. S., aged 58, white woman in my wards at the Philadelphia Hospital, suffering from periods of mental excitation and fine tremor involving the right upper extremity; obeying the laws of a tremor of paralysis agitans. There is no other evidence of Parkinson's disease. The peculiarity of the case, therefore, is that at some remote period following this posterior cervical curvature of the spine, with more or less fixation, probably of rheumatic origin, we here have an instance most likely of irritation of the sensory motor roots of the nerves leading to the brachial plexus; and in this way, the localized tremor has perhaps been brought about. The rheumat

ic element in the case, too, is also shown by a slight arthritis recently occurring in the right knee joint. I am interested in the possible result upon the tremor, of treatment which we have directed to the rheumatic poisoning in this case and also, too, of probable relief of tremor we may get through prolonged head extension to the possible straightening of the curvature mentioned.

CASE III.—A third case of paralysis agitans in a man, due to trauma, is given me by my friend, Dr. Guy Hinsdale. A brief history is as follows: Male, white, age 45, fell upon his thumb some years ago, the digit bending under in extreme flexion. This was followed immediately by secondary ascending neuritis of the same arm that defied all treatment including nerve stretching which was done by Dr. H. A. Wharton. The case has gone on to a general symptomatology in all typical aspects of shaking palsy, and the man is now in the Home for Incurables, practically bed-ridden.

This latter case pretty positively proves the traumatic origin of a case that ultimately became general and typical of the disorder under discussion.

The two preceding cases, result of trauma or local irritation, I feel will progress in the same fashion unless some happy treatment as yet not resorted to as indicated in the foregoing notes, may possibly stay the advance of so serious a disorder of the motor neurons.

TWO CASES OF LOBAR PNEUMONIA FOLLOWING ETHER ANESTHESIA, WITH UNUSUAL COURSE.

By W. S. SCHLEY,

of New York.

Assistant Surgeon, Trinity Hospital, Assistant Surgeon, St. Luke's Hospital, Out-Patient Service.

The following cases of lobar pneumonia occurred after the administration of ether for surgical operation, ventral suspension of the uterus and herniotomy. There was nothing unusual of note in anesthesia, operation or condition of patient preceding operation. The *post* operative course of each seems worthy of record; both cases developed typical lobar pneumonia upon the 1st and 3rd days respectively following operation. In each case the right lower lobe was the portion of lung involved. There were in both cases subsidence of temperature within 16

hours and beginning resolution within 2 days after the administration of a single large dose of calomel (20-25 grs.) The mercury was given within 16 hours of the initial rise of temperature and dry on the tongue. The cases occurred upon the surgical division of St. Luke's Hospital, one each in the services of Dr. Robert Abbe and Dr. F. H. Markoe, to whom I am indebted for permission to report the same. They were the only cases of pneumonia occurring upon the division after several thousand anesthetics extending over a period of about two and one-half years. A resume of the bedside notes and temperature charts is appended.

A. B. Hospital No. 48,066. Quite well nourished but neurotic female, aged 26, married, the mother of one living child with one still birth at term. Admitted to St. Luke's Hospital November 21, 1898. Her history was entirely negative except for the trouble for which she entered; retro-displaced and retro-flexed uterus with chronic endometritis. Physical examination of the chest entirely negative, urine negative, operation two days later, nitrous oxide followed immediately by ether, curettage and cellotomy with anterior fixation of the uterus. Duration of anesthesia about three quarters of an hour. The anesthetic was very well taken—pulse 90, respirations 24, at the close of operation. During the two succeeding days the patient complained of slight pain in the right chest anteriorly and there was an occasional cough with some white mucus expectoration. She appeared nervous and anxious about her condition. One the third day "chilly sensations" in the early morning, more followed by a temperature of 104.4-5° and a respiration of 52 by 8 A. M. A yellowish purulent expectoration with frequent suppressed cough had replaced the mucus. By the afternoon a perfectly typical picture of a pneumonia, with an involvement of the right lower lobe, was present. There was a general bronchitis of the larger and smaller bronchi, moderate dusky color of skin. At 12 midnight she was given 20 grs. of calomel dry on the tongue (see chart). At 4 P. M. the succeeding day she was sweating profusely, the signs in the chest were unchanged and the temperature still elevated. From this time the pulse and temperature elevation began to fall. The leukocyte count showed 15,000 the following day when resolution began. Two days later the count showed 11,000. Resolution progressed slowly—twelve days later the lung had not cleared up. The patient (finally) made a perfect recovery with primary union in the abdominal wound.

ST. LUKE'S HOSPITAL

Figure 1

There was no purgation from the calomel. The expectoration was purulent throughout and contained no blood. Three days following defervescence it had largely ceased. The bronchitis cleared up long before the signs of the exudate into the lung. Labial herpes present. Chlorides in the urine were diminished during the attack. Albumen varied from a trace to 1%.

E. C. Hospital No. 48,727, male aged 31. Admitted March 4, 1899. History negative except for right inguinal hernia of several years duration. Physically he was an unusually well developed and muscular man and in good condition. Operation two days later—gas followed by ether anaesthesia of three quarters of an hour duration—pulse 72—respiration 18 on return to the ward. Between 8 and 12 midnight the temperature rise began, there was no chill—by 12 midday the signs of a right lower lobe pneumonia were present. There was a general bronchitis with moderately frequent cough—expectoration thick and purulent—skin very dusky—respiration apparently not however proportionately accelerated. At 5.50 P. M. he was given calomel grs. XXV. By 8 A. M. the next day he was perspiring profusely, the temperature had fallen to 100.3-34, the signs in the chest were unchanged. Expectoration the same—resolution began the following day but progressed slowly—expectoration ceased in about 5 days. In both of these cases there was a perfectly normal condition of the chest preceding the anesthetic as far as could be determined by the physical examination. There was no undue exposure before, during or following the operation. The anaesthesia was uneventful, the open Allis inhaler was used

The fall in the count in the case examined was slow, corresponding to the delayed resolution. The above cases are reported because they seem sufficiently interesting. The marked and *persistent* physical signs, characteristic temperature, behavior of the patient and leukocyte count make, I think, the diagnosis very certain. The use of mercury in this connection is very old, comparatively little literature has appeared upon the subject in the last 50 years. There is reason to believe that a certain number of patients have been benefited by such treatment. A large class undoubtedly will not be. Whether the measure is one that should be tried in the majority of cases, or whether the subsidence of the disease in these cases was due to the drug or spontaneous abortion are matters with which this article does not attempt to deal.

Discipline in Tuberculosis.—In the *Journal de Médecine de Bordeaux* (1901, No. 16), Dr. Portes, Director of the Sanatorium of Gelos, Pau, describes the discipline necessary in tuberculosis. Every individual with phthisis must be taught what is best for him. This can be best accomplished in a sanatorium, which Professor Landouzy calls

Figure 2

after narcosis was induced. The clinical picture was typical of lobar pneumonia. The physical signs showed an involvement of the right lower lobe in each instance and sharply defined. The calomel was given early in the disease. There was no purging or salivation following the mercury. One case required a saline and enema additionally. Resolution began about 2 days after defervescence in each case and was somewhat prolonged, changes in breathing and especially dullness on percussion persisted for some days over the lobe. The bronchitis cleared up 5-6 days following defervescence. The pulse, characteristically full at the beginning, remained of good force—there was no irregularity of rhythm or intermittent character preceding defervescence.

The apparent early cessation in the progress of the disease so soon after the administration of a comparatively large dose of calomel seems significant and worthy of consideration. The disease developing in cases already under observation made it possible to administer the mercury at an early date. It is to be regretted that no leukocyte count was recorded in the second case until the temperature was nearly normal, and that more were not made.

the school for the tuberculous. This is especially necessary for those who have never taken care of themselves, those who are treating themselves, with the advice of friends, and those who have acquired the bad habit of living isolated, absolutely alone. They will be encouraged in a sanatorium, will rest, receive good advice only, find good air, amusement and atmosphere of gaiety and companionship new to them. Naturally, some patients cannot long live happily in a sanatorium. But they will have learned how to live when they leave; hygiene, diet, rest, exercise, etc., having been regulated to suit each individual case.

[M. O.]

A Case of Natural Small-pox in an Infant of 3 Days Old.—B. P. Voitseehowski reported to the Pediatric Society of *Ann. Leitch, Vol. VIII, No. 1*, the case of an infant who developed on the **third day** of its birth an elevation of temperature and an eruption which became pustular on the sixth day. A diagnosis of **small-pox** was established. The mother had been vaccinated and was at the time perfectly healthy. The period of incubation being 10 to 14 days, the author believes that intrauterine infection took place in this case. He is also of the opinion that vaccination of the mother does not protect the fetus *in utero* against small-pox. [A. R.]

The Reorganization of the American Medical Association.—We had no adequate idea, until we read the report of the Committee on Organization, that the American Medical Association is such a loosely organized body that it is hardly capable of attending to its business. It is, in fact, so unwieldy and so uncertain in its membership and has such a limited time at its disposal, that it is in part deprived of its true usefulness and influence as a great national representative of the medical profession. According to the Committee, it has less than seven hours a year in which to transact its business. Its potential membership depends largely upon the locality in which it happens to meet, for this is one thing in Atlantic City, another in St. Paul, and still another in San Francisco. Finally, the Association is so hurried that it has not had time in the last ten or twelve years even to reform itself; this is shown by the Committee in its narrative of the former abortive efforts at reorganization. The trouble with the Association is that it is too large and too unstable. It urgently needs reorganization, and its best friends demand it.

We can approve without hesitation the scheme of reorganization now proposed. Minor details may be criticised, but the main plan is broad and statesmanlike. This plan proposes a House of Delegates, which shall be the Legislature of the Association. In effect, this body will be a Section on Business and will have nothing to do but to attend to business, and will have sufficient time in which to do it. If the American Medical Association has wisdom (and time), it will surely consider this proposition or some simple modification of it, favorably. Such a legislative body being elected by the State Societies on a basis strictly of numerical strength, would be purely representative and responsible, and would not be a fluctuating and indeterminate body, such as the main Association is too apt to be. Such a plan is closely in accord with the ideas which have created the best representative bodies in the world—as, for instance, in the State and in the church. For a body which may soon number 20,000 members to proceed on the old plan, somewhat like an old-fashioned town meeting, with a

referendum, is simply absurd. The Association needs a Legislature and should have it.

Concerning minor details, we should perhaps doubt the expediency, or at least the popularity, of conferring upon this House of Delegates the whole elective power of the Association. We believe that, in the main, it is the best for a society (medical or political) to elect its own officers and not have them elected for it. But this is a detail for the American Medical Association to settle for itself. The central, pivotal idea is that the Association must be better organized than it is at present.

Pancreatitis.—Mr. Mayo Robson, in his valuable article upon pancreatitis, published in another column of this week's issue, calls attention to the ignorance of this subject that exists in the profession as a whole, an ignorance fostered, we fear, by the studious neglect of this organ in the current textbooks of medicine and surgery. Although we undoubtedly know more of the physiology of the pancreas than of the thyroid, for example, yet the symptomatology of its diseases is so indefinite and confused that it has hitherto been a very unsatisfactory field of research. If Mr. Robson will accomplish for it what Kocher has accomplished for the thyroid gland, he will deserve the lasting gratitude of the medical world.

Mr. Robson calls attention to the importance of injury as an etiological factor. We have long suspected that the sickening sensation following a blow on the epigastrium was the result of bruising the pancreas rather than the solar plexus, as it is the fashion to believe. But our author believes that gall-stones are even more important in this connection. A priori, this seems not unlikely, for anything setting up an inflammatory condition of the common bile duct would naturally involve secondarily the duct of Wirsung.

The data upon which Robson relies for the diagnosis of pancreatic disease are very scanty. An abnormal amount of fat in the stools (a small amount is, of course, normal) is only a contributory symptom. Pain in the epigastrium and rapid emaciation are common to many conditions; for example, gastric carcinoma. Jaundice is merely the

symptom of a common complication. He apparently is unfamiliar with or does not value the disappearance of the ethereal sulphates from the urine. We should be inclined to place considerable value upon this sign. His remarks upon hemorrhage are of great interest. Admitting a pronounced hemorrhagic tendency, he does what few have hitherto attempted, and suggests an explanation. It is that the glycerin liberated in the process of fat necrosis is absorbed by the blood and interferes with coagulation. To our mind it would be more reasonable to suppose that the pancreatic juice that escapes into the tissues gives rise to the formation of peptones or albumoses, whose anticoagulant action is well known. In the treatment of the hemorrhagic tendency he employs chloride of calcium before and after operation, and for periods and in doses quite contrary to the prevalent teaching; that is, there is no stopping at the end of three days. He does not seem to be aware of the very excellent results obtained by Kehr in the treatment of cholemic hemorrhage by gelatin injections nor of the advantages claimed for the prophylactic injections of the same substance by Jaboulay.

Finally, we wish to express our heartiest admiration for the courage Mr. Robson has shown in breaking away from the old tradition, and classifying pancreatitis under the acute, sub-acute and chronic forms. Why the inflammation of this organ should differ so greatly from that of other glands has always been a mystery, and, like most other mysteries, apparently solely of human making.

Trichinosis as an Economic Problem.—At a recent meeting of the Philadelphia Pathological Society an important paper on this subject was read by Dr. Charles Wardell Stiles, of the Bureau of Animal Industry at Washington. Dr. Stiles' evident object was to demonstrate the futility of the German method of microscopic inspection of pork, and to prove that the presence of trichinosis in Germany is due to the German habit of eating raw meat. If the Germans would cook their pork they would not have trichinosis, and if they do not cook it they will continue to have the disease whether they eat American pork or some other pork and whether they inspect it or not. In other words, *trichinella spiralis* is not confined to American hogs, and it cannot be eliminated by microscopic inspection. In the first place, the disease is much less prevalent in America than in Germany. Dr. Stiles collected only about 900 cases in this country from 1860 to 1895, although he thinks the disease is rather more common than these figures indicate. The significant fact is that of 274 American cases in which the nationality could be determined, only four were in American-born persons, while 208 were in German emigrants.

This tells the whole story. Again, during the years 1883-1891, when American pork was prohibited in Germany, there were 4093 cases of trichinosis reported in the Empire with 274 deaths. The mortality for eighteen years was about 5%.

Dr. Stiles presents elaborate tables to prove that the system of meat inspection in vogue in Germany is not a success. He denies that the systematic attacks on American pork in the German agrarian press find any support in the accessible German health statistics. He points out that Virchow has not admitted some of the evidence against American pork as valid. Many cases occur due to faults in the inspection methods, and this fact leads Dr. Stiles to condemn the method by microscopic inspection as unreliable and extremely expensive. Prussia alone employed in 1896 an army of 27,602 inspectors at a great expense, and an adequate corps of inspectors for the United States would probably mean a tax upon the people of \$3,000,000 or \$4,000,000 per annum. The inspection method tends to foster a false sense of security, and hence encourages the people in their habit of eating raw pork. The only safety is in cooking the meat, and to this custom he attributes the comparative immunity of the American people. The *trichinella spiralis*, it will be remembered, was accidentally discovered in a ham-sandwich by Professor Leidy, of Philadelphia, in 1847; and Dr. Stiles does full justice to the fame of this eminent man and the momentous importance of his discovery.

A Trolley Ambulance Service.—The thought has probably occurred to not a few persons that a trolley car might be made into an ideal ambulance. The smoothness with which it can be run, and, above all, the quick time that can be made with it, are features which make it far superior to the horse-ambulance. Then it is much more roomy—a matter of importance in some emergency cases. Instances have occurred in this city in which the trolley has been used for ambulance service with most gratifying success. A few months ago a physician had occasion to bring a bed-ridden patient to her home in West Philadelphia from a location far out on the York Road. The distance was more than ten miles, and by horse-ambulance the journey would have been a long, painful and somewhat risky one. The happy thought occurred to the doctor to have a trolley car; and this was secured, and the patient moved with speed, comfort and safety. It is due to the Traction Company to say that in this case a very moderate charge was made—less, in fact, than was asked for the service of a hospital ambulance, although two men, a motorman and a conductor, were required. Probably not one-half the time was taken that would have been needed for

the ordinary ambulance, while the comfort (both physical and mental) to the patient was far greater. We think it would be a good idea for the Traction Company to have a completely equipped trolley ambulance. We have no doubt it would be patronized, were it once known.

Cryoscopy.—Cryoscopy may be defined as the determination of the osmotic pressure of liquids at their freezing-points. The lowering of the freezing-point is directly proportionable to the osmotic pressure of the liquid. Cryoscopy is a method introduced by Raoult, of Grenoble, for the purpose of measuring the urinary toxicity as well as furnishing enlightenment upon the metabolic changes in the blood, cerebrospinal fluid and pleural fluid. It has been found that the determination of the freezing-points of these fluids of the body present certain appreciable differences in certain diseases. The method has a wide field of usefulness both in experimental research and in the diagnosis and prognosis of disease. At present it is in its infancy, but the increasing reports of work done in cryoscopy bear out the originator's claims of its value. According to Cushny, osmotic pressure may be defined as the resistance offered by a non-permeating salt to the passage through the membrane of the fluid in which it is dissolved. When both salts in solution on the opposite sides of the membrane are unable to pass through it, the movement of the fluid is determined by the relative osmotic pressure on the two sides, water tending to pass from the solution of the lower osmotic pressure (*hypotonic solution*) to that of the higher (*hypertonic solution*). When an equilibrium is established between the two solutions they are said to be *isotonic*. In the animal body there is an analogue to the membrane and the salt solutions in the fact that the body-cells consist of colloid substances containing fluid and diffusible bodies, and are surrounded by liquids which are practically salt solutions, isotonic with the contents of the cells. Any changes in the cells or surrounding lymph give rise to certain movements of the fluids in the same manner as if each cell were surrounded by a membrane. The red blood corpuscles have been studied carefully in their action to certain salts. They are found to be permeable to ammonium chloride and impermeable to sodium chloride and other salts of the fixed alkalies. The study of metabolism involves a consideration of renal secretion, and it is in this work that cryoscopy has a physiological scientific value as well as a practical application to the physician. By its means we are enabled to determine the question of renal sufficiency or insufficiency. And it is found that in cases of nephritis there is a lowering of the cryoscopic point, and an elevation of that of the blood. Normal urine freezes

at about 1.35 C, indicating a mean molecular weight of 62-63 (Bouchard). Extremes in health vary from 60 to 68. In pathological conditions the mean molecular weight may vary from 68 to 112, sometimes the higher value indicates the presence of disease, such as syphilis, which otherwise might often be overlooked. The freezing-point of the blood varies little from -0.56°C . It is elevated in grave anemias and the cachexias, but lowered by accumulation of carbon dioxide in the blood and by the retention of excrementitious products. In the latter case oxygen does not cause the freezing-point to return to normal, while in the case of the accumulation of carbon dioxide, oxygen makes the freezing-point again -0.56°C . Acetone is found to lower it markedly, and the diet must be uniform in performing this method.

From the results of his experiments in cryoscopy, Léon Bernard believes that the renal permeability is normal, or even increased, in the early stages of parenchymatous nephritis, but the kidney has probably other functions, as yet unknown, which when disturbed cause the production of uremia. Waldvogel, examining the blood in typhoid fever, concludes that the higher freezing-point of the blood is not necessarily indicative of uremia. It is evidently not so much the quantity as the quality of the toxic substances retained in the blood that causes the disturbance in uremia. The freezing-point is higher in certain cases of typhoid fever, and Waldvogel makes the interesting observation that this is probably a phenomenon connected directly with the formation of antitoxin. In the cases in which the freezing-point is only slightly above normal—below -0.7°C .—the prognosis of the disease is generally unfavorable. Repeated cryoscopy of the fluid of a pleural effusion, it is claimed, will reveal the indication for intervention.

A Remedy for Sleeplessness.—Irreverent readers may smile when they learn that a college president has written a discourse on insomnia. Every clergyman is supposed to carry a simple remedy for this dread malady in his sermons, but the Rev. William DeWitt Hyde, of Bowdoin College, bravely ignores the possibility of jokes at his expense and writes very entertainingly in the *Outlook* about how to go to sleep. His method is somewhat complicated, and we will not spoil the description of it by paraphrasing it here. Sufficient to say, it consists in a sort of rhythmical breathing, with alternate closing and opening of the eyes. Dr. Hyde pleasantly says that he has not patented the process and intends to collect no fees for it, but he would like to hear by mail from all persons who find it efficacious. It is based upon a rather well-known fact that the quality of rhythm, or the monotonous repetition of

an act, has a soporific effect. Counting in imagination a flock of sheep, one after the other, jump over a fence, is based on the same principle.

A Philadelphia Specialty.—The *New York Sun* has recently been having a little fun with this city on the subject of appendicitis. After quoting from a prominent Philadelphia surgeon, it comes to the conclusion that the Quaker City is the center and capital of that disease. This is a distinction which we will try to support with becoming modesty. We do not doubt for a moment that by reason of the brilliant work of her surgeons, Philadelphia is the capital not only of appendicitis, but of all kinds of surgery as well. This has ever been so and doubtless will continue to be so. The fact that a metropolitan newspaper has discovered this truth is greatly to its credit. The *Sun* says that rich Philadelphians can afford to have appendicitis, and they do have it; but they seldom die of it. This, we affirm, is evidently because they have Philadelphia surgeons to attend them. The causes assigned for the prevalence of appendicitis here and hereabouts are the low-lying land (home of "miasma, hay-fever and grip"), and the athletic pursuits of the inhabitants. Golf, cricket, and bicycling in excess, disturb the equilibrium of the appendix. But the *Sun* affirms that a little appendicitis is not too high a price to pay for out-door sport, and it evidently believes that the proper thing for the victims everywhere to do is to resort to the "capital" of the disease for care and treatment.

The New Medical Laboratories of the University of Pennsylvania.—The problem of the combination of undergraduate instruction with post-graduate research work is always a difficult one for any institution to solve satisfactorily. A school that is concerned in giving elementary instruction to undergraduates places a great strain upon instructors and professors and makes a great demand upon its financial and material resources. With the system of concentration of the curriculum recently introduced by the faculty of medicine of the University of Pennsylvania, a step toward the practical solution of this problem has been taken. By condensing the time during which the undergraduates claim the energies of the teaching staff, that staff is freed for a portion of the year to devote its energies to research and to the direction of original work by advanced or graduate students. This step is now to be followed by another step of great importance. The trustees of the University have decided to provide the necessary laboratories in which this advanced work can be carried on, as well as modern and commodious laboratories in which the undergraduates may work, together with lecture halls

and demonstration rooms under the same roof. The new building, according to the plans submitted, is a two-story, oblong structure, with a central courtyard, the long sides of which face north and south, thus securing a maximum amount of the best light. The first floor will be devoted to laboratories of physiology, pharmacy and pharmacodynamics. The arrangement of the building is so carried out that the rooms for advanced work are entirely separate from those used by the undergraduates. There are separate rooms for professors and demonstrators, as well as the necessary store-rooms, etc. The entire second floor is to be devoted to pathological laboratories. In the front of the building, along the entire north side, there are small private rooms for research, as well as a room for the professor. In the back of the building there is a large laboratory for the study of pathological histology, as well as smaller rooms devoted to neuropathology, comparative pathology and surgical pathology. The west end contains the laboratory for advanced bacteriology, a pathological museum, a room for demonstrations in morbid anatomy, a room for microphotography, and store-rooms for supplies and microscopes. In the east end there is a large laboratory for experimental pathology and a laboratory for advanced pathology. The lecture rooms occupy a separate extension from the south side of the building and the demonstration rooms are in the center of the courtyard between the north and south sides of the oblong. It is the purpose of the trustees of the University of Pennsylvania to equip these laboratories with all the apparatus that modern knowledge has shown to be necessary to the successful pursuit of these branches of medical education. This plan will put the University of Pennsylvania in possession of a plant that will be without a rival in this or other countries, so that the undertaking is one not only of local, but also of national importance. We look forward with much pleasure to the completion of this elaborate scheme and extend our best wishes for complete success to the University of Pennsylvania in its undertaking.

The Fate of the Uterus in Abdominal Section.—A matter which, like Banquo's ghost, constantly recurs to haunt the pelvic surgeon, is the question of the disposal of the uterus after the operation of double salpingo-oöphorectomy. Again and again do we see the disconsolate victims of pelvic disease returning to the office or clinic room with the recurrence of all their distressing symptoms—minus the formation of pus-sacs—after the removal of their uterine appendages. In a small, and a very small, proportion of these cases will recovery ensue after a tedious course of intrauterine treatment covering a period of months or years. Many of these unfor-

fortunate women wander from hospital to hospital and from surgeon to surgeon, in the vain quest for health, and become the deplorable subjects of chronic hospitalism, an eye-sore to the doctors and an incumbrance to themselves, their families and the community. Discouraged by the failure of the first operation, they often refuse, even when urged, to submit to another abdominal section. Pelvic surgery suffers in repute from these failures to cure, and the individual surgeon loses thereby a portion of his prestige. Naturally, we ask, what is the remedy for this matter? Should the uterus be removed whenever the appendages—tubes or ovaries—are removed? Or are there certain cases only in which the more extensive extirpation may be performed? It would be as dogmatic to lay down a positive statement in one direction as in the other. The surgeon who states that the uterus after extirpation of the appendages is a useless organ, a menace to the woman, and therefore should be removed when its adnexa are lost, is making just as sweeping a statement as is his colleague, who claims that in the absence of marked apparent uterine disease the organ should always be retained. In other words, there is a radicalism that is too radical as there may be a conservatism that is dangerous and therefore reprehensible. A close investigation into the uterine condition in the unfortunate class of women referred to almost invariably shows a chronic form of endometritis and metritis very often associated with an extensive parametritis, that can be remedied only by removal of the offending organ. Often it will be found to be of gonorrheal or tuberculous origin. Now it stands to reason that a local tuberculosis wherever found is a menace to health, and should be removed as quickly as detected. A tuberculous endometritis is as dangerous as a cheesy lymph-gland or a tuberculous testicle. The local disease may at any time light up a general conflagration that will quickly destroy the patient. Again, the curious anatomical relationship of the utricular glands makes the eradication of gonorrheal infection practically impossible, while a streptococcic invasion of the parametrium, resulting in the development of tubal or ovarian abscess, may so deteriorate the vitality of the tissues around the uterus that a cure is possible only after extirpation of that organ, whereby thorough evacuation and drainage of the infected region will be secured. Unfortunately, the pelvic conditions are so obscure that it is beyond the power of the operator in every given case to state positively what is the degree of infection and what the probable outcome of a simple removal of the appendages will be. A careful study of the scrapings of the uterine cavity will solve the question in a certain portion of the cases. The condition of the

parts at the time of operation will be the guide in another proportion. The operator must in other cases be influenced by the ability of his patients to stand the graver operation of hystero-oöphoro-salpingectomy. The following rules may, however, be laid down as safe to follow: 1. The uterus should be removed in every case in which the tubercle bacillus is discovered in the uterine scrapings. 2. In every grave double tubal affection of gonorrheal origin, extirpation of the uterus would seem to be indicated, since the simple excision of the appendages removes but a portion of the diseased tissue and leaves the balance to become a source of trouble and suffering to the patient. 3. In extensive involvement of the broad ligament by the streptococcus subsequent to parturition at term or premature expulsion of the ovum, the uterus should be removed in order to afford free pelvic drainage.

The Trouble at Gallipolis.—It is much to be regretted that pathological laboratories, established and supported by the State, cannot be conducted without disastrous factional fights. Following hard upon the trouble in the New York Pathological Institute, there now comes word of a violent quarrel over the pathological laboratory in the Ohio Hospital for Epileptics at Gallipolis. Each faction is led by a medical man, and each of these at our request has sent us his own version of the affair. Dr. A. P. Ohlmacher, who is favorably known for his scientific work at Gallipolis, states that he was summarily discharged by Dr. H. C. Rutter, the manager of the Hospital, for the alleged but false reasons that he had failed to publish anything for a year past, and that the expense of his salary was too great. He claims that he has made seven contributions to science within the year, but he does not give their titles. Dr. Rutter charges broadly that Dr. Ohlmacher has neglected his work, and that he does not contribute enough to science to justify the expense of his salary. Each man charges that his opponent is identified with a political faction in an effort to keep control—and this is the one point upon which they both entirely agree. Dr. Rutter asserts that he himself has been the virtual founder and supporter of the laboratory, securing appropriations for its maintenance and meeting the criticisms of the politicians—a thankless but indispensable office, and one which is too little appreciated by impractical editorial critics.

Governor Nash, of Ohio, has very abruptly settled the trouble by refusing to allow Dr. Ohlmacher to be discharged, and by discharging Dr. Rutter instead. It thus appears that Dr. Ohlmacher is triumphant, and he claims that the result is a victory for science, while Dr. Rutter says that it is a victory for politics. The duty now seems incumbent upon

Dr. Ohlmacher of meeting the charge that he has been neglecting his work—a task which we should suppose not to be difficult. His reputation is excellent, and he owes it to himself and his specialty to keep it so. We do not presume to sit in supreme judgment on the case. The exact merits of the quarrel, we confess, are not entirely clear to us, but we wish sincerely that it had not happened. It weakens the cause of science.

The Cause of Rheumatic Fever.—The older theories, that rheumatic fever is due to lactic acid, advanced by Prout, and its nervous origin advocated by John K. Mitchell, in 1831, have given place to the more generally accepted view, that the disease is of an infectious character. The frequency with which the disease occurs in the same house and its prevalence in large communities have been emphasized by many writers to support the latter theory. News-holme, in 1805 (Milroy Lectures), advanced important statistical evidence to prove its infectious nature and showed that the mortality and frequency of rheumatic fever fluctuate in a manner similar to those of erysipelas and scarlet fever.

In 1891 Bouchard and Charrin claimed to have often found the staphylococcus pyogenes albus in the affected joint-fluid of subacute and chronic cases. In 1893 Saint Germain succeeded in producing joint inflammation with cultures of staphylococci by intravascular inoculation. The following year Sacaze suggested that the tonsils were the channels through which infection occurred. Singer, in 1895, reported a number of cases, in which staphylococci were found in the urine in ten cases and twice in the blood; streptococci in the urine in three instances and the streptococcus pyogenes with the staphylococcus pyogenes albus in the urine in two cases; while in one instance he found the staphylococcus pyogenes aureus. Chbostek did not succeed in finding micro-organisms in the urine in nine out of twelve cases. Sahli isolated the staphylococcus pyogenes citrus from the blood, synovial membranes of the joints and the pericardial and endocardial exudates of a fatal case of rheumatic fever. Sternberg sustained the view that pus cocci are responsible for the disease, the infection occurring when the natural immunity of an individual is lost.

We especially wish to direct attention to the important investigations of Poynton and Paine (*Lancet*, May 4th, 1901). These observers have isolated a diplococcus from sixteen cases of rheumatic fever. In a brief summary of their work they state, that in three rheumatic nodules, taken from two cases, they have demonstrated this diplococcus; in one instance they succeeded in isolating the micro-organism from the nodule in pure culture, and

that intravenous inoculation of this culture in a rabbit produced polyarthritis, pericarditis, and valvulitis. The diplococcus was again isolated from the joint-exudate of this animal. They maintain that the rheumatic nodule should be regarded as a highly characteristic manifestation of the disease. They also suggest the association of this infection with the commencement of rheumatic chorea. In October, 1900, these investigators reported a case which they believed to be chorea in a rabbit, due to the intravenous injection of this diplococcus. The animal presented definite, sudden, involuntary movements, which are so characteristic of rheumatic chorea, and also developed polyarthritis and valvulitis. In the brain of the animal were found diplococci,—in the endothelial cells of the blood capillaries of the motor cortex and in the pia mater. In the last named structure there was also slight cellular proliferation and cellular swelling. From these observations Poynton and Paine conclude that the presence of this diplococcus lends strong support to the view that it is the specific cause of rheumatic fever.

Hospital Contagion in Typhoid Fever.—The possibility of direct contagion in typhoid fever has again been discussed at a recent meeting of the Medical Society of the Paris Hospitals (*Bulletins et Memoires de la Societe Medicale des Hopitaux de Paris*, 1901, No. 4). Troisier reported the case of a patient with dilatation of the stomach, in whom lavage with unboiled, filtered water, was performed daily. 37 days after admission, typhoid fever developed. As there were 9 cases of typhoid in the ward, it is possible that direct contagion occurred, though the water used for washing out the stomach might have been contaminated. Le Gendre, in his thesis, in 1886, noted that dilatation of the stomach was favorable to the invasion of infectious diseases, especially typhoid. In a surgical ward, in the same hospital, three cases of typhoid also developed. Troisier could find no possibility of contagion here, and believes that these cases were due, probably, to drinking contaminated water. Ballet reported the case of a patient in his charge, who, with her nurse, frequented a public bath. During the struggling in the water, not only the patient, but the nurse also frequently swallowed water. Both developed typhoid at the same time. Letulle reported 7 cases occurring in persons who had been a long time in the hospital, three maternity patients, and four nurses. Two of the nurses were on duty in the typhoid ward. In none of the other cases was any mode of contagion found. Catrin (*Medecine Moderne*, 1901, No. 16.) has reported two cases in which direct contagion seems probable. A nurse in attendance upon a typhoid fever patient was accustomed to sleep with her head

resting upon the patient's bed. She was taken ill three weeks after she had begun nursing the case. A friend of hers, who often came in to speak to her and shook hands, developed typhoid a month afterward. None of the patients in the neighboring ward were affected. There is no doubt that sporadic cases of typhoid fever may appear in hospitals just as they do elsewhere, for direct contagion can be proved in but a small number of cases. Yet, as contagion is possible, Catrin pleads that every case of typhoid be isolated. He believes, as in mumps, that all that is necessary is a closed door.

On the Influence of the Cervical Sympathetic on the Frequency of the Movements of the Heart in Man. F. Wertheimer and H. Gaudier, *L'Echo Medical du Nord*, Feb. 24, 1901, 50me. Annee, No. 8.

In the case of a woman, aged 24 years, who was suffering from exophthalmic goiter, Gaudier resected both cervical sympathetics at an interval of 7 days. The authors found in this patient that the cervical sympathetic had no action upon the heart. It may be objected that the frequency of the heart's action was already augmented and that the excitation of the accelerator nerves could add nothing to it. But the tachycardia in the patient was not exaggerated. [J. M. S.]

Three Cases of Poisoning by Cannabis Indica.—Kossobudski, (*Medycyna*, Feb. 24, 1901; *Vratch*, Vol. XXII, No. 11), reports the following cases: (1) A woman of 36, suffering from chronic metritis and salpingitis, received an infusion and subsequently fluid extract of *cannabis indica* in doses of 10 drops twice daily. After taking the infusion the woman felt gastric pain which became unbearable after a repeated dose of the fluid extract. She became greatly excited and uncontrollable, prayed loud and called for help. Washing out the stomach and internal administration of bromides relieved her. (2) A woman of 20, suffering from a flexed uterus and perimetritis, received 5 drops of *cannabis indica* 3 times daily. In a few days she developed extreme irritability and a maniacal state, accompanied by trembling of the extremities and burning in the stomach. She was relieved by lavage and bromides. (3) A woman of 20 with an endometritis was treated by *cannabis indica* in doses of 8 drops of the fluid extract 3 times daily. Symptoms of poisoning developed after the first dose. In view of the above cases the author advises that the dose of the infusion of this drug should not exceed 5 to 7 drops. [A. R.]

Spinal anesthesia. 1. W. M. Mintz reported before the Society of Russian Surgeons which had its first meeting in Moscow (*Medicinskoie Obshrenie*, February, 1901,) 4 successful cases of medullary anesthesia. 1% solution of cocaine was used. Anesthesia appeared within 6-8 minutes and lasted for one hour. In one case, however, the internal abdominal viscera failed to become anesthetized and chloroform had to be resorted to. No complications or untoward effects were noticed. 2. At the same meeting I. Ia. Meerovitch reported 78 cases. The strength of the solution used was from one-fifth to 4%. In 17 the operation was performed on the extremities, while the other 35 were gynecological and included several laparotomies. In 50% of the cases the anesthesia was followed by headache lasting for 2-3 days. Vomiting was less frequent than with chloroform. Retching was quite frequent and interfered considerably with the operation. An elevation of temperature lasting for 6-8 hours was observed in a number of cases. Herpes labialis was another complication, and in a few instances involuntary discharge of urine took place. In a few cases clonic and tonic spasms of the lower extremities occurred 6-7 hours after the injection and lasted for 18 hours. By using strong solutions of cocaine together with sodium bromide better anesthesia was obtained and the untoward effects were slight. [A. R.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

New Quarters for a Children's Hospital.—The Children's Hospital, which has been located on East Price street, Germantown, for nearly two years, will remove shortly to No. 47 West Penn street.

The University of Pennsylvania is about to erect, at a cost of more than \$500,000, exclusive of grounds and equipment, a medical laboratory building which will be unexcelled in every respect. The subject is treated editorially in the Philadelphia Medical Journal.

Location of Hospital Causes Protest.—At a special meeting of the Pay Hospital for Contagious Diseases held at Philadelphia May 24, a protest from prominent property holders at Narberth against the locating of the institution in the borough was considered. The ground on which the protest is made is that the institution would injure property values. It is urged on the other hand that all possible precautions to prevent danger to outside persons would be taken, that there could not be any danger, and that the arrangements would be passed on by the State Board of Health.

Colleges will Nominate Candidates.—At the meeting of the Department of Charities and Corrections, May 24, a resolution was adopted which provides that hereafter the eligible lists of applicants for positions of resident physicians in the Philadelphia Hospital shall be submitted to the various medical colleges of the city, and that the University of Pennsylvania, the Jefferson College and the Medico-Chirurgical College be requested each to nominate seven candidates, and the Woman's Medical College three candidates, for election by the Board. John M. Scott took his seat in the Board as successor to Mr. Dingee, resigned.

Jewish Hospital Association.—At the thirty-sixth annual meeting of the Jewish Hospital Association, held on May 26th, the following officers were elected to serve during the ensuing year: President, William B. Hackenburger; Vice-President, Hon. Mayer Sulzberger; Treasurer, August B. Loeb; Secretary, Ephraim Lederer; Corresponding Secretary, Herman Jonas; Directors, Dr. L. W. Steinbach, Maurice Bamberger, Joseph L. Greenwald and Hyman H. Ginsburg. Jacob Wiener, having completed ten years of continuous service as a member of the Board, became an honorary Director.

Philadelphia County Medical Society.—The meeting of May 22 was devoted to the address of the retiring President, Dr. John H. Musser, his subject being *Streptothrix infections*. Dr. Musser said that actinomycosis and madura foot were no longer the only infections of that class which were recognized. He reviewed the literature and gave the results of investigations of various observers. The lungs, brain, and skin are the organs most often the seat of these infections. In the lung they give rise to broncho-pneumonia, bronchiectasis, abscess, empyema, etc. In the nervous system they are chiefly the result of metastasis and in the brain they give rise to abscess, meningitis, softening, etc. From the clinical standpoint there is but little that is new in these cases. The pulmonary cases are often hidden under tubercular symptoms or those due to other infections. The finding of the streptothrix settles the diagnosis. Bacteriologically the streptothrix is between the moulds and bacteria. Of the most importance to the clinician is the finding of mycelial tufts or granules in the lesions or the sputum. Many instances are probably unrecognized. Dr. Musser reported 2 cases of streptothrix infection. Case 1 was a nervous case in whom there was at first an unaccountable rise of temperature. The pulse was quickened, but the only lesion found was that of a moderate bronchitis. There was a moderate degree of anemia with no leukocytosis. Sputum was obtained with difficulty. The physical signs of broncho-pneumonia developed, the temperature rose to 105° and death followed. The sputum was found to contain a few thin tubercle bacilli and in addition branching filaments and rod-like bodies which showed some tendency to branching. These were undoubtedly the streptothrix but were very few in number and were found only when stained by Gram's and the Ziehl-Neelson methods. Case II was important, as showing how large areas of the brain may be affected without producing

localizing symptoms. The patient was seized with headache and soon afterward fell unconscious for a time, a second attack, both resembling epilepsy, ensued. Other than a slight hypesthesia of the right side there was no evidence of brain involvement as shown by localizing signs. The patient finally went into collapse. Lumbar puncture gave relief, no bacteria being found in the fluid. A repetition of the puncture produced no change and the patient died one week from the date of the first convulsion. Autopsy revealed an abscess cavity in the brain $3\frac{1}{2}$ cm. in diameter and contained a chocolate-colored, foul-smelling fluid. Examination showed no tubercle bacilli in the fluid, but one bunch of long thin filaments with suggestion of branching was detected. A careful study of the abscess wall was made, 100 sections being made before a mass of the same streptothrix filaments was found. At least 150 more were made before a second bunch was seen. Otherwise the pus and cavity wall were sterile. This shows how the streptothrix may be overlooked, as it probably is in many cases. Two thoughts suggested by these cases were given by Dr. Musser in conclusion: (1) Many of the so-called sterile abscesses may be due to a streptothrix infection. (2) Abscesses of various forms, especially in the brain, occur without fever. These also may be due to the streptothrix.

Philadelphia Pathological Society.—At the regular meeting held May 23, Dr. M. P. Ravenel exhibited: (1) **scabies in rats.** Scales containing the characteristic parasites were found on the tip of the nose, the ears, and the tail of the animals. The several varieties of the disease are all probably due to one organism but differ in the manifestation according to the mammal infected and the thickness of the skin. (2) **Unusual types of tubercle bacilli.** Two cultures on dog's blood serum and glycerin were shown. The first contained a great amount of fat. To get a spread from this culture it was necessary to first melt the growth. It however, stained but slightly with sudan III and not at all with osmic acid. The second culture showed a jet black and also a greenish growth from absorbed pigment from the media.

Drs. W. M. Welsh and J. F. Schramberg exhibited specimens from a case of variola. The first was an area of skin taken from a patient who died on the twelfth day. The pustules were discreet and all umbilicated. It was stated that the old view of the umbilication being caused by the resistance of the hair follicles and sweat ducts was now being discarded for the view that it is caused by a difference in the rapidity of necrosis. The stomach and esophagus were also shown. These were interesting from the fact that the former was deeply injected, almost hemorrhagic, while the esophagus was extremely pale. The line of junction of the two conditions was very distinct at the cardiac orifice. The esophagus also contained small ulcers which were probably vesicles.

Dr. R. M. Pearce spoke of the increase of connective tissue in the lung in chronic passive congestion. Dr. Pearce said that the increase in the lung in cases of chronic congestion is an increase in the elastic tissue. The studies demonstrating this fact are made possible by Weigert's stain. The increase in elastic tissue is most marked at the points where it normally exists. The function of the new tissue is to support the blood vessels (thus aiding circulation) and the air vesicles. Dr. Flexner said that the increased rigidity of the lungs in cases of chronic heart disease was due to an increase in elastic tissue. Dr. Pearce said that this increase of elastic tissue could be found in all viscera which were the seat of chronic passive congestion.

Drs. F. A. Packard and Simon Flexner exhibited a specimen of probable primary intestinal tuberculosis in an adult with multiple metastases. The appendix was greatly enlarged and metastases were found in every viscus of the body. Some doubt as to the lesion being primarily intestinal was occasioned by the fact that at the apex of the left pleura there was a marked thickening, although no caseation was found in the adjacent lung.

In the meninges very young tubercles, macroscopically invisible, were found. There was also a tuberculous area in the left optic thalamus.

Dr. W. F. Hendrickson exhibited a Teratoma of the testicle.

Drs. W. S. Wadsworth and W. F. Hendrickson exhibited a specimen of Tuberculosis of the Heart.

Vital Statistics of Philadelphia for the week ending May 25, 1901:

Total mortality	421	Cases.	Deaths.
Inflammation of the appendix 2,			
bladder 1, brain 15, bronchi 7,			
heart 2, kidneys 22, liver 1, lungs

NEW YORK.

The New Mount Sinai Hospital.—The corner stone of the new Mount Sinai Hospital buildings, Fifth avenue and One Hundredth street, New York City, was laid on May 22 with beautiful ceremonies. After the presentation of a silver trowel, Mr. I. Wallach, president of the Mount Sinai Hospital, pronounced the corner stone of what promises to become one of the finest hospital structures in New York City, "well and truly laid." Governor Odell, of New York, who was to have been present and deliver an address, was prevented from so doing on account of illness in his family. Addresses were held by Hon. Seth Low, of Columbia University, Hon. Randolph Guggenheimer, president of the Council of the City of New York, and Hon. Edward Lauterbach. No distinction of race or creed will be made.

The American Orthopedic Association will meet at Niagara Falls, N. Y., on June 18th, 19th and 20th.

Appointment.—At a recent meeting of the Board of Hospital of Buffalo, N. Y., Drs. Lucien Howe and Julius Pohlmann were appointed oculists.

The Library of the Medical Society of the County of Kings, of Brooklyn, N. Y. which was founded A. D. 1845, reports that on May 19, 1900, the Library contained over 30,000 volumes, 15,000 pamphlets and some 500 current medical periodicals, all of which were free to the public. In addition to the very best publications, the collection is especially rich in classics. The earliest printed volume is a folio published A. D. 1474. The first donation to the permanent library was the "Dr. John Lloyd Zabriskie Memorial Library Fund," presented in 1899 by Mrs. Zabriskie as a memorial of her husband, the late Dr. John Lloyd Zabriskie.

New York Neurological Society.—Stated Meeting May 7, 1901.—John Collins, M. D., President.—A Case of Successful Mental Treatment of a Form of Hysteria.—Dr. Mary

Putnam Jacobi reported this case. The patient was a woman of twenty-four, belonging to a neurotic family. Her symptoms had begun four years before coming under observation by an endometritis and uterine retroflexion. She had been subjected to a good deal of local treatment, including curettage and an Alexander's operation. The latter procedure had relieved the dysmenorrhea, but had been followed by a fixed pain in the abdomen not increased by pressure. She claimed to be unable to walk or stand because of severe pain in the back and abdomen which it induced. Examination showed no motor inability, and when started to walk she could walk very readily and energetically. The uterine disease had entirely disappeared. She was moderately anemic and quite constipated. The speaker said that at some portion of the cerebrospinal tract an area of nerve tissue must be so nearly on the border of exhaustion that an attempt at function carries it beyond this line. It was conceivable that with the exhaustion of the cerebral centre the very thought of the movement would be followed by pain. According to Sanier such hysterical pains point to a partial anesthesia in the brain. Apart from the intermittent pains excited by the sense of walking there seemed to be a permanent and distressful sense in the back, requiring support. In a previous experience with a bed-ridden patient she had succeeded in making her walk within a week by the application of a Taylor spinal brace. This simple device had given great relief. The necessary nerve stimulus has been secured by the application of static electricity. This remedy seemed to be almost a specific for hysterical pains. The subject of the present report had been persuaded to leave her home and take a room near Dr. Jacobi's office. At first, it was not difficult to get her to walk a portion of a block, but when finally asked to walk a whole block she obstinately refused. All sorts of changes in the treatment and methods of management were necessary in order to conquer the patient's wilfulness, yet this was essential to further progress. Her mode of life for each day was mapped out most minutely. By the most persistent and painstaking efforts exerted for a period of four months the patient was finally conquered. During the last eighteen months she had been living a fairly normal life. Dr. Jacobi said that in hysterics the habitual dependence upon fellow minds is immensely intensified. To get rid of a false idea it must be starved out and atrophied by an entire lack of support from the minds of those around the patient. The essential element of the treatment of this case was the bringing of the personality of the patient under the control of another mind.

Dr. B. Sachs commended the general plan of treatment described in this paper, though admitting that it required far too much expenditure of time and attention to detail to make it generally available.

The Morbid Anatomy of a Case of Progressive Muscular Atrophy which was Clinically one of Amyotrophic Lateral Sclerosis.—Dr. Carlin Philips read this paper. He said that the patient was a woman of thirty-six, who had come under Dr. Collin's observation for the first time on June 17, 1897. She had then complained of severe frontal headache, inability to lift the head from the pillow without the help of the hands, tremulousness of the hands, and easily induced fatigue. She had lost thirty pounds. Examination showed atrophy of the supraspinatus and of the right shoulder girdle, and these muscles showed fibrillary twitchings. The knee jerks were increased; there was ankle clonus on both sides; there was no affection of the special senses. Six months later she had complained of dyspnea and had shown loss of will power and suicidal impulses, together with some difficulty in swallowing. The atrophy of the muscles was more marked, and extended to the trapezius muscle. She began about this time to have attacks of major hysteria, and the atrophy increased rapidly. The gait became spastic and the body rigid. She had the use of her limbs up to about six weeks before death on May 25, 1899. An autopsy was allowed only upon the brain and spinal cord. The weight of the body was forty-eight pounds. The meninges of the brain were anemic. The brain was normal in gross appearance, as was also the spinal cord. The latter was carefully segmented and prepared in various ways for examination. In the second cervical segment was a concentric zone encircling each anterior horn and involving the anterior mesial and anterior lateral portions of the fundamental columns, while the tracts of Gowers and the pyramidal tracts were left intact. Corresponding to the degenerated areas in this segment the neuroglial proliferation was very slight. The fourth cervical segment showed

a sinking in of the periphery just at the margins of the anterior roots, and this change of contour extended down several segments. The gray matter extended laterally, giving a sickle-shape to the degenerated area. While there was no evidence of the destruction of the cells, the most striking feature was the extensive destruction of these cells. The fifth cervical segment was practically the same as the fourth. The sixth segment showed a tongue-shaped area of degeneration extending almost to the posterior horn. In the seventh segment the anterior roots showed more marked degeneration. From the first to the fourth dorsal segments inclusive there was a zone of degeneration encircling the anterior horns, and becoming less intense until almost invisible in the fourth segment. The disappearance of the motor cells throughout these four segments was more difficult to determine than in the case of the cervical segments but apparently there was about the same amount of atrophy of these cells. From the fifth to the eighth segments there appeared to be an increase in the neuroglial tissue. From the twelfth dorsal down to the end of the cord the area occupied the peripheral lamina of the ventral half of the cord, and extended around to a point opposite the apex of the lateral horn, where it expanded into a lateral mass. The lumbar and sacral regions were found to be as severely involved as the cervical. Throughout the cord the blood vessels were apparently normal. Nissl preparations of the medulla showed small areas of periarthritis with small cell infiltration of the adjacent gray matter. The anterior roots were found to be atrophic. The crossed pyramidal tracts were apparently unchanged.

NEW ENGLAND.

The National Association of Life Insurance Medical Directors will hold their annual meeting at Hartford, Conn., May 28-29.

New Hospital.—By the will of George Griffin, of Shelton, Conn., two-thirds of the residue of his estate, amounting to about \$25,000, is left to establish a hospital for the benefit of Shelton and the towns of Seymour, Ansonia and Derby.

WESTERN STATES.

The International Association of Railway Surgeons will meet at Milwaukee, Wis., on June 10th, 11th and 12th.

The American Dermatological Association will hold its twenty-fifth annual meeting at the Beach Hotel, Chicago, Ill., May 30 and 31 and June 1, 1901. Twenty-five papers and reports are on the program of the first two days. The morning session of the third day will be devoted to the exhibition of patients.

Dr. Winslow Appointed.—Gov. Yates has appointed Dr. Frederick C. Winslow, of Jacksonville, to be superintendent of the hospital for incurable insane, now nearing completion at South Bartonville, a suburb of Peoria, the appointment to take effect as soon as the hospital is opened to patients, which will be about October 1. Dr. Winslow is at present superintendent of the Jacksonville asylum, and is an insanity expert.

The California Eye and Ear Hospital, San Francisco, established four years ago, has outgrown its present quarters, and will erect a new \$20,000 building. Dr. Tension Deane is President, and Dr. Redmond W. Payne, Secretary.

Appointment.—Henry Sheridan Keys, M. D., has been appointed Surgeon-in-Chief to the Emergency Hospital, now building at Los Angeles, California.

A "Healer" in the Meshes of the Law.—The Coroner's Jury in Chicago which for two days had been listening to the testimony of witnesses in the case of Mrs. Emma Lucy Judd, who was associated with John Alexander Dowie's Zion, returned a verdict holding Dowie, H. W. Judd, husband of the woman, Mrs. Sprecher and Mrs. Bratsch to await the action of the Grand Jury. The two women named in the verdict were in attendance upon Mrs. Judd prior to her death. The charge against them is "criminal responsibility" for the death of Mrs. Judd. The evidence given at the inquest by some of the leading physicians of the city who had examined Mrs. Judd's body after it had been exhumed, was to the effect that the most simple surgical care would have prevented the woman's death. They testified that she was allowed to die when the slightest attempt to save her life would have been successful. Papers were at once made out and officers sent to arrest Dowie, Judd and the two women.

SOUTHERN STATES.

The *Chicago Inter Ocean* states the following: Dr. Dudley S. Reynolds, one of the founders of the Louisville Hospital College of Medicine, and a member of its faculty from its inception, has been dismissed from the institution because of his antagonism to cigarette smoking. He is now suing Central University, of which the medical school is a part, for \$15,000 damages. Dr. Reynolds, in his lectures to his classes, denounced cigarette smoking and smokers in unqualified terms. The students took offense and refused to attend his lectures unless an apology was made. This he declined to do. At this juncture the faculty joined with the students and requested his resignation. Again he declined, and his dismissal followed.

Richmond.—Among the recent changes which have taken place at the close of the session of the University College of Medicine, Richmond, Va., are the election of Dr. H. I. McLean to the Chair of Histology and Pathology, vice Dr. M. D. Hoge, Jr., resigned, and that of Dr. A. L. Gray to the Chair of Physiology.

The *Savannah Academy of Medicine* has recently been permanently organized in Savannah, Ga., with the following officers: President, Dr. A. A. Morrison; vice-president, Dr. Frederick Wahl; secretary, Dr. J. Oliver Cook; treasurer, Dr. G. L. Harman.

CANADA.

(From Our Special Correspondent).

The Ontario Medical Council has extended the time limit to another month to those physicians who have been negligent in the past in paying their annual assessments. As a consequence of their first circular to the profession so in arrears there are now only some three or four hundred physicians in this province who have not met the demands of the Medical Council. The law against unregistered practitioners will most assuredly then be put in operation if compliance with this second mandate be not executed at once. The action of the Council has called forth innumerable letters to the lay press, and hot shot has been poured out *ad libitum* at the offending heads of this body. We may look for squalls after the 19th of June.

The **Grave Robbing Case** in which Mr. William Patterson, a third year student in medicine at Queen's University, was concerned last February, was disposed of on the 22nd day of May by his Honor, Judge Waller, of the Petersboro County Court. On the charge of opening the grave Patterson was adjudged "not guilty," the prosecution failing to prove that he had any connection with that part of the affair. On the charge of indecently interfering with a dead body, however, he was found guilty and fined \$200, or, in event of his failing to pay the fine, he was to be gaoled for the term of one year. The Ontario law provides for such misdemeanor a sentence of five years in the penitentiary or a fine at the discretion of the judge. Patterson's previous good character saved him from the heavier judgment. This is the first case of its kind ever before the Ontario courts.

A Suit for Malpractice.—It is very gratifying to notice the magnanimous manner in which the profession throughout Canada are coming to the assistance of Dr. J. M. Conerty, of Smith's Falls, Ontario, who has had to bear a prolonged defence in a suit for malpractice brought against him by the father of the boy, who had neglected following the doctor's instructions in the treatment of a case of Colles' fracture. That Dr. Conerty is wholly innocent of any malpractice has been abundantly proven to the satisfaction of the profession, and their financial sympathy bears full testimony of the fact. The statement has recently been circulated that Dr. Conerty, who has been financially crippled in defending this suit, had compromised for \$600. This is incorrect. He purposes continuing the fight to the bitter end. The Montreal Medico-Chirurgical Society, the Toronto Clinical Society, Dr. R. W. Powell, of Ottawa, and others, have come to his aid, and thus fortified, Dr. Conerty can continue the fight with vim, confident that his action is upheld by his professional brethren. This case particularly emphasizes the importance of immediate action being taken in establishing the long-talked-of Medical Defence Union in the Dominion of Canada.

The **Monthly Report of the Provincial Board of Health of Ontario** shows 2,247 deaths in April, as compared with

2,525 in March and 2,311 in April of last year. The deaths from contagious diseases were as follows: Consumption, 236; diphtheria, 39; scarlatina, 17; whooping cough, 14; typhoid fever, 12. The deaths from consumption and diphtheria show increases, the figures in April, 1900, being 203 and 24 respectively. Six deaths have occurred from smallpox so far during the present outbreak in a total of 600 or more cases. This means only one per cent. of those afflicted during the present epidemic. The per capita percentage is infinitesimal. Brides seem to think they have special immunity from smallpox. A wedding at Sault Ste. Marie was the cause of seven or eight cases: while a young girl recently escaped from quarantine at Havelock, Ont., fled to Auburn, N. Y., and was there married, but subsequently quarantined.

Bishop's Medical College, Montreal.—A number of changes have recently been made in the teaching staff of this institution and several new appointments made. Dr. F. W. Campbell, the dean, will in future give a special course of lectures in insurance law in addition to his regular lectures in medicine and neurology. As professor of medicine he will have associated with him Dr. J. B. McConnell, vice-dean, the chair being further assisted by Dr. W. E. Deeks, lecturer on internal medicine; Dr. A. G. Richer, specialist in pulmonary diseases, and Dr. W. Grant Stewart. Dr. Deeks is a new member of the staff. Dr. James Perrigo will continue to have charge of gynecology, and will have associated with him Dr. A. Laphorn Smith, who remains also professor of clinical gynecology; Dr. H. L. Reddy and William Burnett retain their professorships. Dr. George T. Ross, professor of laryngology and rhinology, who up to the present time has been registrar of the faculty, has been replaced as such by Dr. James M. Jack, a new member of the staff who will also lecture on dermatology. The chair of surgery is to be occupied by Dr. F. R. England, with whom will be associated as lecturers, Dr. F. J. Hackett and Dr. Rollo Campbell, and as instructors Dr. George Fisk and Dr. Herbert Tatley. Dr. Louis Laberge, Montreal's health officer has been appointed lecturer in hygiene to replace Dr. Richer. Dr. W. G. Reilly has been appointed to the chair of anatomy.

Winnipeg General Hospital.—The regular monthly meeting of the Board of Governors of the Winnipeg General Hospital was held in the hospital on the afternoon of the 20th of May. The report of the Committee appointed to arrange for a pathologist and bacteriologist was received and adopted. Arrangements were made whereby Dr. Gordon Bell, the provincial bacteriologist of Manitoba, should undertake all of this work connected with the hospital at the yearly salary of \$500. Dr. Bell to furnish at his own expense an assistant who must be present at the hospital daily for such hours as may be found necessary for carrying on this work. Dr. Bell will assume his duties on the first of June. Dr. Chestnut, the medical superintendent asked to be allowed to resign. This was permitted and Dr. Jasper Halpenny, who has been acting as assistant medical superintendent since February last, was appointed to the position of medical superintendent for one year from the 1st of June. Dr. Popham, secretary of the Board of Examiners, reported that nine nurses had passed the final examination in the training school. Nurse Macdonald received the Ogilvie prize for the highest general proficiency.

Public Works Health Regulations have just been adopted by the Dominion Government. They will provide for the preservation of health and the mitigation of diseases among persons employed in the construction of public works. Some few months ago an inspector was appointed to enforce the Act, and these new regulations define his duties. He is to act as chairman when present, of meetings of health boards, notify the Minister of Agriculture and secretary of the provincial board of health wherein public works are being carried on of all cases of infectious diseases in such works. Contracting persons or companies must engage a medical officer, who will attend the employes where the number is over 100, and does not exceed 500. An additional medical man is to be appointed where the number exceeds 500, the idea being to have a medical officer for every 500 men, each properly supplied with medicine and means of conveyance. The health board on such works will consist of the inspector, the medical officer or officers and the engineer. The regulations further provide for the establishment of hospitals in connection with such works to accommodate at least six patients. Isola-

tion hospitals for infectious diseases must also be provided.

Montreal General Hospital.—The annual meeting of the Governors was held last week. The Committee of Management recommended that on and after June 1st, 1901, a charge of ten cents should be made for the first bottle of medicine and five cents for each subsequent bottle in the out-door department. Dr. John McCrae was appointed resident assistant pathologist, and the engagement of Dr. Von Eberts as medical superintendent was extended to the 1st of May, 1902, his staff to consist of ten resident house doctors and a lady superintendent with seventy nurses. A complete new sterilizing apparatus with all the latest improvements has been put in at a cost of \$500. Dr. Finley, the secretary, reported that at the end of the year the expenditure had amounted to \$84,280; the income, \$75,994; indicating an excess of expenditure of \$8,286 for the year. This with last year's deficiency of \$14,149 makes a total deficit of over \$22,000 against the hospital. During the past year there have been in the hospital 3,178 in-door patients, of whom 2,823 were treated to a conclusion. The out-door patients numbered 41,606 against 33,373 the year previous. Two hundred and fifty died in the hospital during the year, 105 deaths occurring within three days of admission. The average number of patients per day was 178, and the average cost per patient per day was \$1.37.

The Ontario Medical Association will meet in Toronto on the 19th and 20th of June.

The Canadian Medical Association will meet in Winnipeg on the 28th, 29th, 30th and 31st of August.

Appointment.—Dr. Harriet Cockburn, Toronto, has been appointed physician to the new Victoria Asylum for Women at Cobourg, Ont., the first instance of a lady physician being appointed to a similar position in Canada.

Dr. T. H. Little died at Toronto, Canada, on April 25th, from hemorrhagic smallpox, contracted while attending one of his patients. He was a graduate of the Toronto School of Medicine, and had been in active practice in Toronto for twelve years.

Dr. Thomas Ritchie Almon, one of the foremost physicians of Nova Scotia, died in the city of Halifax, on April 25th. He was a graduate of King's College and also of the College of Physicians and Surgeons, New York.

Medico-Chirurgical College Commencement.—At the commencement exercises of the Medico-Chirurgical College, held at the Academy of Music on May 25th there were 69 graduates in medicine. The following medals were awarded:

Faculty gold medal, for highest general average, Senior Class, to Dr. Evan W. Meredith.

Faculty gold medal for best thesis, to Dr. Morris C. Thrush.

Faculty gold medal for highest general average, Junior Class, to Hardie Lynch.

Faculty gold medal for highest general average in Sophomore Class, to Donald G. McCaa.

Faculty gold medal for highest general average in Freshman Class, Robert J. Hunter.

Gold medal given by Professor James M. Anders for the best report of his medical clinics, to Dr. Harry Lowenberg.

Gold medal by Professor Ernest Laplace for best report of his surgical clinics, to Dr. Ignatius L. J. Fitzpatrick.

Gold medal by Professor L. Webster Fox for best report of his ophthalmological clinics, to Dr. Morris C. Thrush.

Gold medal by Professor W. Frank Haehnien for best report of his obstetrical clinics, to Dr. Louis H. Jacob.

Prize given by Professor Elwood R. Kirby for best examination in genito-urinary surgery, to Dr. Clarence E. Gardner.

Prize for best examination in hygiene by a member of the Sophomore Class, to Warren C. Batroff.

The graduates honored by medals in the Department of Dentistry were:

Faculty medal to Arthur R. Dray for the highest senior average.

Faculty medal to Peter McAneny for the highest junior average.

Faculty medal to Frank W. Miller for highest freshman average.

Robert H. Nones medal to Arthur R. Dray for highest senior average in prosthetic dentistry.

Robert H. Nones medal to Warren H. Stover for highest junior average in prosthetic dentistry.

Robert H. Nones medal to Richard Souder for highest freshman average in prosthetic dentistry.

Walter H. Neall medal to Arthur R. Dray for highest senior average in operative dentistry.

George W. Cupit medal to Joseph Scott for highest senior average in dental pathology and therapeutics.

The award of medals in the Department of Pharmacy was as follows:

Faculty gold medal for highest general average in final examinations for graduation, to William F. Hennings.

Faculty gold medal for highest general average in Junior Class, to Lloyd W. Conrad.

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine Hospital Service for the Seven Days ending May 23, 1901.

C. T. PECKHAM, surgeon, granted leave of absence for 30 days from April 19, on account of sickness—May 16, 1901.

Granted 30 days' extension of leave of absence, on account of sickness from May 20—May 21, 1901.

A. H. GLENNAN, surgeon, to rejoin station at Habana—May 21, 1901.

C. P. WERTENBAKER, passed assistant surgeon, to proceed to Meridian, Miss., for special temporary duty—May 18, 1901.

J. B. GREENE, passed assistant surgeon, granted 5 days' extension of leave of absence—May 19, 1901.

C. E. DECKER, assistant surgeon, granted leave of absence for 10 days from May 11, on account of sickness—May 20, 1901.

TALIAFERRO CLARK, assistant surgeon, granted leave of absence for 30 days from May 22—May 22, 1901.

G. M. CORPUT, assistant surgeon, to proceed to South Atlantic quarantine—May 16, 1901.

Granted leave of absence for 1 month—May 16, 1901.

J. C. RODMAN, acting assistant surgeon, granted leave of absence for 4 days—May 18, 1901.

A. W. SLAUGHTER, acting assistant surgeon, granted leave of absence for 4 days from June 4—May 22, 1901.

Board Convened.

Board convened to meet at Washington, D. C., May 20, 1901, for the purpose of making physical examination of applicants for cadetship in the Revenue Cutter Service. Detail for the Board: Surgeon L. L. Williams, chairman; Assistant Surgeon B. S. Warren, recorder.

Changes in the Medical Corps of the Navy, week ending May 25, 1901.

P. A. SURGEON R. M. KENNEDY, ordered home via public conveyance.

ASSISTANT SURGEON M. V. STONE, detached from Buffalo, and ordered home to wait orders.

ASSISTANT SURGEON C. N. DELANCY, detached from Bancroft and ordered to the Buffalo.

ASSISTANT SURGEON F. M. FURLONG, ordered home by public conveyance.

ASSISTANT SURGEON D. B. KERR, ordered home by public conveyance.

ASSISTANT SURGEON E. J. CROW, ordered home by public conveyance.

ASSISTANT SURGEON A. C. CRUNWELL ordered home by public conveyance.

ASSISTANT SURGEON D. C. BEEBE, ordered home via public conveyance.

ASSISTANT SURGEON C. D. LANGHORNE, ordered home by public conveyance.

ASSISTANT SURGEON J. STEPP, detached from the Castine and ordered to the Isla de Luzon.

ASSISTANT SURGEON F. J. CROW, detached from the Isla de Luzon, and ordered to the Castine.

ASSISTANT SURGEON E. THOMPSON, detached from the Solace and to the Petrel.

ASSISTANT SURGEON R. W. PLUMMER, detached from the Petrel and ordered to the Nashville.

ASSISTANT SURGEON F. N. FURLONG, order detaching from the Brutus, and ordering him forward to Guam, L. I.

Abstracts of Papers and Discussions at the Annual Meeting of the American Surgical Association, held in Baltimore on May 7th, 8th and 9th, 1901, the President, Dr. Roswell Park, of Buffalo, in the Chair.

(Continued from Page 993.)

In addition to these fifteen cases that have passed the three-year-limit, 8 were mentioned in which the tumors disappeared entirely. One, a spindle-celled sarcoma of the abdominal wall, was well 1½ years, when the patient returned to her home in Europe and was lost sight of. Another, an extensive round-celled sarcoma of the iliac fossa, was well one year and then lost sight of. A third, a spindle-celled, recurrent sarcoma of the leg, is now in perfect health, without recurrence, nearly two years after treatment. A fourth, a twice recurrent, spindle-celled sarcoma of the palm of the hand, disappeared under the toxin treatment and the patient remained well 2½ years, when the tumor recurred. Refusing amputation of the arm, she was under the care of a Christian scientist for eight months, during which time the tumor in the hand reached the size of a coconut and extended above the elbow. Amputation of the arm just below the shoulder joint was then performed, but the patient died of metastasis 3½ months later.

A fifth case, a chondro-sarcoma of the ileum, of large size, disappeared and the patient, after remaining well

for seven months, had a recurrence which proved fatal in about a year's time. A sixth, a round-celled angio-sarcoma of the breast, was well six months later, when the patient was lost sight of. A seventh, a recurrent fibro-angioma of the lip, was well when last heard of, over two years after operation; and an eighth case, a spindle-celled sarcoma of the thigh, disappeared, but after a year's time recurrence took place locally and in the groin, which no longer yielded to the treatment.

In addition to the 24 personal cases, the writer mentioned 2 other cases in which he directed the treatment, although it was carried out by another surgeon. One case (Johnson's) a large, spindle-celled sarcoma of the pharynx, entirely disappeared, and the patient was well more than six years later. The second (Storr's and Griswold's), an inoperable sarcoma of the breast and axilla, disappeared under 76 injections of the mixed toxins, and is now well more than four years after treatment. The diagnosis in both of these cases was confirmed by microscopical examination, in the latter case by the highest authority in this country, Prof. William H. Welch, of Johns Hopkins University.

The writer stated that the results of this method during the last two years had given him no reason to change the conclusions expressed in earlier papers. His further experience has confirmed the opinion that spindle-celled sarcoma yields far better results than any other variety, although there have been a sufficient number of round-celled cases successfully treated, to make it advisable to give every inoperable case the benefit of a brief trial. If no improvement has occurred at the end of 3 to 4 weeks, with daily injections, the writer does not believe the treatment is likely to prove successful. If improvement does occur, the injections should be continued either until the tumor has entirely disappeared, or it has become evident that the toxins have lost their inhibitory influence. The toxins may be given for long periods in moderate doses, without harm to the patient. The risks of the treatment are practically nil, provided proper precautions are observed. In upwards of 200 personal cases there were but 2 deaths, both of which occurred more than 5 years ago. The percentage of probable cures depends largely upon the type of the cell, varying from perhaps 3 to 4 per cent. in the round, to nearly 15 per cent. in the spindle-celled.

Thus far, no permanent successes have been obtained in melanotic growths, nor in lymphosarcomas of the neck. The writer stated his belief that the toxins administered in small doses immediately after primary operations for sarcoma, offer a most valuable prophylactic measure against future recurrence. The results thus far, he stated, were sufficient to warrant advising the treatment as a routine measure after all operations for primary sarcoma. While the treatment is not recommended in carcinomatous growths, it has been the experience of the writer that in many cases the toxins exert a marked inhibitory influence in carcinoma, although it is rarely curative. The only cases of carcinoma in which the toxins are likely to prove of much value, he believes, are those in which they are used after primary or secondary operation, as a prophylaxis against recurrence. Up to the present time sufficient experience is lacking to justify one in making any definite statements as to how much may thus be accomplished.

The writer still believes that the action of the toxins upon malignant tumors can be explained only upon the theory that such tumors are the result of some infectious micro-organism, and this view is strongly supported by the recently expressed opinion of Czerny.

Dr. Joseph D. Bryant, of New York, read a paper entitled "The Influence of Mental Depression on the Development of Malignant Diseases," in which he dwelt at length on the history of cancer as affected by mental depression. Pare, in 1510, was the first man to refer to mental perturbation, anger and the like, as making a cancer "more fierce and raging," while the same authority under the head of treatment, insists that the patient must eschew fasting, watching, sorrows, cares and mourning. Sir Astley Cooper was of the same opinion, while Velpeau thought otherwise. Grant and Napoleon have been referred to as examples of cancer following reverses, and Paget and Virchow gave a qualified allegiance to the passive side of the question.

The foundations of the different phases of the contention rest on the beliefs (1) that cancer may result from the direct influence of mental depression (2) that cancer may

arise indirectly from mental depression because of the defective nutrition attendant upon it, and (3) that mental depression exercises in no respect influences that admit of sufficient proof to warrant serious discussion.

The author referred to the infrequency of cancer in insane patients, and stated that females suffered twice as often as males. Statistics were given from a number of institutions which showed that the death rate in the female was nearly double that of the male, although there were more male melancholics, but melancholia in the male does not seem to exercise any distinctive effect on the death rate. Neither is melancholia in the male more often associated with cancer than with other forms of malignant growths.

Many authors were quoted and the following division of the cases was suggested: (1) Cases in which mental depression is not associated with the idea of cancer; (2) Cases in which mental depression is associated with the idea of impending cancer of primary or secondary occurrences, and (3) Cases in which the depression is the outcome of common causes.

Afternoon Session.

Dr. J. Collins Warren, of Boston, in discussing the foregoing papers, stated that there were several different ways of approaching the question as exemplified by different writers, and referred to the geographical, statistical, histological, experimental, blastomycetic. The experimental was divided into chronic irritation and inoculation, and reference was made to the fact that two papers had appeared during the year in favor of the protozoan theory of the disease.

Reference was made to the experiment of Lack in producing peritoneal cancer in a rabbit by scraping the ovaries, which observation, so far as known has not been confirmed by any other observer.

Dr. Cullen closed the discussion on the foregoing papers and stated that in order to prove conclusively that a given organism is the cause of cancer it is necessary (1) to find or isolate the organism (2) to produce cancer by inoculating the organism into another body and (3) to recover the organism from the cancer thus produced.

He commented at considerable length on the work of Dr. Gaylord and hoped that he and his associates would not be discouraged in their work.

In closing the discussion Dr. Park stated that he had not said one-half of what he would like to say but he promised to give more details of the work in the future in a paper to be prepared by Dr. Gaylord and himself, dealing particularly with the methods and results of inoculation.

Dr. J. C. Bloodgood, of Baltimore read a paper on "Blood Examination as an Aid to Surgical Diagnosis," and illustrated the subject with a large number of statistics and tables.

The Clinical Value of Blood Examinations in Appendicitis: A Study Based on the Examination of One Hundred and Eighteen Cases in the German Hospital, Philadelphia, was the title of a paper read by Dr. J. C. DaCosta, Jr. The author discussed the subject under the heading of (1) Methods and Technique, (2) Classification and (3) the Anemia of Appendicitis. The details under each one of these headings were discussed at great length and a large number of blood counts were given both actual and comparative.

Drs. J. B. Blake, J. C. Hubbard, and R. C. Cabot read a paper entitled **Blood Examination in Relation to Surgical Diagnosis**, and divided the subject into six headings. (1) the leukocyte count in fractures, (2) Post operative leukocytosis, (3) Etherleukocytosis, (4) the effect of fear on the leukocytes, (5) Regeneration of the blood after operations on malignant tumors and (6) Blood examinations in relations to intestinal perforation in typhoid fever.

Dr. J. Chalmers Da Costa and J. L. Kaltefleiter, of Philadelphia read a paper entitled "The Effect on the Blood of Ether as an Anaesthetic." The paper reviews the rather meagre literature of the subject, dwelling particularly upon the writings of Mickuliz, J. Chalmers Da Costa, Oliver, Hamilton Fish and Bloodgood.

They dwell on the great difference which exists as to whether or not ether causes blood destruction. They hold that it does cause blood destruction and that those who affirm the contrary have been misled by the blood concentration which results from the preliminary treatment and which is often added to by sweating during the anesthetic

state. This blood concentration may mark the fall of hemoglobin; in fact in some cases will cause an apparent rise. The important facts to note are that the color index practically always falls and that the number of corpuscles increases. These facts prove marked blood destruction and increased production of corpuscles deficient in hemoglobin, resulting from ether anesthetic. The authors report upon 50 cases in which blood examinations were made and subdivide these cases into numerous tables for purposes of examination and comparison. In 49 of the cases the color index was lowered. The writers also showed sections of the marrow of a rabbit's femur, the animal having been etherized to death. These sections show mocked erythroblastic proliferation.

The authors conclude that the hemoglobin is absolutely reduced after the administration of ether, this reduction being manifest in the individual corpuscular hemoglobin value. The increased hemolysis which occurs in nature's effort to rapidly replace the destroyed corpuscles and the regenerated cells are imperfectly supplied with hemoglobin. The authors urge that whenever possible one or two blood examinations should be made before ether is administered and these examinations should be made before preparatory treatment has been instituted. If less than fifty per cent. of hemoglobin is present an anesthetic is dangerous and should only be given in a surgical emergency, which threatens life. In malignant disease a percentage of under fifty per cent. contraindicates operation. Mickuliz says no general anesthetic should be given under any circumstances if the hemoglobin is under thirty, but the authors believe that forty per cent. is probably the lowest justifiable limit. If operation must be performed when the hemoglobin is under forty per cent. a local anesthetic should be given. It is true cases with under forty per cent. of hemoglobin are occasionally etherized successfully, (for instance, one case was recalled with only twenty-four per cent.), but such instances are rare, are not sufficiently numerous to set aside the rule and are only justified by the imperative necessities of a vital emergency. Whenever the percentage of hemoglobin is low the administration of the anesthetic should be entrusted only to an experienced man, as little ether as possible should be given, the surgeon should operate quickly and proper measures should be adopted to bring about reaction promptly and to remove the ether from the lungs and blood as quickly as possible.

Dr. John B. Deaver, of Philadelphia, read a paper entitled "Examination of the Blood in Relation to Surgery of Scientific Value, but Too Often of no Practical Value and May Misguide the Surgeon."

The subject of appendicitis was discussed in detail and the value of the microscope in bedside diagnosis was referred to, but the author felt that too much importance should not be attached to this as compared with the weight given to other signs of the disease, some of the latter possessing in his opinion greater merit as aids to the surgeon.

In his discussion on the foregoing papers Dr. B. Farquhar Curtis, of New York, remarked the frequency of leukocytosis following either anesthesia and stated that it occurred quite as often after intraspinal anesthesia. He did not believe that leukocytosis should be considered as demonstrating the existence of infection, but rather that it should be looked upon as a fixed factor following anesthesia, illustrating this point by reference to a case. While he considered this point of great value, he felt that the temperature and pulse record were equally so.

Second Day, Morning Session.

This session was held at the Johns Hopkins Hospital and addresses were made by Drs. Osler and Welch. Demonstrations were also given by Dr. Kelly in the employment of the newer methods of diagnosis in rectal and urinary disease and by Dr. Young in catheterization of the male urethra. Dr. Osler's remarks referred to the clinical and Dr. Welch's to the laboratory methods of teaching employed at the Johns Hopkins.

Dr. Oscar H. Allis gave a demonstration of fractures of the pelvis. He demonstrated upon the cadaver the effects of violence directed against the pelvis through the medium of the femur, being a comparative study of the relative strengths of the neck of the femur and that of the pelvis. The application of force was by means of a lever driving the head of the femur against the acetabulum, directed

(a) at right angles to the long axis of the trunk and (b) parallel to the long axis of the trunk.

Afternoon Session.

Dr. A. W. Mayo Robson, of Leeds, England, read a paper entitled "Pancreatitis with Especial Reference to Chronic Pancreatitis." The author commented on the fact that he thought it strange it had not until recently dawned on the minds of clinical observers that whatever obstructs the common bile duct at its lower end must also of necessity lead to obstruction in the pancreatic duct. When the common bile duct is obstructed the objective signs of jaundice at once demonstrate the fact but hitherto no pathognomonic sign has been discovered which will show conclusively that the pancreatic ducts are occluded, unless it be the extremely rapid loss of weight. When it is borne in mind that the pancreatic duct opens along with the common bile duct into the second part of the duodenum it is not a matter for surprise that pancreatitis should be met with. The essential and immediate cause of the various forms of pancreatitis is bacterial infection, which has been positively proved both clinically in the human subject and experimentally in the lower animals. The association of gall-stones with chronic pancreatitis was absolutely forced on my mind by the frequency with which I found inflammatory enlargements of the head of the pancreas when operating for gall-stones in the common duct.

Taking up the subject of fat necrosis it was stated that this condition is commonly found in association with pancreatitis and the relationship between the two conditions has given rise to much speculation.

Hemorrhage in pancreatic diseases was dwelt upon and it was mentioned that death from collapse may occur either immediately or some hours after spontaneous hemorrhage. Several illustrative cases were cited, together with the symptoms and results, the following conclusions being reached: (1) that in certain diseases of the pancreas there is a general hemorrhagic tendency, which is much intensified by the presence of jaundice; (2) that hemorrhage may apparently occur in the pancreas unassociated with inflammation or with jaundice or with a general hemorrhagic tendency; (3) that both acute and chronic pancreatitis can and do frequently occur without hemorrhages, and (4) that some cases of pancreatitis are associated with local hemorrhage.

It was suggested that pancreatitis should be divided into the acute, sub-acute and chronic and that the hemorrhagic be considered a variety of the acute. The glycerine set free in the tissues by the fat necrosis was looked upon as a possible cause for the local hemorrhage and some details on this point were gone into. In addition, the results of blood examinations with a view of discovering, if possible, the cause of the hemorrhagic tendency were given.

The treatment of the three stages of the disease was then discussed fully and examples given of each, together with the results of treatment, as well as of post-mortems.

Dr. George E. Brewer, of New York, in discussing Dr. Robson's paper on Pancreatitis, stated that he believed the disease to be of far more frequent occurrence than is generally supposed and in support of this assertion he cited the records obtained from the autopsy table, as showing its serious nature, frightful mortality and obscure symptomatology, as well as the fact that certain surgeons, as the author of the foregoing paper, have had a large personal experience with the disease and, where it has been extensively discussed, a fairly large number of cases have annually been reported. The fact of its non-recognition by the profession at large is established by the fact that, in other localities, no cases are reported. He stated that in going over the recent annual reports of fifteen or twenty of New York's largest hospitals he found but one which recorded surgical treatment of the disease, and in this one institution four cases are reported as having been operated upon during a single year.

He believed the profession failed to recognize this disease more readily for two reasons; (1) their attention has not been directed to it by reports of cases and monographs on the subject and (2) sufficient data have not been collected on the subject and (2) sufficient data has not been collected accurate and complete catalogue of the characteristic symptoms. He dwelt upon the importance of constant vigilance being maintained for this disease and the value of recording and publishing the clinical histories and results of operations, together with the autopsy findings of all cases of this dis-

order coming under the surgeon's observation. This, he felt, would be of great value to the profession at large, enabling them to diagnose the condition much more readily. The anatomy of this region could be renewed with great interest not only in regard to the clinical history and pathology of the disease, but might furnish some very valuable suggestions in reference to treatment. At a very early period in the development of the embryo pancreas is formed by two offshoots from the intestinal tube just below the gastric dilatation between the two layers of the posterior mesentery. These two branches rapidly develop and again divide and subdivide, forming an innumerable number of fine twigs, each one ending in a small epithelial-lined sac. These are surrounded by minute plexuses of blood vessels, nerves and lymphatics and held together by areolar tissue which divide the gland into a large number of segments or lobules. The further development of the pancreas was then discussed at some length and the development of another outgrowth which afterwards forms the liver was noted. The different stages in the development of the bile duct and the two pancreatic ducts were recognized and the fusion of the lower pancreatic duct with the bile duct forming the ampulla of Vater, which opens into the duodenum in the adult subject was remarked. He referred to the fact that the older anatomists taught that the upper pancreatic duct gradually atrophied and only remained patent in a few instances, but later investigation resulted in the discovery that it could be injected from the main pancreatic duct in about fifty-six per cent. of the cases and still later investigation by improved methods demonstrated the fact that the duct of Santorini is practically always present in the human subject. He then presented five or six photographs furnished him by Dr. Carlton Flint of the anatomical department of Columbia University, showing the arrangement and accessory in some of the lower animals as compared with those of the human body. He then called the attention of the society to the fact that in the early stage of its development the pancreas is completely invested by the peritoneum and only becomes a retroperitoneal organ by the absorption and conversion into areolar tissue and fat of the several layers of the posterior mesentery. The attention of the society was directed to the four different routes by which the pancreas may be reached, namely: by dividing the gastro-hepatic omentum just above the lesser curvature of the stomach, (2) by dividing the gastro-colic omentum just below the greater curvature of the stomach, (3) by dividing the transverse mesocolon, and (4) by reflecting the parietal peritoneum through a lumbar incision until the peri-renal fat is reached, which is continuous with the areolar tissue surrounding the pancreas. He then mentioned the fact that in his opinion a probable causative relationship existed between an enlarged and relaxed duodenal orifice of the ampulla of Vater due to the frequent passage of biliary calculi and inflammatory diseases of both the bile duct and the pancreatic duct, stating that he based his opinion upon observations regarding the existence of like conditions in other portions of the body of ducts emptying into septic cavities in other portions of the body. In concluding he mentioned the probable digestive action of the pancreatic juice when allowed to percolate into the connective surrounding the gland as a cause of erosion of the blood vessels and extensive necrosis in addition to the well known power it has of producing fat necrosis.

(To be Continued.)

Obituary.—Dr. Frank C. Hoyt, at Kansas City, Mo., on May 21.—Dr. Marie J. Mergler, at Los Angeles, Cal., on May 18, aged 50 years.—Dr. Hugh Stockdell, at Petersburg, Va., on May 23, aged 66 years.—Dr. R. A. Gottsleben, at Mayville, Wis., on May 23, aged 50 years.—Dr. Conrad Weinges, at Jersey City, N. J., on May 23, aged 53 years.—Dr. John T. Hagan, at Baltimore, Md., on May 23, aged 51 years.—Dr. Jane Kendrick Culver, at Boston, Mass., on May 23.—Dr. Thomas F. Rumbold, at St. Louis, Mo., on May 23, aged 71 years.—Dr. George Washington Whitney, at Chicago, Ill., on May 23.

Smallpox Delays Troops.—Further cases of smallpox have been discovered on the United States transport Indiana, and the Ninth Infantry Regiment, which left Pekin May 22, on its way to Manila, has gone into camp at Taku.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

(Continued from Page 991.)

Edward L. Trudeau, of Saranac Lake, N. Y., read a paper entitled the importance of a recognition of the significance of early tuberculosis in its relation to treatment. The search for the tubercle bacillus should be begun early and continue as long as the symptoms remain obscure. The absence of the tubercle bacillus from the sputum is not conclusive evidence of the absence of the disease, particularly in its early stages, and too much stress should not be laid upon the negative finding. The tuberculin test is of value in reaching a conclusion when the bacilli are not found. The results of the tuberculin test are most reliable when the patient has no fever. Early diagnosis is of the first importance in the treatment of the disease, because it is in the incipient stage that the greatest amount of good can be done. Although the open-air treatment of tuberculosis gives renewed hope to physician and to patient, disappointment will result unless the importance of early diagnosis is realized. In answer to a question by McPhedran, of Toronto, the author said that a regular rise of temperature to 99.5° at a definite time of day is of significance in a case of suspected tuberculosis. A. Jacobi, of New York, said that mouth temperature in cases where accuracy is a desideratum is unreliable. Rectal temperature is the only one that can be absolutely relied upon. Even in the rectum there is a difference of ½° between the lower and the higher portions of the rectum. Rectal temperatures of 99.5° are normal. Some cases with prolonged expiration and impairment of resonance are due to interstitial pneumonia of long duration. Edward L. Trudeau said that in a case such as cited by Jacobi the tuberculin test would give conclusive demonstration as to the nature of the disease. He begins to inject one mg. of tuberculin for diagnostic purposes, then gives 3 mg.; and finally, 6 mg. In surgical cases it is often necessary to use between 5 and 15 mg.

J. George Adami read for J. McCrae, of Montreal, a paper entitled a study of a series of cases of burns. The paper is based upon the study of 13 cases of burns, 4 of which came to autopsy. In burns it is possible that a toxemia is produced which is similar to the toxemias of bacterial origin.

Focal necroses are not a constant accompaniment of burns. The lymph-nodes sometimes present a clear central portion with a cortex closely packed with cells; and, in other instances, there is degeneration throughout. The proliferated endothelial cells in the lymph-nodes are phagocytic and the author interprets the clear center that he has seen as a later stage than the necrotic center described by Bardeen. The lymphocytes in such a lymph-node have disappeared by a combination of toxic and phagocytic action. In cases of severe burns the kidneys were the seat of degenerative changes. The liver, also, showed various changes that were similar to the condition seen in other toxic states. The pathological processes present a similarity to the diseases characterized by the presence of toxins in the blood. The damage to lymphatics in burns is constant but not necessarily focal. The focal lesions are not true necroses but are due to the proliferation of the endothelium of the capillaries. Simon Flexner, of Philadelphia, said that Bardeen's investigations were suggested by the similarity of the lesions found after burns and those accompanying diphtheria. The changes in burns are more proliferative than degenerative. The appearances of degeneration may indeed be due to phagocytosis but in the toxemias the degenerative changes are complete. A. Jacobi, of New York, asked whether there was any relation between the changes described and the physical changes such as the conversion of hemoglobin into methemoglobin. The kidneys are usually the seat of a hemorrhagic nephritis when methemoglobin is present in the blood. William H. Welch, of Baltimore, said that probably the toxin elaborated in a burn is due to the action of heat on the blood in the superficial capillaries. He could accept the granules found in the lesions of the lymph-nodes as the result of the digestion of lymph-cells by endothelial cells. The process then would be that the manufactured toxin stimulates the fixed endothelial cells to proliferation and they take up the lymphoid cells by phagocytic action. It would seem more reasonable to suppose, however, that these phagocytic cells were utilized to remove lymph-cells already damaged by toxin.

S. J. Meltzer, of New York, read a paper entitled **hemolysis**. The author has found that immunized serum consists of 2 substances: one of which is stable, the other of which is destroyed by heating to 55°C. The latter substance is a ferment-like body, which causes a precipitate in fresh serum. Hemolytic serum, during its stay in the peritoneal cavity, loses its enzyme-like complement.

The following papers were read by title: **Slow pulse with special reference to Stokes-Adams' disease**. By Robert T. Edes, of Boston.

Exhibition of a cardiograph and a kymographion for bedside use. By Alfred Stengel, of Philadelphia.

A case of acute leukemia presenting some interesting features. By D. D. Stewart, of Philadelphia.

Masked malarial infection. By Morris J. Lewis, of Philadelphia.

Sarcosporidia of the mouse (*sarcocystis muris*) transmitted directly by feeding muscular tissue. By Theobald Smith, of Boston.

A further report on a case of presystolic mitral murmur associated with systolic tricuspid murmur complicating pregnancy reported to the association in May, 1899. By James Tyson, of Philadelphia.

The extension of aortic aneurysms into and between the walls of the heart and dissecting aneurysm of the heart. By Ludvig Hektoen, of Chicago.

A study of bacteria isolated from cases of dysentery. By F. F. Westbrook, of Minneapolis.

The relative prevalence of Bright's disease in New York, London and Berlin. By Hermann N. Biggs, of New York.

Lithemic or recurrent coryza. By B. K. Rachford, of Cincinnati.

Report of a case of spondylosis rhizomelia with autopsy. By Charles L. Dana, of New York.

The relation of the tracheal tug to fixation and elasticity of the left lung. By Henry Sewell, Denver.

The following officers were elected for the ensuing year: President, James C. Wilson, of Philadelphia; vice-president, J. Stewart, of Montreal; recorder, S. Solis-Cohen, of Philadelphia; secretary, Henry Hun, of Albany; treasurer, J. P. Crozer Griffith, of Philadelphia; councillors, Frank Billings, of Chicago, and Francis P. Kinnicutt, of New York; member of the executive committee of the American Congress, William Osler, of Baltimore; alternate, Francis H. Williams, of Boston. [J. M. S.]

Second Day, Afternoon.—William A. Park, of New York, read a paper entitled **To what extent is urine a suitable soil for bacterial growth?** The paper is based on the study of 50 urines to determine their fitness to be used as a culture medium for microorganisms. The author found that in highly acid urines the majority of microorganisms would grow with difficulty and that some would not grow at all. He suggested that if a urine was rendered highly acid by suitable medicinal substances it might help to prevent infection and be of assistance in the therapeutics of cystitis.

Francis P. Kinnicutt, of New York, read a paper entitled **orchitis complicating typhoid fever**. He reported 2 cases that he had seen in his wards in the Presbyterian Hospital in New York. One of the patients was a man, aged 24 years. The orchitis developed after convalescence was established and was accompanied by phlebitis of the long saphenous vein of the same side. The spermatic cord was involved. The second patient was 34 years old. The disease was apparently cured and then recurred. During the recurrence an abscess developed, the pus of which contained the bacillus of Eberth. It is possible that the bacilli reached the testicle through the blood current as well as through the vas deferens from the bladder. The condition is a rare complication of typhoid fever; the testicle seldom contains microorganisms; it usually occurs late in the course of the typhoid fever and is usually unilateral. William Osler, of Baltimore, spoke of a case of orchitis complicating typhoid fever that illustrated its late occurrence. F. H. Shattuck, of Boston, had seen one case in his hospital service recently and at the same time there were 3 cases in the service of his colleague, John H. Musser, of Philadelphia, had seen a case of orchitis in a boy who had not been sick in bed. The presence of the serum reaction explained the nature of the condition. While the patient was under treatment for the orchitis he had a relapse of his typhoid fever. Francis H. Williams, of Boston, said that he had seen a similar case to the ones

reported by Kinnicutt. Baumgarten said that he had seen one case accompanied by phlebitis of the internal saphenous veins during a relapse in typhoid fever. The vein was involved before the testicle.

Francis H. Williams, of Boston, read a paper entitled **notes on the treatment of some forms of cancer by the X-rays**. In employing X-rays for the treatment of carcinoma of the skin, great care should be taken not to produce burns. The cases treated by the author include epithelioma of the lip, of the hand and of the eyelid. The advantages of the treatment are (1) that there is no pain, (2) that there is no delay on account of dread of the knife, (3) that healing can occur without caustic effect, (4) that the results from a cosmetic standpoint are excellent and (5) that the treatment is ambulatory. The disadvantages of the method are (1) that great care is required, (2) that it is expensive and (3) that the treatment must be continued for some time.

In reply to a question from Charles S. Bond, of Richmond, Indiana, the author said that the X-rays are the active agent in the treatment and not the cathode rays. There is no disadvantage in placing a cloth between the growth and the Cooke's tube. In answer to a question by Peabody, of New York, he said that all cases except one had been submitted to microscopic examination. The cases were consecutive.

Frederick A. Packard and J. Dutton Steele, of Philadelphia, read a paper entitled **osteitis deformans**. The patient was a German, aged 62 years, who had a large box-shaped head with a projection in the frontal region and a tumor at the junction of the frontal, parietal and temporal regions. The circumference of the skull was increased. The clavicles were thickened and projected backward. The attitude of the patient was like that of an Orang Outang. At autopsy the calvarium was much thickened, the diploe were absent except in the frontal and occipital regions. The pituitary body and supranasal bodies were unaltered. The clavicle cut and decalcified easily. The processes of bone absorption were taking place in localized areas in both the calvarium and the clavicle. The tumor was a giant-celled sarcoma and nodules from the pia mater of the brain and the pleura presented the same lesion.

William Osler, of Baltimore, read a paper entitled **the spinal form of arthritis deformans**. There are 2 varieties of spinal involvement in arthritis deformans: one described by Bechterew, is characterized by rigidity of the vertebral column, kyphosis in the thoracic region and nerve-root symptoms. The other form was described by Marie and is characterized by involvement of the large joints at the proximal extremities of the limbs and the absence of nerve root symptoms. The author has seen recently 2 cases of the former and 3 of the latter type. In the 2 cases of Bechterew's type, the nerve-root symptoms were agonizing. In the 3 cases of Marie's type, complete thoracic immobility was present. The ligaments in the vertebral column may be completely ossified. The cases, in the opinion of the author are a variety of arthritis deformans and are not examples of separate diseases. Charles G. Stockton, of Buffalo, showed the skeleton of an intemperate man who had suffered from gonorrheal rheumatism which rendered him so diseased that he was unable to move. The skeleton is an excellent example of the changes found in the second type of case described in Osler's paper. The thorax is absolutely immobile, the right temporomaxillary joint is ankylosed, the segments of the vertebral column, the ribs and the hip joints are firmly ankylosed. Lamb, of Washington, showed a prehistoric skeleton from Alaska, obtained from the communal house, in which the spinal column was completely ankylosed, and in which there were kyphosis and complete bony union between the spinous processes in the lower thoracic and lumbar regions. The ribs were not ankylosed. He also showed specimens of bones from a skeleton in which all the bones were involved in the process except those of the vertebral column. B. Sachs, of New York said that he considered these cases to be a varieties of arthritis deformans. He referred to a case illustrating the early stages of the Bechterew type. J. P. Crozer Griffith, of Philadelphia, referred to the case of a woman, aged 71 years, who had had enlargement of the head since the age of 64. He showed the calvarium, which was very much thickened. The bones of the pelvis were thick and friable and the bones of the upper and lower extremities were thickened. He also referred to the case of a child, aged 8 years, who had a large head

and in whom the limbs were involved. The case was diagnosed syphilitic osteitis, but that diagnosis is not satisfactory. Cabot, of Boston, thinks that the productive and the destructive lesions are 2 distinct diseases. He spoke of the great advantage to be had by supporting the spinal column for the relief of the spinal symptoms. James J. Putnam, of Boston, spoke of a case that seemed to have had its origin in gonorrheal rheumatism. He also thinks that mechanical support of the vertebral column is of great value in the treatment of the condition.

B. Sachs, of New York, read a paper entitled **certain trophoneuroses and their relation to vascular disease of the extremities**. Erythromelalgia, scleroderma and Raynaud's disease often merge into each other. The author cited the case of a man, aged 27 years, who was suffering from Raynaud's disease, involving the feet and when he changed his occupation to one in which he had to use his hands, Raynaud's disease developed in his upper extremities. In this case there was an obliterating phlebitis in both the upper and the lower extremities. In a second case, a man aged 31 years, erythromelalgia was present. Following an operation for ingrowing toe nail an infectious process developed and amputation was necessary for gangrene. In this case there were arterio- and phlebosclerosis. There were slight changes of neuritis in the anterior and the posterior tibial nerves. The relation of vascular disease to trophoneuroses seems, from these instances to be apparent. Whether the vascular changes are primary or secondary is open to discussion. E. G. Janeway, of New York, referred to a case in which the patient who had pain in the hands with loss of the nails was advised to ride a bicycle. As soon as he began to ride systematically the same symptoms appeared in the feet. In this case the urine contained a trace of albumin and a few casts, but no sugar. The vessels were diseased. He is of the opinion that the vessels play an important part in the course of such affections. William Osler, of Baltimore, said that an important point in the study of these cases is to determine the relation of the pains in the extremities to the arterial disease. He had seen such combinations followed by gangrene, particularly in cases of paresthesia of the extremities in elderly women and in numbness in old men with vascular change. James J. Putnam, of Boston, said that although the diseases under discussion seem to merge, still they are fairly distinct. B. Sachs, of New York, said that he would admit that all cases of this class of diseases were not due to disease of the blood-vessels, but some of them are undoubtedly due to such changes, and some are due to disease of the nervous system. Examination of the dorsalis pedis artery in addition to the examination of the radial and the ulnar arteries often give valuable information concerning a case.

J. Stewart, of Montreal, read a paper entitled **a subcortical glioma of the lower part of the ascending frontal convolution; a contribution to the nature of the speech disturbance arising from the lesions in this situation**. The patient was a man, aged 37 years, who became mute for $\frac{1}{2}$ hour or so every day or every other day for several weeks. He had headache, twitching of the muscles of the lower half of the right side of the face, dysarthria and later anarthria. He understood what was said to him and he could read printing and writing. There was bilateral optic neuritis and weakness and paralysis of the muscles of the right upper extremity. There was tenderness on percussion over the left side of the skull. Later, dysgraphia appeared. A diagnosis of intracranial new-growth situated at the lower part of the ascending frontal convolution was made from these symptoms. The tumor was removed and recovery followed.

James J. Putnam, of Boston, read a paper entitled **personal experiences in cases of Jacksonian epilepsy with special reference to the question of treatment by operation**. The therapeutic value of operation is undoubted. Cortical excision is of somewhat more value than other varieties of operation. There are, however, some cases in which this form of operation has been followed by failure. Simple exposure of the cortex has, in some cases, been followed by satisfactory results. The objects of cortical excision are (1) to remove gross lesions; (2) to remove sources of irritation in the cortex not visible to the naked eye and (3) to remove epileptic discharge centers. The author thinks that in some instances excision serves to check the discharge of the epileptic impulse for awhile and, before the patient can recover his former habit, new

habitual impulses can be created or medication may have a chance to effect a cure. A. Jacobi, of New York, said that of all the forms of epilepsy, the Jacksonian variety is less likely to be influenced than any other. It seems that operations are less frequent in epilepsy than they were formerly. In many cases no lesion can be found when operation is undertaken and he thinks that operation is not now so promising as it was. B. Sachs, of New York, said that neurologists were becoming more conservative in advising operation in cases of epilepsy and that the Jacksonian type was the only form in which operative interference was justifiable. If operative treatment is to be instituted in a case of Jacksonian epilepsy it should be applied in the early stage of the disease. If the portion of the cortex excised presents no gross lesion microscopic examination should be made of the excised portion; then evidence of focal lesion may be found. He quoted a case in which operation had been followed by cessation of symptoms for $8\frac{1}{2}$ years. Even with this feature known, the operation was justifiable because it has allowed the patient to earn his own living during a period of $8\frac{1}{2}$ years and his life has been more pleasant to him. It is possible that ordinary medication will be able to stop his convulsive seizures now.

John K. Mitchell read for himself and Simon Flexner and David L. Edsall, of Philadelphia, a paper entitled **the chemical, clinical and physiological results of the examination of 3 cases of family periodic paralysis**. During the attacks the urine of 2 of the patients had a high degree of acidity. The authors had already determined the absence of toxicity of the urine. The ammonia output was low in the intervals of the attack as well as during the attack. The stomach contents of one patient showed anacidity and there was entire suspension of the digestive functions during the attacks. The excretion of creatinin was studied for 3 weeks in one of the patients. This substance was found to be much increased just before the attack while just after the attack its excretion returned to normal. The attacks are probably due to a metabolic disturbance possibly seated entirely in the muscles. In one of the patients potassium citrate prevented and relieved the attacks, but considerable daily use of this substance did not postpone them. Two of the patients were able to ward off an attack when they felt it coming on. James J. Putnam, of Boston, referred to a case in which the use of potassium citrate had no effect. The cases are much alike. S. J. Meltzer, of New York, said that it appeared that the involuntary muscles such as the diaphragm and those supplied by the cranial nerves were not involved. He questioned why, if the disease was due to a poison affecting the muscles, the poison should be thus selective. John K. Mitchell, of Philadelphia, said that the involuntary muscles are involved in the paralysis. A. Jacobi, of New York, said that the cases appeared to him like cases of hysteria.

F. Forchheimer, of Cincinnati, read a paper entitled **the heredity of appendicitis**. He described the genealogy of one family in which, out of 25 members, 5 had appendicitis. In a second family of 52 members, 9 had appendicitis. In a third family, of 20 members, 6 had appendicitis. A. D. Blackadder, of Montreal referred to a neurotic family in which many of the members suffered from appendicitis.

THIRTIETH CONGRESS OF THE GERMAN SURGICAL SOCIETY.

(Continued from Page 1034.)

Nils Sjöbring, of Lund, a guest of the society, read by special invitation of the society, a paper on "The Parasites of Cancer." The paper was very long and it was next to impossible to understand Sjöbring. President Czerny suggested that some of the members who had examined Sjöbring's preparation express their opinion of the same. Israel, of Berlin, declared that he could see nothing more than one can find in any tissue which is kept in unsuitable culture fluids, and nothing which one could consider ameba. Gussenbauer, of Vienna, has known the bodies demonstrated by Sjöbring for years and years, but has never been able to cultivate them. Jürgens, of Berlin, says that Sjöbring demonstrated the same bodies in the bodies of cancer, calling them the cause of sarcoma. He does not think that they deserve any more attention. Czerny asked Sjöbring from the reproach of having imposed upon the society, reminding that Sjöbring has been at the congress for years on the subject. He then stated that he had seen

"A New Method for the Reposition of a Dislocated Humerus," a modification of the well known methods of gradually increasing traction on the arm by means of weights and pulleys, until the muscles relax, etc. Hildebrand (Basel) described several cases of "The Operative Treatment of Habitual and of Old Dislocations." Payr (Graz) discussed "The Technic of Operative Reposition of Dislocations of the Hip in Adults." He considers Mikulicz's proposal to remove the trochanters a very severe operation, and only suited to cases where there is very little shortening. In the discussion Schede (Bonn) described a case of double luxation. Drehmann (Breslau) praised the method of Mikulicz because the removal of the trochanter with the muscle attachments gives a much better view of the field of operation. Rotter (Berlin) presented an interesting case of Resection of the Entire Upper Arm. The patient had a tumor of the humerus; R. resected the muscles of the upper arm and the entire humerus, and attached the remains of the capsule of the elbow to the shoulder capsule. After $\frac{3}{4}$ of a year the radialis was able to perform its function, and the patient could use the hand for many purposes. Katzenstein (Berlin) demonstrated two cases of Spina bifida occulta. In one of the patients symptoms appeared at the period of most rapid growth, and Katzenstein believed them caused by the traction of the cord of tissue which is regularly found connecting the skin and the dura mater of the cord. K. removed this cord, dissecting it from the dura mater, and the symptoms, incontinence of urine and feces disappeared. Heusner (Barmen) discussed "The Treatment of Contraction following Inflammation of the Knee Joint." In two cases he has obtained good results by changing the insertions of different muscles. Steiner (Berlin) presented a patient who had Multiple Sarcoid Angioma of the Sole of the Foot with Numerous Phleboliths. S. removed the entire sole of the foot, forming a new sole by taking large flaps from the back of the foot, covering the defect with Thiersch's transplantation. Joachimsthal (Berlin) demonstrated a number of preparations showing the conditions in congenital dislocation of the hip; also a large number of skiagraphs of the several patients whom he also presented.

Franke (Braunschweig) reports several cases of Extirpation of the Pancreas for Carcinoma. The first case showed a tumor of the head of the pancreas; he extirpated the entire organ. For 18 days the patient had diabetes, up to 3% sugar, but no stools and no other disturbances. The patient lived 6 months. Autopsy showed only metastases in the lymphglands, so that it was probably a case of primary carcinoma of the pancreas. F. mentions two further cases where he removed but a part of the pancreas, since metastases were already present. He arrived at the result that diagnosis of tumor of the pancreas has made advances. The first symptoms are extreme pain in the abdomen and rapid cachexia. He recommends an early exploratory laparotomy. Körte (Berlin) referred to two cases of extirpation of pancreas tumors. One patient died from extensive hemorrhage, the other in coma; the latter case showed diabetes, yet the autopsy showed only a part of the pancreas affected. Hildebrandt (Basel) questioned whether in Franke's case the entire pancreas was removed. Franke, although he did not perform the autopsy himself, answered in the affirmative. Ahrens (Bonn) described a case of Fetal Inclusion in the Mesocolon Ascendens. A girl of 16 came under observation with a history of having had a swelling of the abdomen while a child; she showed the symptoms of hydronephrosis, but the operation disclosed a tumor in the mesocolon ascendens. Punction gave 4 liters of a dark brown fluid found to be blood. The preparation which Ahrens demonstrated has the form of a stomach, with pylorus and cardia, and shows a microscopical structure of the stomach, except that all the different forms of epithelium were to be found. Pepsin was found in the contents. Further this extra stomach had a true peptic ulcer. Ahrens explains the curiosity by assuming that the cells, or part of the cells, destined to form the digestive tract and its outgrowths become dislocated at an early period of fetal life.

Goldmann, of Freiburg; The Pathogenesis and Treatment of the Keloid."

Goldmann believes he has found the cause of the keloid in the disappearance of the elastic fibers of the cutis, and compares the origin of the tumor to an aneurysm, due to the loss of the elastic tissue. Contrary to what others claim, he has found medullated nerve fibers in these tu-

mors. He recommends excision and closure of the defect by transplantation.

Lauenstein, of Hamburg, reported a case in which incisions which went through the cutis were followed by keloid degeneration.

Eighth Session.

The 8th session of the congress was devoted principally to the discussion of the surgical treatment of acute appendicitis. An impartial observer was forced to the conclusion that the German surgeons had reached, at the end of their discussion, the point where American surgery stood some ten years ago. Rehn, of Frankfurt a. M., believes that his results show him the only proper method to be early operation, as soon as the diagnosis is fixed. Sprengel, of Braunschweig, agrees with Rehn. Roller, of Berlin, recommended highly the recto-vaginal route for opening Douglas abscess. He claims extraordinary results. Hirschberg, of Frankfurt a. M., believes that Rehn's method of opening the abdomen as soon as possible can only be carried out in hospitals of large cities. Kummell, of Hamburg, enters the lists for conservative treatment. Of the 1042 cases in the Hamburg-Eppendorfer hospital only 1.6% ended fatally. To be sure he believes in the old principle "Ubi pus ibi evacua," with the exception of the peritoneum.

The vote for the President of the next Congress resulted in a tie between Kuster, of Marburg, and Kocher, of Bern. A second vote elected Professor Kocher.

GREAT BRITAIN.

The British Medical Association will meet at Cheltenham, England, July 30th to August 2nd, inclusive.

Appointment.—Dr. Samuel West has been appointed Joint Lecturer on the Principles and Practice of Medicine in St. Bartholomew's Hospital Medical College.

Monument to Professor Huxley.—It is proposed to erect, at the place of his birth, a memorial to Professor Huxley. The form it will take is not at present decided upon. Subscriptions to the fund may be forwarded to Mr. T. Simpson, Fennymere, Castle Bar, Ealing.

Gift to the Royal Hospital.—Alfred Harmsworth, of the *Daily Mail*, is credited with having donated £10,000 to the Royal Hospital for the purpose of installing a plant for the electric light cure of lupus.

Mr. Frederick Treves, C. B., F. R. C. S., was Knighted by his Majesty the King, on May 4th, and invested with the insignia of a Knight Commander of the Royal Victorian Order.

Dr. Lillie Saville is the first woman doctor who has received the decoration of the Red Cross during the present reign. The distinction was conferred on her on account of her services while under fire in Pekin.

CONTINENTAL EUROPE.

French Gynecological Congress.—The third meeting of the French National Periodical Congress of Gynecology, Obstetrics and Pediatrics will be held this year at Nantes under the general presidency of Dr. Sevestre, of Paris, who will also preside over the Section of Pediatrics. Dr. Segond, of Paris, will be President of the Section of Gynecology, and Professor Queirel, of Marseilles, of that of Obstetrics.

A French philanthropist.—Mlle. de Noualhier has a hobby for caring for consumptives in the last stages, found in Paris, from which city she has them taken to a villa in Limoges, not far away, to be eased in their last moments. She works only among destitute consumptives, taking them to her chateau, where they are cared for and buried at her expense. She began her work some five years ago.—*Exchange.*

New Children's Hospital.—St. Petersburg has decided to erect a new children's hospital in that city in commemoration of the coronation of the Czar. The hospital is to consist of eight pavilions, containing in all 402 beds. The estimated cost is 1,700,000 roubles.

Physicians for the Newfoundland Sealing-Fleet.—For the first time in the history of the Newfoundland sealing-fleet, says the Canadian correspondent of *The Lancet*, physicians accompanied it. The fleet numbers about six thousand sailors, and left St. John on March 9th.

2.—Montizambert describes the epidemic of small-pox that is at present affecting the inhabitants of Canada, which he believes was imported into that country from the United States. The patient, as a rule, has but little initial fever, a very sparse and discrete eruption and no secondary fever. He is usually not confined to bed and, in many cases, not even to the house, so that no physician sees the disease. In the country the disease is called chicken-pox or German measles; while in many of the lumber camps it is spoken of as "cedar itch." Those affected travel in public conveyances from one part of the country to another during the period of incubation and with the eruption in its early stages visible on their faces and thus spread the disease. [J. M. S.]

3.—In 3 series of experiments Copeman inoculated small-pox lymph or pulp directly into calves with negative results in every instance. When the same substances were inoculated into monkeys success was invariably obtained and when, after one or more passages through this animal, the contents of the local inoculation vesicles were employed for inoculation into the calf, a result was produced which, after one or more removes in that animal, was indistinguishable from typical vaccinia. Moreover, from the contents of vesicles produced in this manner on the calf a considerable number of children have, in turn, been vaccinated and afterward kept under observation for about 2 months. Every such vaccination took normally and in no case was any bad result observed. It would thus seem as though there was some relation between vaccinia and the inoculated form of small-pox in man. [J. M. S.]

4.—Barling reports the case of a man, aged 31 years, who for 4 years complained of pain and sickness after eating. Three and one-half years before his admission to the hospital, when his symptoms were of the same character, an exploratory operation with gastrojejunostomy was advised. The operation of an exploratory nature was done but was followed by no appreciable benefit. The pain following this operation was greatly increased and the patient, in consequence, took so much morphin that he developed the morphin habit. The patient was now admitted to the hospital and was operated on a second time. There was marked dilatation of the stomach but no definite obstacle to explain the condition. Dense adhesions were found, however, uniting the pylorus of the stomach to the surrounding structures. Gastrojejunostomy was done and progress for the first 4 days was satisfactory. On the fifth day the patient became suddenly worse and died of general peritonitis. At the autopsy it was found that fluid was escaping into the peritoneal cavity from a tear in the extremely dilated duodenum. The first portion of the duodenum was so dilated that it would hold about a half pint. The communication between this cavity and the stomach was free, but the opening into the second portion of the duodenum

was guarded by 3 flap-like projections of mucous membrane. The walls of the dilated duodenum were extremely thin and consisted almost entirely of thin, almost transparent, fibrous tissue. The increased difficulty of emptying this dilated portion of the duodenum, due to the establishment of communication between the stomach and the jejunum was undoubtedly the cause of the rupture. [J. M. S.]

5.—B. G. Moynihan reports an interesting case of rupture of the small intestine at the duodeno-jejunal juncture in which it was necessary to excise $4\frac{1}{2}$ inches of the jejunum and in which it was impossible after this resection to do an end-to-end anastomosis because the duodenal end was inaccessible. This end was then inverted and the jejunum united to the anterior wall of the stomach by a Murphy button. The condition of the child was such that no lateral anastomosis could be made between the duodenum and jejunum below. The patient made a good recovery. On the 104th day after the operation the child suddenly became seized with an acute abdominal pain and died within a few hours. The postmortem showed death to be due to perforation of the duodenal stump from pressure exerted by the Murphy button which had become lodged here. The case is an interesting one because it shows that for 104 days this child was in perfect health although the bile and pancreatic juice flowed into the stomach. [J. H. G.]

6.—A. C. Wilson reports an interesting case of sarcoma of the stomach which involved the greater curvature and a considerable part of the duodenum. The growth was isolated with some difficulty and was then excised with a considerable portion of the stomach and duodenum. An anastomosis was then made between the remaining portion of the stomach and bowel by means of Allingham's bobbin of decalcified bone. The patient made a good recovery and had returned to his work two weeks before this report was made. The growth was found to be a sarcoma of the mixed cell type. [J. H. G.]

7.—H. Wynter Shettle reports a case of a young girl upon whom he operated 25 hours after perforation of a gastric ulcer. At the time of the operation there was general abdominal pain and pain in the back; the abdomen was rigid and tender. The distension was moderate and liver dulness was present. Upon opening the abdomen the perforation was found to be in the anterior wall of the stomach near the lesser curvature just below the esophageal opening. The toilet of the peritoneum consisted in careful wiping with dry sponges. The patient made a satisfactory recovery. [J. H. G.]

8.—Maitland reports the case of a Hindu, aged 44 years, who complained of abdominal pain and constipation. Eight years previously, the patient began to suffer from attacks of severe pain which occurred at irregular intervals in the right side of the abdomen. The patient thought he could feel a lump at the seat of pain and stated that the condition was accompanied by constipation. When he was admitted to hospital a tumor could be felt in the right iliac region, and a diagnosis of chronic disease of the cecum or ascending colon causing thickening of the intestine and possibly stenosis was made. At operation the bowel was found to be much thickened and embedded in a mass of considerable thickness. The diseased area was excised, the end of the divided large intestine was closed and the cut end of the small intestine was united to the large intestine by a lateral anastomosis with a Murphy's button. The excised portion of the bowel consisted of ileum, cecum and ascending colon. The wall of the intestine was thickened and hypertrophied, the mucous membrane of the cecum presented an ulcerated surface and there were 5 small ulcers in the ileum. Recovery was uninterrupted. The ulcerations in the intestine were tuberculous in nature. [J. M. S.]

9.—Stevens describes a liver in which there were 2 hydatid cysts in different stages of degeneration. Both cysts were situated in the peripheral parts of the liver and projected considerably beyond its surface. There was no evidence of pus in the contents of either cyst. The capsules of both cysts were globular and tense with no signs of puckering or contraction. Neither cyst contained bile. There was a general fibrotic condition of the liver. The author believes that in the majority of cases the death of the parasite in an hydatid cyst is due to changes in and around its capsule, and that these changes are most likely to occur in organs in which fibrous overgrowths are common. The author believes that early removal of the entire cyst contents is the only rational treatment of the disease. [J. M. S.]

10.—Nuttall and Dinkelspiel have injected rabbits by the peritoneal route with horse, dog, ox, sheep and human serum and have been able to observe the formation of specific precipitins in their blood. The antisera have been tried on 24 different bloods with, with few exceptions, uniformly negative results. Bloods which have been dried for 2 months gave a positive reaction when tested with their particular antiserum. The authors conclude that these precipitins are specific although they may produce a slight reaction with the serums of allied animals. The substances in the serum which brings about the formation of a precipitin, as also the precipitin itself, are remarkably resistant. This test can be applied to a blood which has been mixed with that of another animal. The authors believe that this is the most delicate test for detecting and differentiating bloods and hope that it will be put to forensic use. [J.M.S.]

11.—Robertson describes 3 cases which seem to show that epileptics often commit criminal acts of which they are entirely unconscious and for which they are of course not responsible. [J. M. S.]

8. Medical Notes on the Life of Edward Gibbon, the Historian. WILLIAM H. HORROCKS.

1.—Abstract will appear when the lectures are concluded.

2.—Jones delivered an address before the South Eastern Division of the Medico-Psychological Association on April 24th, 1901, on the importance of the teaching of insanity to the medical student and practitioner. In Great Britain and Ireland there is on an average one insane person to every two hundred and sixty-six persons of the population. The law pertaining to insanity imposes a great responsibility upon the medical men in certification. On an average each member of the medical profession in England has issued five certificates. The author states that this duty of the physician is of far less importance when compared with the duty of prevention and treatment of insanity. He suggests that the teaching of mental disorders should be a part of the curriculum of every medical school. One of the chief reasons why the student should be familiar with the study of insanity, is that the disease can be most successfully treated in its early stages, and therefore its recognition at this time becomes most important. He also suggests that every public asylum should become a school for post-graduate teaching. [F. J. K.]

3.—Thomas H. Morse advises the use of local anesthesia in those cases of acute peritonitis, internal hemorrhage and intestinal obstruction where the patient's condition is so bad that the effect of a general anesthetic is to be feared. He reports 5 cases in which he has used local anesthesia in making an abdominal section and in three instances the patient recovered. Two of the cases which recovered were ruptured tubal pregnancies. Very little pain was complained of during the operations excepting in the cases just referred to, where dragging upon the tube produced some pain although the ligation caused none. The author thinks that pain is less acutely felt when the patient is *in extremis*. He refers to a case of strangulated umbilical hernia which died after operation under general anesthesia, due to the fact that some of the fecal vomit found its way into the air passages. [J. H. G.]

5.—Adolph Bronner discusses the diseases of the maxillary antrum. Up to the 6th or 7th year the antrum should always be opened through the middle nasal meatus and not through the alveolus. Cases of acute empyema of the antrum were rare prior to the recent epidemics of influenza. The pain in these cases is intermittent and depends greatly upon the amount of fluid in the antrum. The teeth are painful and will frequently cause the attendant to suspect that they are diseased and the cause of the empyema. These cases usually recover spontaneously. Chronic empyema is very common and the idea that this condition gives rise to distressing symptoms, such as distension of the cheek, severe pain, etc., is a mistake, the subjective symptoms being in truth very slight. Intra-orbital neuralgia, and more frequently pain over the nose and orbit, are very common. The condition is frequently mistaken for disease of the frontal sinus. A blocking of one nostril and nasal discharge and a bad smell are frequent symptoms, particularly the latter. The discharge and the smell are more marked when the patient bends the head forward or to one side. The irritation of the pus gives rise to polypi, hypertrophy of the middle turbinated, and dryness of the throat. The so-called incurable cases of ozena are usually those in which the antrum is involved. Where the cheek is distended the cause is usually a cyst and not an empyema. In these cases an opening should be made into the lower meatus with a trocar and the cavity washed out. The author does not think transillumination of great benefit. He denies the existence of "hydrops" of the antrum, these cases always being cysts. Cysts of the antrum are nearly always of dental origin caused by the retention of unerupted teeth or due to inflammatory changes in the root membrane of an already erupted tooth. Carcinoma is the most common form of neoplasm found in the antrum and its first symptoms are severe pain in the cheek and nasal discharge. Nasal polypi are frequently present and bleed freely. Removal of the entire upper jaw should be the treatment and the prognosis is fairly good. Morse says that inflammatory conditions of the antrum are rarely due to the teeth and nearly always have their origin in the nasal cavity. The treatment of empyema consists in opening the antrum at lowest point and keeping up the drainage. Morse prefers to open through the alveolus excepting in cases of polypi, large cysts, and when the teeth are all sound, when the canine fossa is preferred. The drainage should be kept up for at least 4 to 6 weeks after all discharge has ceased. [J. H. G.]

6.—Bellei writes upon mental fatigue in school children and draws conclusions upon this subject from 2760 dictations, which observations he collected in 2 months. He found that at the end of the afternoon lessons the worst results were obtained and that at 12.30 P. M., that is, just after the mid-day rest, the best results were obtained. He believes that the morning lessons do not produce great mental fatigue and that the rest at mid-day is of great benefit to the children, the mind, just after this period, being in the best condition. The application, to study, for an hour or so in the afternoon produces marked mental fatigue. [F. J. K.]

7.—Willis reports three cases of myxedema of varied type. The first case was that of a woman, 60 years of age, who presented many of the typical symptoms of myxedema, developed delusions and hallucinations after thyroid treatment had been instituted for a short while. The treatment was then discontinued but the mental excitement did not subside, and finally the patient developed acute mania. She was removed to an infirmary and died within a few weeks. The second case was that of a woman, 45 years of age, the case being of special interest on account of its very insidious onset, making the diagnosis very difficult for a time. The third case occurred in a married woman, 52 years of age, and was instructive from a diagnostic standpoint, because of its marked resemblance to Bright's disease and of its similarity to brain disease. The last two cases improved under treatment with tabloids of thyroïdin. [F. J. K.]

MEDICAL RECORD.

May 25, 1901.

1. Orchitis and Epididymitis in Typhoid Fever. FRANCIS P. KINNICUTT.
2. The Operative Treatment of Umbilical Hernia in Adults. JOSEPH A. BLAKE.
3. The Borderland of Insanity; Where and What is It? HENRY WALDO COE.
4. Recurrent Oculomotor Paralysis; Report of a Case with Remarks. WILLIAM M. LESZYNSKY.

1.—Francis P. Kinnicutt gives a history of two cases of orchitis and epididymitis occurring in typhoid fever. He believes that epididymitis or orchitis occurring in the course of the typhoid fever is a rare lesion, is of typhoid origin, and is only exceptionally due to secondary microbic infection. It develops at a late period of the disease. The lesion is as a rule unilateral. Effusion into the tunica vaginalis is rare and the termination is most often by resolution. Suppuration occurs in 25% of all cases. Localized necrosis and extrusion of testicular tissue is not uncommon, exceptionally there is obstruction of the entire organ, and atrophy of the testicle may occur. The lesion gives rise to very little constitutional disturbance and death from the lesion has not been noted. [T. L. C.]

2.—Joseph A. Blake discusses the operative treatment of umbilical hernia in adults, after first reviewing the pathology of umbilical hernia, and its palliative treatment. Umbilical herniae are divided into two classes,—those in which there is no separation of the recti muscles and those in which these muscles are separated. Lack of muscular tone and fat, by diminishing the contractile power of the recti muscles, tend to the production of this form of hernia in adults. The stretching is not confined to the linea alba but the sheaths of the muscles also participate in the process. Blake thinks that strangulation in umbilical hernia is more frequent than is generally supposed and that when it does occur the prognosis is more grave than in either inguinal or femoral hernia. The results from operation, particularly in large herniae, have not been very satisfactory. The smaller the hernia the better the chance of a radical cure. The condition of the contents will greatly influence the diagnosis. The various methods of radical cure are discussed and the one of lapping the abdominal wall is preferred by the author; he reports three cases operated upon in this way. This method is particularly applicable to the cases in which there is a separation of the recti muscles. It consists in the overlapping of the entire abdominal wall on one side by that on the other. [J.G.H.]

3.—Henry W. Coe discusses the borderland of insanity. His paper in the main is taken up with the sexual phase of the subject. He deplores the erroneous belief that sexual expenditures are necessary for the maintenance of good health, and believes that this fallacy has had much to do with the encouragement of sexual excesses and the consequent prevalence of the class of cases discussed. [T. L. C.]

4.—William M. Leszynsky reports a case of recurrent oculomotor paralysis occurring in a woman 29 years of age and a type-setter by occupation. When 12 years of age the usual paroxysms and ptosis of the right eye occurred, recovery taking place in two weeks. The second attack of oculomotor paralysis occurred in her 19th year, and the third attack in her 22nd year. A fourth attack occurred when she was 27 years of age and the fifth attack three weeks before the patient was seen by the author. Examination at this time showed slight drooping of the right upper eyelid, paralysis of the superior rectus muscle and paresis of the inferior and internal recti muscles. There was no diplopia, as the image of the right eye was suppressed. The excursions of the external ocular muscles of the left eye were normal. The author calls attention to the comparative rarity of this variety of oculomotor palsy and its pathology. He refers to the two authentic cases that have been studied postmortem. Electrical treatment in this case caused recovery in three weeks. [M. R. D.]

NEW YORK MEDICAL JOURNAL.

May 25, 1901. (Vol. LXXVIII, No. 21.)

1. Hyperacidity (Superacidity, Hyperchlorhydria, Superaciditas Chlorhydrica); a Clinical Study. H. ILLOWAY.
2. Nasal Condition observed in the Aged. BEAMAN DOUGLASS.

3. What Route shall we Adopt in Examining the Eye Muscles? ALEXANDER DUANE.
4. Ossiculectomy for Chronic Suppurative Otitis Media. J. A. STUCKY.
5. The Importance of the Early Recognition of Abdominal Infections. W. D. HAMILTON.
6. Antistreptococcus Serum in two cases of Puerperal Septic Infection. A. J. PRIMROSE.

2.—Douglass tries to explain why fewer old people complain of nasal catarrh than do younger or middle-aged people, in the following manner: (1) The physiological activity of the nose has been increased so as to overcome the damage from the lesions; (2) That the lesion, with its resulting discharge and reflex pain, is in some way less active, and allows the nose to resume its physiological functions. It is possible that as the system grows older elimination is decreased and there is less demand on the part of the inspired air for heat and moisture to satisfy the physiological function of the respiratory tract. The symptoms of pain, together with those of reflex phenomena, he thinks, depends not so much on the quantity of inflammation or upon the degree of circulatory disturbance and lymphatic obstruction as upon a certain condition of the nervous structures that are distributed through the nares. [T. M. T.]

3.—Duane gives the diagnosis between habitual binocular fixation, an alternating fixation and a uniocular squint as follows: (1) If in binocular uncovering *but one eye moves*, we have heterophoria and not squint; (2) If either *both eyes move* or, in spite of there being an evident deviation, *both eyes remain steady*, there is a squint; (3) In the latter case, if, when the left eye is uncovered, the eyes behave in the same way as they do when the right eye is uncovered (both alike moving or both alike remaining steady, no matter which eye is uncovered, the squint is *alternating*; (4) If, when one eye (for instance, the right) is uncovered, both eyes move, and when the other eye (in this case the left) is uncovered, both eyes remain steady, the squint is *uniocular* (confined in this case to the left eye). [T. M. T.]

4.—Stucky recommends in cases of chronic suppurative otitis media which have existed for a long time, the removal of the necrotic ossicles and part or all of the tympanic membrane and the cavity thoroughly curetted. He also removes the anterior attic wall which will give free drainage and open the way for remedial applications. He gives the advantages of this method as follows: (1) It gives free drainage; (2) It affords an opportunity to successfully combat the suppurative process; (3) It is free from danger to life and health; (4) In a large percentage of cases the disease is arrested, the hearing improved, only rarely made worse; (5) There is no deformity or scar. He does not believe in dry treatment of this disease, as it is inadequate because of the debris collecting around the ossicles and thinks conservative surgery is justified because this hindrance is removed. [T. M. T.]

MEDICAL NEWS.

3. The Treatment of Chronic Purulent Otitis Media. JAMES F. MCKERNON.
4. Tuberculosis of the Iris. WILLIAM F. ...

4.—Mittendorf states that tuberculosis iritis may start in the iris itself or in the ciliary body and the choroid. It spreads very soon from one to the other involving the entire eyeball, or at least its inner parts. It is usually a secondary affection, but sometimes primary. The author divides it into (1) The solitary form, and (2) Multiple form. The multiple he also divides into acute and chronic. It is generally a disease of the young or early middle life and only affects one eye, differing from tuber-

culous affections of the choroid, which attacks both eyes at the same time. In the solitary form the disease assumes a more or less acute stage at once, characterized by the formation of one or more grayish nodules developing on the iris tissue. It consists of inflammatory products with a small number of bacilli and is marked by the early appearance of ciliary infection and is accompanied by intense pain in the eye and forehead. The pain is sometimes so great that enucleation of the eye becomes necessary. In this form there is impairment of vision or destruction of the entire eyeball and not infrequently death, which is brought about by similar simultaneous attacks of the meninges or lungs, or by direct extension of the disease to the brain. The multiple form is not so violent in its onset and there are not so many bacilli present in the deposits. This occurs generally in the earlier stages of pulmonary tuberculosis. We find in the iris this form more than one or two tubercular deposits. There are also pain and photophobia and more or less invasion of the pupillary border of the iris, which in turn leads to the formation of the posterior synechiae. This form runs a much slower course and iritis may be relieved entirely if the general condition of the patient improves, or it may result in occlusion of the pupil with eventual shrinking of the eyeball. [T. M. T.]

BOSTON MEDICAL AND SURGICAL JOURNAL.

May 23, 1901.

1. Municipal Care of the Consumptive Poor. S. A. KNOPF.

1.—In an address before the clinical section of the Suffolk District Medical Society, Knopf emphasized the fact that **pulmonary tuberculosis** is a curable disease as well as a preventable one, provided it is diagnosed early. The mortality from tuberculosis is most frequent between the ages of 17 and 35, just at a period when the individual should be a most useful member of society, a breadwinner and, if possible, a supporter of a family. This is a great economic loss to the community as well as a calamity to the family of which the afflicted person is a member. The most essential requirements for the treatment of a consumptive are good pure air and plenty of it, sunshine and plenty of it, medical supervision and plenty of it. A city tenement house is not a place in which these conditions prevail. Sanatorium treatment, besides including the administration of drugs, teaches the patient to control his cough, except when he has to expectorate; to be rigorously clean and careful with his expectoration and other secretions; how not to take cold; what to do in case of accident; what to avoid and what to do in order to continue on the road to recovery. The regular life that he leads and the hygienic training that he receives are of inestimable value to the patient as well as to his family. One objection to the establishment of a sanatorium for consumptives comes from property holders in the neighborhood, who believe that the disease will spread and that the value of their property will decrease. It can be proved by official statistics that the mortality from tuberculosis in 2 German villages where consumptive sanatoria now exist has been reduced one-third since the establishment of these institutions. An instance was also cited in which the establishment of a sanatorium for the treatment of tuberculosis resulted in an increase in the value of the adjoining property. Each city should have an especially constructed building that should serve as a reception hospital for tuberculous patients whence cases for the city hospital or state sanatorium should be selected. A sanatorium should be established near the seashore for the treatment of tuberculous and scrofulous children. The managers of maternity hospitals should set apart the best-lighted and best-ventilated wards and rooms for the exclusive treatment of tuberculous pregnant women. A tuberculosis commission should be formed composed of physicians and laymen. The duties of this commission should be (1) to determine the applicant's condition by a medical examination and

to assign him to the proper hospital or dispensary for treatment; (2) to visit the home of the patient and to institute such hygienic measures as seem necessary to prevent further contamination; (3) to examine the other members of the family in order to determine whether any of them have contracted the disease and to counsel proper treatment; (4) to make full report to the sanitary authorities as to the condition of the patient's dwelling; (5) to distribute literature and to give advice concerning the prevention of tuberculosis and hygiene in general; (6) to determine the financial condition of the applicant for treatment and the condition of other members of the family if it is the father who is removed. [J. M. S.]

8. Tubercular Disease of the Knee-Joint and Hip-Joint in Children. Diagnosis and Treatment. EDWARD A. TRACY.
9. Cough Due to Reflex Irritation in the Upper Air-Passages. FRANK S. MILBURY.

1.—Wells gives an account of the pathology of active tuberculosis of the pericardium and reports ten cases. Three of these cases were of the chronic miliary variety accompanied by fibrous adhesions. In three there was an acute miliary eruption accompanied by a serous or bloody fluid, mixed with fibrin, in the pericardial sac. In three cases caseous masses and fibrous synechia were found, and in one case acute inflammation of the pericardium was present, without tuberculous lesions, due to tuberculous toxin. A general tuberculosis, of the lungs and of the abdominal viscera, was found in this case. Wells states that the bacilli may be carried to the pericardium with the lymph stream, this being the most common manner in which infection takes place; or the bacilli may gain entrance through the blood stream or by extension—from the mediastinal glands, the pleura, the myocardium, and the vertebrae. As a rule, tuberculous pericarditis terminates in death, but it is possible for healing to occur. Commonly death, in cases of tuberculosis of the pericardium, is not due to causes relating to the heart, but results from tuberculosis of some other part of the body. Rarely is tuberculosis pericarditis recognized during life as the condition is generally unaccompanied by symptoms referable to the heart. [F.J.K.]

2.—Stewart discusses tuberculosis of fascia and concludes that this condition occurs with sufficient frequency to entitle it to more general attention. He recognizes two varieties, (1) primary acute cases, the most important feature of these being an extensive cheesy degeneration; (2) chronic cases, which are, as a rule, secondary, accompanied by hyperplasia of connective tissue with disseminated areas of caseation. He maintains that it is essential to distinguish these forms in order to properly institute surgical treatment. Inoculation experiments may be necessary to demonstrate the tuberculous character of the fibrous tissue, and he believes that the fibrous tissue resulting from tuberculous infections should be regarded as tuberculous tissue, and therefore should be treated accordingly. [F.J.K.]

3.—Boyd reports a case of sarcoma of the pancreas which occurred in a male, 47 years of age. The patient was admitted to the Policlinic Hospital, Chicago, on November 16, 1898. His family and previous personal history did not throw any light upon his condition. The patient noticed a lump in his abdomen and complained of a pain in that region in June 1898. An exploratory laparotomy was made on November 23d by Dr. Harris. It was found that the case was inoperable, so further procedure was aban-

done. The patient died a short time after the operation. A complete autopsy was not performed, however, the abdomen was opened and the tumor removed, which, upon microscopical examination, proved to be a sarcoma. [F. J. K.]

4.—Lieberthal gives an account of a case of epithelioma developed on the basis of a healed lupus vulgaris. The patient developed lupus when two years of age and suffered from this condition until he was 12, then for a period of 38 years he enjoyed comparatively good health. About 8 months ago a painful nodule appeared on the left side of the lower jaw. This mass increased in size very rapidly; the diagnosis of epithelioma of the face was confirmed by microscopic examination of the tumor. The application of the X-Ray was suggested, and it appears that the growth of the neoplasm was not checked. The mass had flattened somewhat but it spread towards the chin about an inch. [F. J. K.]

5.—Jacob Frank discusses ureteral implantation into the bowel which he thinks should never be an operation of choice but only one of necessity. It is preferable to nephrectomy, and is justifiable in certain cases of cancer of the bladder in which the outlets of the ureters are encroached upon. Unilateral implantation is indicated where the ureter is wounded high up in case an anastomosis or repair cannot be made. The author reports 10 experiments which he has performed on dogs. The technic of the operation is minutely described and illustrated. An incision is made longitudinally through the peritoneal coat which is then loosened and retracted. The muscular and mucous coats are then divided longitudinally, the ureters inserted and fixed to the mucous membrane below this incision, which is then closed transversely. The transverse closing of this longitudinal incision tends to lessen any compression of the ureter. The peritoneal coat is then sutured. This method prevents any possible infection of the peritoneal coat by means of the sutures, as those entering the bowel are entirely enclosed below the peritoneal coat. In a large majority of dogs operated upon inflammatory changes in the kidneys took place. [J. H. G.]

6.—Chevalier Jackson thinks that a much overlooked nasal factor in ear diseases consists in the hypertrophic thickening which takes place at the posterior margin of the vomer and which results in a deflection of the inspired air against the Eustachian eminences. The author has found this hypertrophy of the vomer to be present in 25% of his private ear cases and in 11% of his nose and throat dispensary patients. Operations are frequently done upon the inferior turbinals when the real cause of the trouble lies in the vomer. It is urged that where this hypertrophy exists with ear disease that it should be completely removed and that wherever it is found alone it should be removed in order to prevent subsequent ear disease. In relieving stenosis it is a mistake in removing the posterior turbinal hypertrophy to take away so much as to expose the Eustachian eminence to the direct blast of the inspiratory current. [J. H. G.]

8.—Edward A. Tracy urges upon the general practitioner the great necessity of being able to diagnose early tubercular lesions of the joints, since the early institution of treatment has so great an influence upon the prognosis. Since slight injuries of the knee-joint in individuals with a tubercular tendency are so apt to give rise to serious trouble, the family history and predisposition of the patient should always be carefully inquired into in case of injury to joints. The chief diagnostic signs of tubercular knee-joint diseases are limitation of motion, enlargement of joint measurements, tenderness on pressure and muscular spasm elicited by attempting passive motion. In acute cases heat is often present. The treatment of this condition consists in immediate fixation of the joint and rest, together with the proper hygienic and constitutional treatment. The author thinks that plaster-of-paris is an ineffectual method of producing fixation and recommends instead the wood-plastic material. This should be moistened and applied next to the skin. As improvement takes place the patient should be gotten out of bed and, if over six years of age, should be made to use crutches, but if younger than this a Thomas splint should be applied. The early symptom of tubercular hip-joint disease is limitation of the normal motions of the joint together with the usual well-known symptoms, such as pain and limp. The principle of the treatment here is the same as in diseases of the knee-joint, fixation and rest, and here again the wood-plastic material

is recommended after any flexion of the thigh which may be present, has been overcome. [J. H. G.]

9.—Milbury maintains that when cough is spasmodic or when cough is unaccompanied by physical signs of pulmonary disease, or when cough persistently resists all medication for permanent relief, it is of reflex origin. He further states that when there is comparatively little disturbance of the general health, and when upon removal of the cause the cough ceases, it should also be regarded reflex in origin. [F. J. K.]

AMERICAN MEDICINE.

7. Blood Examinations as an Aid to Surgical Diagnosis. JOSEPH C. BLOODGOOD.
8. Fractures and Dislocations of the Spine. STEPHEN H. WEEKS.

1.—Will be abstracted when concluded.

4.—Victor C. Vaughan has found in his work on the bacteriology of cheese that the colon bacillus is present in practically all samples of American green cheese, and has determined that cultures of this germ may be boiled without destroying its toxicity. The facts that he has learned may be summed up as follows: The toxin is not contained within the germ-cell from which it does not, at least under ordinary conditions, diffuse into the culture media. The toxin is not extracted from the cell by either alcohol or ether. Very dilute alkali do not extract the toxins from the cells. The germ substance may be heated to a high temperature with water without destruction of the toxin. Boiling with a 2% solution of hydrochloric acid, has but little if any effect upon the germ cell or its contained toxin. The toxin as separated from the cell wall by digestion of the latter with HCl and pepsin is markedly active.

[T. L. C.]

5.—R. C. Rosenberger makes a plea for uniformity of technic in the Widal reaction. He emphasizes the following points: (1) The use of a uniform dilution. (2) A definite time limit. (3) An agreement as to what constitutes a positive reaction. (4) The use of a culture of definite age and a clear statement as to incubation or non-incubation. (5) A decision as to whether dry blood, fresh blood or serum is to be used. (6) A stated number of tests to be made in a given case. (7) To drop the terms "doubtful" and "pseudo-reaction," and (8) To use the terms "positive" and "negative" only. [T. L. C.]

7.—Joseph C. Bloodgood presents the abstract of his paper on blood examinations as an aid to surgical diagnosis. Observations have shown that there is a leukocytosis of 15,000 to 24,000 following hemorrhage. There is also a diminution of the red blood cells and the hemoglobin. In severe hemorrhage the blood count will indicate to a certain extent the amount of blood lost, but not usually until 6 to 10 hours after the hemorrhage. Less than 30% of hemoglobin is regarded by most surgeons as a contra-indication to operation. He mentions the importance of the study of post operative leukocytosis, and mentions the increase of white blood cells in the first 24 to 48 hours after laparotomy between benign abdominal distension and obstruction or peritonitis. In appendicitis there are usually valuable indications to be derived from the study of white blood cells. Cases of the recurrent variety there is rarely an increase. In a few instances when the case is first observed within 48 hours after the beginning of the attack when the symptoms have subsided, there have been a few leukocyte counts of 11,000 which have rapidly fallen to 10,000 and 7,000. The rapid rise of the leukocyte count is

an important indication for the necessity of operation. The record of leukocyte counts in subacute appendicitis and the differentiation between abscess and peritonitis is discussed as well as leukocytosis occurring in intestinal obstruction. [T. L. C.]

8.—Stephen H. Weeks reports a case of a patient aged 70 who sustained a fall from a ladder and who presented on examination a deformity of the cervical spine at about the fourth or fifth vertebra. A laminectomy was performed. The laminae of the fourth and fifth cervical vertebra were found broken and depressed. The patient made a good recovery and in 5 weeks was able to sit up in a chair. The author believes that the surgeon should perform an experimental laminectomy in every case if the condition of the patient is such as to justify operation. Drainage is usually required for two or three days. The spine is best supported during the healing process by plaster of Paris dressing or by sand bags placed on each side of the patient. [T. L. C.]

2.—Riesman reports a case of intermittent claudication, a condition first described by Charcot in 1858. The symptoms of the condition in general are a sensation of pain and numbness in the legs shortly after the patient starts to walk, the walking becomes impossible. After a short rest locomotion can be resumed only to be again interrupted as at first. The patient thus becomes intermittently limping. Sensation is usually normal, objectively; subjectively the patient often experiences various paresthesias. Gangrene is of common occurrence (in seven out of twenty-four cases reported by Goldflam). The majority of patients are men. The etiology of the disease coincides with that of arteriosclerosis. Syphilis, alcohol, exposure and tobacco, and perhaps diabetes, play a role. In Riesman's case examination of the arteries of the feet showed that pulsation was entirely absent in both dorsales pedes. There was shortness of breath on exertion, transient aphasia and gastric symptoms. As to treatment, Riesman's case was benefited by the iodides and nitroglycerin. The alkaline mineral waters are helpful. The patient should avoid fatigue and protect himself carefully from cold and dampness. [T. L. C.]

5.—J. A. MacGregor reports a case of peripheral venous thrombosis occurring in cardiac disease. Six weeks before death there appeared the evidences of thrombosis of the left axillary, subclavian and internal jugular veins. The onset was marked by pain and swelling and there was tenderness over the vessels. Edema of the lungs caused death. An autopsy was not performed. The patient was a sufferer from mitral stenosis and the thrombosis appeared during broken compensation. The length of life of the patient in this condition must have been attributable to the establishment of a sufficient collateral circulation. Twitching of the arm and leg was noticed several hours before death, and may have been caused by the jugular thrombosis. [T. L. C.]

6.—Heinrich Stern has investigated the question as to whether the gouty and kindred phenomena may disappear after vaccination. He reports two experimental inoculations. The gouty pains disappeared in both instances. And he mentions that the same may stand as the foundation of many affections which are clinically regarded as gout, rheumatism and neuralgia. Since vaccine lymph hardly possesses solvent or specific eliminating properties he regards the reaction as secondary or indirect. [T. L. C.]

7.—Smith records a case of pregnancy complicated by

fibroid tumor in which a Cesarean section was performed at the eighth month followed by hysterectomy by Baer's method. The patient died from heart failure, the result of an old endocarditis. [W. A. N. D.]

THE JOURNAL OF NERVOUS AND MENTAL DISEASE.

May, 1901. [Vol. 28. No. 5.]

1. A Study of the Cases of Tabes Dorsalis in Prof. M. Allen Starr's Clinic, Columbia University, from January, 1888, to January, 1901. A. B. BONAR.
2. The Scapulo-Humeral Reflex of von Bechterew. WILLIAM PICKETT.
3. Psychical Form of Epileptic Equivalent. CHARLES CARY and J. ULLMAN.
4. Cases Illustrating the Differential Diagnosis of Cerebral and Hysterical Hemianesthesia. CHARLES K. MILLS and THEO. H. WEISENBERG.

1.—Bonar in his study of a large number of cases of tabes dorsalis gives the following symptoms with the percentage of each: Loss of knee-jerks, 92.5; Changes in knee-jerks, 3.69; Romberg symptom, 79.02; Change in pupillary reaction, 78.67; Pains in the legs, 78.67; Ataxia in legs, 70.62; Vesical disturbance, 62.23; Paresthesia and numbness, 54.54; Girdle sensation, 48.6; Loss of muscular sense, 28.32; Crises, 16.78; Pains in trunk, 12.93; Optic nerve atrophy, 8.74; Ataxia in arms, 7.69; Pains in arms, 6.99; Loss or diminution of sexual instinct, 6; Pains in thighs, 4.89; Ocular paralyses (strabismus, diplopia, etc.), 3.21; Nystagmus, 2.44; Arthropathies, 2.09; Constriction around legs or thighs, 1.74; Tremors, 1.74; Perforating ulcers of foot, 1.39; Muscular atrophy, 1.39; Anosmia, 1.04; Deafness, 0.69; Vertigo, 0.34; Loss of taste, 0.34. [T. M. T.]

2.—Prickett describes the scapulo-humeral reflex of von Bechterew as one elicited by the percussion hammer along the entire inner edge of the shoulder blade beneath its inner angle—most markedly at the inner edge of the inferior angle. It consists in adduction of the corresponding humerus toward the trunk, often also in slight outward rotation, mainly produced by contraction of the infraspinatus muscle, and apparently of the teres minor. According to von Bechterew it is influenced in the following conditions: It is absent in poliomyelitis, in the spinal form of progressive muscular atrophy, in neuritis when the shoulder girdle muscles are affected; diminished or absent in muscular dystrophy and in "rigidity of the spinal column." It is exaggerated in cerebral hemiparesis or hemiplegia, especially when there is marked atrophy of the shoulder girdle muscles. Thus in determining whether such atrophy be of spinal, neuritic, or cerebral origin in a given case, the state of the scapulo-humeral reflex is significant. [T. M. T.]

5. A Practical Application in Abdominal Surgery of Scientific Investigations on the Function, Anatomy and Pathology of the Peritoneum. JOHN G. CLARK.
6. A Series of Twelve Articles on Medical Men Prominent in Civil and Military Affairs of Revolutionary Times. FRANCIS R. BACKARD.

1.—Clarke describes a new method of percussion for the detection of cystic or loculated fluids in the abdomen. It is a trimanual method consisting in the usual bimanual examination of the pelvic mass while the percussion is performed by an assistant. In this way the intestines inter-

vening between the anterior abdominal wall and the tumor are excluded. He describes an illustrative case. [W. A. N. D.]

2.—Clark has made a study of the recent statistics on the primary and ultimate results of hysterectomy for cancer of the uterus. He remarks that he is forced to confess that these statistics show that the operative treatment has not yielded as satisfactory results as has been anticipated. The great majority of cases operated upon have died within six years from the recurrence of the disease. The adenocarcinoma of the body of the uterus gives the best results if the operation be performed at a very early stage. In cancer of the fundus there is no recurrence in these cases. Winter's statistics show that the immediate mortality following operations for cancer of the uterus varies between 5.7% and 10.8%. From his review of 308 cases he reaches the conclusion that vaginal hysterectomy cannot be considered a radical means of cure, and also that the indications for operation, cannot be further extended. Schuchardt's operation, according to Clark, has not and will not have an extensive acceptance among surgeons for obvious reasons. If vaginal hysterectomy is the operation of election, the clamp method is to be preferred to the ligature method, first, when it is necessary to rapidly complete the operation, and, secondly, when it is difficult or impossible to place ligatures on account of the dense fixation of the uterus. Winter's final conclusion with regard to inoculation-growths are as follows: 1, the inoculation and growth of cancerous tissues into fresh wounds may be accepted as an established fact; 2, this factor unquestionably plays a rôle in the local recurrences after cancer operation; 3, on account of the lack of statistics it is impossible to state the frequency of these recurrences, but unquestionably a simple continuance of the local growth is much more frequent than inoculation-growths. Clark remarks that the ordinary clinical diagnosis of these cases is extremely difficult and in many instances impossible, and only through a careful microscopical examination of curettings can be definite decision be reached. [W. A. N. D.]

3.—Anspach reports two cases of endometritis closely simulating cancer of the fundus in order to emphasize the fact that the microscope as a means of exclusion is quite as valuable as in the positive diagnosis of cancer. He claims that the microscopic examinations of uterine scrapings in cases of suspected carcinoma may be of value in differential diagnosis either as a positive or negative factor. It is positive when the examination shows without question the presence of cancer; it is of just as great value when it as certainly reveals the benign nature of a pathological process which has given rise to symptoms characteristic of cancer. [W. A. N. D.]

4.—Clark remarks that of the malignant tumors of the uterus cancer is by far more frequent than sarcoma. Cancer of the uterus most frequently arises from the cervix, and seldom in the fundus. Sarcoma on the other hand rarely arises in the cervix but almost always from the fundus. This peculiarity in relationship of the two growths, as to the part of the uterus from which they spring, has been offered in support of the hypothesis that sarcomata of this organ most frequently are malignant transformations of myofibromata. The fact that a tumor had appeared in the inguinal region subsequent to the uterine growth in the case that Clark reports of sarcoma of the uterus confused very decidedly the diagnosis, for sarcoma seldom, if ever, gives metastasis to the inguinal glands, whereas this is not infrequent in cancer of the fundus. Sarcomas arise either from the endometrium or from the uterine wall. The endometrial variety is much more frequent. Gessner has formulated the following law concerning the origin of these new growths: round-cell, and a majority of the spindle-cell sarcomata, spring from connective tissue. A small proportion of the latter, however, may be transformed from muscle-cell. The points of interest in a case reported by Clark are: 1, a history significant of myoma uteri; 2, the consistence and appear-

ance of the tumor that of sarcoma, although the later occurrence of the tumor of the inguinal canal was significant of cancer of the uterus; 3, confirmation of the clinical diagnosis as to sarcoma of the uterus, and correction of the diagnosis as to malignant tumor of the inguinal glands by microscopic examination; 4, the coincidence of two rare pathological conditions, sarcoma of the fundus and fibroma of the inguinal canal, most probably of the round ligament. [W. A. N. D.]

5.—Clark reports unique pathological changes in two cases of uterus *bicornis unicollis*—(1) unilateral pyometra and pyosalpinx; (2) myoma. He remarks that in view of the peculiar development of the uterus through fusion of the lower segments of the two Müllerian ducts to form one common uterine cavity, it is surprising that malformations are so infrequent, especially when animals in the higher evolutionary scale, such as the cat, dog, pig, cow, etc., all have bicornate uteri. [W. A. N. D.]

6.—Clark makes the study of the investigations during the last six years of various scientists upon the functions and anatomy of the peritoneum. In 1896 as a result of the combined study of 1700 abdominal section cases, and the review of the literature bearing upon the structure and function of the peritoneum, he took radical ground against abdominal drainage as then generally employed and advocated certain measures which were in direct opposition to principals then generally in vogue. He favored the thorough irrigation of the peritoneal cavity, at the completion of an abdominal operation to remove as far as possible all debris, blood and infectious matter, and then the leaving of a considerable quantity of salt solution (0.6%) in the peritoneal cavity to disseminate and promote rapid absorption. He reviews the experiments of Wallgren and gives the latter's conclusions. Based upon practical experience in a large series of abdominal sections, and sustained by his own and the scientific investigations of others, he believes that the thorough irrigation with normal solution of the peritoneal cavity after abdominal operation for the purpose of removing all possible debris or infectious matter and then leaving large quantities of salt solution is the most effective preventive measure we have against post-operative peritonitis. [W. A. N. D.]

1.—In a careful review of the literature, Paul and Sarwey call attention to the various modifications of the solutions of corrosive sublimate that have been designed to render it more efficient, that is to say, to increase the quantity of mercury in the solution, which is of course the only effective agent. The more complex the molecule of which the mercury forms a part, the less is its mercuric power, and the same is true of the various preparations containing silver. Much depends upon the solvent for instance nitrate of silver in 50% alcohol manifests its maximum effect. In the discussion of the methods employed to render the mercury harmless, they have experimented with Geppert's solution of hydrogen sulphide in liquor ammoniae. It was found that if the sublimate solution was allowed to act for six minutes that the number of spores capable of developing depended directly upon the percentage of ammonium sulphide employed. This method,

therefore, diminishes the bactericidal effect of the anti-septic. The authors do not approve of artificial disinfection of the hands before performing the experiments. They do not agree with Kroenig that sterilization of the hands is complete when they are no longer capable of infecting the body, but insists that we should discover some method which renders the site of operation, provided it is not previously infected, absolutely free of germs, in order that when it heals it will act just as a subcutaneous injury. [J. S.]

2.—Kuhn has experimented upon 11 cases of various forms of pulmonary tuberculosis with hypodermic injections of *Haetol*, that is, sodium cinnamate. It does not seem clear just how this acts, for it appears unlikely that it is due to the leukocytosis produced by the injection. At any rate, it is entirely harmless, and in a small number of cases a certain amount of improvement could be observed. As, however, the usual forms of hygienic treatment were employed, this improvement can be ascribed as well to them as to the injections. In one of the 4 cases that died an autopsy was performed, and considerable induration of the pulmonary tissue discovered. This, however, is not an uncommon phenomenon. [J. S.]

3.—Nusch reports his experience gained in Neukirch's clinic with heroin and aspirin. Heroin, or triacetate of morphia, is considerably less poisonous than morphia or cocaine. It may be given with considerable safety in doses of one-twelfth to one-sixth gr. (.005 to .01). It quiets cough, increases the depth of respiration, and in large doses often causes the patients to sleep, although it has no direct hypnotic action. Apparently it does not quiet pain. It is particularly useful in tuberculosis of the larynx. Aspirin does not appear to have the objectionable effects of salicylic acid, and rarely produces tinnitus or headache. It is particularly effective in cases of acute and chronic rheumatism, and seems to have a considerable antipyretic action, even in such severe cases as pulmonary tuberculosis. The dose is 15 grs. (1.0) from 5 to 2 times daily in acute cases, or 4 times daily in the more chronic cases. It is also useful in neuralgias. [J. S.]

4.—Niessen, as regimental surgeon, has had opportunities of treating 236 cases of gonorrhea in the course of one year. He used solutions of protargol, $\frac{1}{2}\%$ in strength for the first 2 weeks, increasing gradually if the secretion persisted. Ninety-nine of these cases had their first attack, and from these he deduces his statistics. The time required to obtain a cure ranged from 5 to 43 days. In 34 of these cases there were complications. Comparing his series of 670 cases treated during 1896, he found that the average duration of the attack was no better with protargol than with other methods of treatment. Its advantage is that it is rather less painful. [J. S.]

5.—Schlesinger describes a modification of Lorentz' method of reducing congenital dislocation of the hip. If the first attempt fails the limb is placed in the position for reposition, and fixed by means of a plaster bandage for 3 or 4 days. In the first day there is usually considerable pain. Reduction is then again attempted, and in the great majority of cases is accomplished with extraordinary ease. In one case it occurred whilst the bandage was in position. If, however, it cannot be accomplished, the plaster cast is applied, and in all cases hitherto treated, the third attempt has been successful. He reports 5 cases ranging in age from 6 to 13 years. [J. S.]

6.—Simon reports the case of a woman 29 years of age, who, 8 days after delivery had diarrhea and vomiting followed by chills and severe pain in the abdomen. This was followed by all the symptoms of intestinal obstruction. Accordingly an injection of one-sixtieth grain of atropine was given, followed by three others the next day. The pulse became slower and the general condition of the patient improved, but there was no movement of the bowels. Accordingly, on the third day one-thirtieth grain of atropin was injected, repeated in 6 hours, and the following morning there was a liquid movement of the bowels, followed by diarrhea and complete recovery. The patient was slightly delirious after the large injections. [J. S.]

7.—Hochtlen reports the case of a woman 71 years of age, who had had attacks of appendicitis and peritonitis. She had severe constipation, followed in 4 days by vomiting and distension of the abdomen. As the symptoms were

not relieved by a large enemata one-twentieth grain of sulphate of atropin was administered on the 7th day. There was some delirium, and the patient complained of dryness in the throat. A subsequent injection was therefore not made, but the patient was from time to time given an enema and morphin. She finally died in collapse. At the autopsy it was found that the transverse colon was occluded by firm peritoneal adhesions, and the case was one that manifestly could be helped only by an operation. [J. S.]

8.—Schulze recommends a salve containing camphor, composed according to the following formula, for leg ulcers:

Camphor. 2 parts
Oxide of zinc. 15 to 20 parts
Lard q. s. ad 100 parts

In some cases where this is too stimulating he employs the following formula:

Camphor. 2 parts
Olive Oil. 50 parts
Zinc oxide. 40 to 50 parts

Cloths are soaked in this and laid over the ulcer. Application is to be made 2 or 3 times every day. The patients necessarily must keep still. [J. S.]

SCOTTISH MEDICAL AND SURGICAL JOURNAL.

March, 1901. (Vol. VIII, No. 3.)

1. The Edinburgh Hospital in South Africa and its Work. FRANCIS D. BOYD and GEORGE L. CHIENE.
2. Gastric Hemorrhage and Its Surgical Treatment. A. W. MAYO ROBSON.
3. A Case of Acute Cellulitis Treated by Antistreptococcic serum. FRANCIS KELLY.
4. A Plea for the More General Use of Ether as an Anesthetic in General Surgery. THOMAS D. LUKE.

2.—Robson in his article urges the following treatment in gastric ulcer: (1) All cases of acute uncomplicated gastric ulcer should be submitted to thorough medical treatment in the shape of long-continued rest and attention to diet, the cases not being allowed to get up or to resume solid food until at least a fortnight after all disappearance of pain; (2) Where the ulceration persists and proves intractable to medical treatment, or where relapses occur, gastro-enterotomy should be performed, so as to secure physiological rest and relieve the hyperacidity of the gastric juice nearly always found in such cases; (3) Perforation demands immediate surgical treatment; (4) The complications of disabling adhesions around the stomach and pylorus, pyloric contraction and hour-glass contraction due to chronic ulcers leading to pain, dilatation, loss of flesh and general impairment of health, and now often treated as chronic indigestion, should always be treated surgically; (5) In recurring, or so-called chronic hematemesis from gastric ulcer, surgical treatment is decidedly called for; (6) In acute hematemesis, further accuracy in diagnosis as to the size of the bleeding vessels is urgently needed; and the co-operation of the physician and surgeon is advisable in all cases of hematemesis, so that if relief be not obtained by medical and general treatment, surgical means may be adopted if the bleeding is believed to occur from a large vessel; but seeing that capillary hemorrhage is capable of relief by medical means alone, medical should always precede surgical treatment. [T. M. T.]

4.—Luke concludes by referring to the Hyderabad Commission's Report as follows: (1) That the mortality from anesthetics had been unduly high and by improved methods and greater care the death rate can be lowered; (2) That ether, when properly administered from an inhaler permitting graduation of the strength of the vapor, is the safest anesthetic for general surgery in temperate climates; (3) That nitrous oxide gas for minor surgery and dental operations should replace chloroform; (4) That chloroform, when given by a carefully trained person, is a comparatively safe body, but in no case devoid of risk; (5) That no age or nationality removes the danger under anesthetics; (6) That the perils of anesthetics, however slight, demand that the undivided attention of a duly qualified and trained medical man be given to the administration of the anesthetic. [T. M. T.]

Original Articles.

TWO SUCCESSFUL CASES OF SECONDARY SUTURE.
ONE OF THE POSTERIOR INTEROSSEOUS NERVE
AND ONE OF THE MEDIAN AND ULNAR NERVES.

W. W. KEEN, M. D., LL.D., F.R.C.S. (Hon.),

CASE I.—*Interosseous nerve, common extensor muscle of the fingers, followed by total loss of extension of the fingers; suture after three months; entire restoration of function.**

W. B. H., of Pine Bluff, Ark., aet. 38, 6 ft. 4¼ in. tall, weight 260 lbs., first consulted me November 6th, 1900, at the instance of Dr. J. L. Goree, of Pine Bluff.

On August 1st, 1900, while camping out and standing in front of a guide, who was chopping down a tree, the ax-head flew off the handle and struck him on the back of the left forearm, 17 cm. below the olecranon and 12 cm. above the styloid process of the ulna, inflicting a wound 5.3 cm. long, and almost precisely transverse to the long axis of the forearm. The wound extended down to the bones, but did not fracture them. A surgeon, who also was camping out in his neighborhood, but with no surgical instruments or dressings with him, closed the wound without suturing the muscles or nerves. The wound healed by first intention.

On examination I found that he could extend the hand at the wrist by the radial and ulnar extensors, but extension of the fingers was impossible. (Fig. 1.)

Dr. Wharton Sinkler kindly examined the electrical condition of the muscles and reported as follows: "The extensors of the left forearm above the incision all respond to the faradic current; below the wound they do not and galvanically there is reaction of degeneration in the lower portion of the extensor communis digitorum. I would infer from this that the nerve had been severed at the same time with the muscles, and that it would be desirable, if possible, to find the ends of the nerve and suture them."

Dr. Spiller made an examination of the sensation and found that there was no loss, except over a small area just below the scar.

On comparing his two hands I found that he had a peculiarity of the two thumbs. Abduction of the meta-carpal bone of the thumb was very poor on both sides, and was scarcely greater on the uninjured than it was on the injured side.

Operation, November 9th, 1900. I made a vertical incision 13 cm. long in the long axis of the forearm. After reaching the muscle I was agreeably surprised to find that there was no visible evidence of any great gap filled with connective tissue at the point where it had been divided, but that there was only a recognizable linear cicatrix. I

FIGURE 1.

but inability to extend the fingers.

made a blunt dissection down to the interosseous membrane and endeavored to find the prolongation of the posterior interosseous nerve toward the wrist joint, but failed to find it. I did find, however, the posterior branch going to the common extensor of the fingers. This I verified by the battery. At the point of injury the nerve was very much attenuated below the wound and immediately above the wound it was considerably thickened. I first passed a suture both above and below the wound, next removed 7 mm. of the nerve, and then approximated the freshened ends to each other and closed the wound.

His recovery was uneventful, the highest temperature once being 99.6°. He left the hospital November 17th, 8 days after the operation. At that time slight extension of the fingers was already beginning to be possible.

I directed that, after his return home, he should use the hot and cold douche in alternation, active and passive exercise and massage, and especially electricity, beginning with the galvanic current and later the faradic. All this treatment he carefully carried out with the exception of the electricity, for which there was no apparatus available. His wife wrote under the date of January 3rd, 1901: "Mr. H.'s arm has improved most wonderfully, and the

Figure 2.

Appearance of the arm six months after the operation, showing full extension of the fingers.

loss of muscular force is hardly noticeable." A letter received May 1st, 1901, transmits two photographs showing that the fingers and wrist can be extended in a straight line, but he states that when the wrist is in extension he is not quite able to extend the fingers completely. (Fig. 2 shows the same arm with the wound and my incision making a X).

CASE 2. — Incision of median and ulnar nerves; secondary suture after six months; entire recovery.

Chas. D., aet. 16, first consulted me about the middle of April, 1892. In October, 1891, he lost his balance, and, to prevent his falling, thrust his left hand through a pane of glass. The forearm was cut transversely, 2 cm. above the pisiform bone, and when I saw him showed a scar extending from a point 2 cm. from the radial border of the forearm to the internal edge of the ulna. (Figs 4 and 5). Dr. Horton, of Peekskill, New York, where the boy was at school, states that the cut extended completely down to the bone, severing all the tendons, and divided the median and ulnar nerves and the ulnar artery. Dr. Horton ligated the artery and desired to suture the tendons and nerves at the time of the accident, but was overruled by an older practitioner.

On examination I found that he had control over the thumb and forefinger in flexion and extension, but they were weak. The thumb could not be apposed to the other fingers. The three ulnar fingers were all in a state of flexion and could not be extended except partially upon strong flexion of the wrist. The thenar and hypothenar eminences were entirely wasted. His grasp was good if anything was placed in the flexed fingers. Sensation was with difficulty ascertained, but it was evident that there was no absolute anesthesia at any point. The radial surface of the little finger was the duldest, and even there a light touch was perceived, though not sharply. The whole hand was purplish and very cold.

Operation, April 21st, 1892. A longitudinal incision was made over the ulnar nerve, the incision being extended finally downward over the hypothenar eminence about 4 cm. below the wrist and 9 cm. above the wrist. The upper bulbous extremity of the ulnar nerve was easily found, but was fused in a mass of connective tissue. In order to find the distal end, the cut was prolonged, as stated, over the hypothenar eminence. The ulnar nerve was found there, not wasted, but above the normal size, the upper end being directly continuous with one of the superficial flexor tendons. Both ends of this nerve were loosened, resected and both stretched, the upper end especially yielding. With some little tension the two ends could then be brought together and were sutured with one fine silk thread. Through the same incision the median nerve was then found with some difficulty. At the level of the cicatrix, the two ends had united, and at the same point another flexor tendon joined them in a bulbous mass. I debated for some time whether to excise this mass and attach the two ends of the nerve together after stretching, but finally decided to sever the connection of the tendon with the mass and let the nerve alone. If the nerve did not improve a later resection could be done. The tendons I found in one general cicatricial mass. As it was impossible to differentiate the individual tendons, I contented myself with elongating the deep flexors by the method of tenotomy which I devised. (Trans. College of Physicians, March 4th, 1891). The superficial flexors I severed obliquely and attached them at a distance by several strands of catgut suture. The gap between the two ends was 2 cm. The hand was then placed on a splint.

April 25th, (fourth day). No opportunity was offered for testing sensation through the dressing, excepting by touching the last two joints of the fingers that were exposed. This showed that the ring and little fingers were devoid of sensation, the ring finger not only on the ulnar, but on the radial side. The sides of the other two fingers and the thumb showed sensation. To-day he perceived a prick over the ulnar fingers for the first time. He returned the next day to Peekskill.

June 2nd (six weeks later), Dr. Horton reports the circulation in the forearm good, motion of the wrist, thumb and forefinger normal, with the exception of extreme extension of the wrist. Sensation of the three ulnar fingers

is not very acute, but is improving. The blueness of the nails which was first noticed is rapidly passing away.

November 25th, 1892, (seven months). I examined him to-day. The general condition of the hand is good, the ring and little fingers are a little purplish and also a little cold, but not at all to the same degree as before the operation. Sensation exists in all parts of the hand. He can move any part of the hand, except the ring and little fingers, and even over these two fingers he can feel and localize a pencil point. Motion in the thumb, middle and index fingers is excellent, and he can grasp objects, though not with great strength. Flexion in the two ulnar fingers is limited to the last phalanges, there being as yet no flexion at the knuckles of these fingers.

Ever since the operation he has been using continuously massage, electricity, hot and cold douche, active and passive exercise.

April 9th, 1893, (one year later.) His hand has improved immensely. He can touch the tip and the base of each finger with the end of his thumb, can make a fist, the fingers being in almost complete flexion and his grip is good, little, if any difference being perceptible in the grasp of the two hands. Each finger can be moved independently of the others, the motion of the little and ring fingers now being nearly normal and the others quite so. Sensation is also perfect.

December 22nd, 1899, (seven years). I re-examined the hand to-day. His grip is wonderfully strong, his fist is as last described. Practically the hand is as useful as ever.

May 15th, 1901 (nine years). He sends me the accompanying photographs (figs. 3 and 4) just taken

Figure 3.

Same as Fig. 1, but motion in forearm and fingers is better.

Figure 4.

Nine years after the accident, showing good extension of the fingers.

to show his power of flexion and extension of the fingers. Though he cannot quite close his fingers, yet practically his hand is as useful as a normal hand.

The photographs presented are the best evidence of the excellent results of the two operations here recorded. Both hands were useless, practically, for the same reason—the want of the power of extension—but from wounds of two entirely different nerves. The wound of the posterior interosseous prevented extension at the knuckles by the common extensor of the fingers, while the wound of the ulnar and median, in the second case, prevented extension of the last two phalanges by the interosseous and lumbrical muscles. I would call attention to the late periods (three and six months) at which the secondary suture was done. In the first case, also, the very speedy return of motion was surprising. It began within a week after the operation and was practically complete within two months. This is the more gratifying, as the posterior interosseous is so small a nerve that I doubted whether I could find it in so muscular a patient, or if I did whether it would hold a thread. Suturing it before excising the point at which it had been wounded was excellent. Had I first excised, the cut

ends would have been considerably, and possibly, irreparably injured by forceps or other means used to seize them and steady them while passing the needle. So far as Dr. J. C. Merrill, of the Surgeon General's Library, in Washington, who kindly had his records looked over, or my own references, show, this is the only case as yet recorded of operation on this nerve.

The second case shows how a younger man, well up in the latest surgical procedures, may be hampered by an older practitioner, who has not kept up with the progress of surgery. Had Dr. Horton's advice been followed and tendon been sutured to its appropriate tendon and nerve to nerve when the accident occurred, in all probability no later operation would have been necessary. That the operation has resulted so happily is remarkable, especially as the tendons had to be united haphazard, one above to one below, with no possibility of ascertaining which belonged to which.

PANCREATITIS.*

By A. W. MAYO ROBSON F. R. C. S.,

of Leeds, England.

Senior Surgeon to the General Infirmary at Leeds; Emeritus Professor of Surgery in the Yorkshire College of the Victoria University.

Mr. President:—

I must first thank you, sir, and the Council, for the great honor done me in inviting me to come to Baltimore and take part in the proceedings of the American Surgical Association, which I consider also a privilege and a pleasure.

Having expressed my views on Chronic Pancreatitis and its relation to Cholelithiasis at the London Polyclinic in June, 1900, and having been invited to open the discussion on Diseases of the Pancreas at the International Medical Congress, in Paris, in August last, I almost regretted having promised to give this paper before the American Surgical Association, lest it might appear as if I were simply giving a *rechauffe* of my views, but it is astonishing how much has recently been written on the subject. Not only have my observations been confirmed by numerous workers who have expressed their views in writing, but from conversations that I have had with surgeons who frequently operate in the abdomen, I learn that nearly all have had one or more cases which they have diagnosed as gall-stones in the common duct for which they had operated, but finding a tumor of the head of the pancreas, they had simply drained the gall-bladder and given a bad prognosis, thinking the disease to be cancer; and only on the complete recovery of the patients had wonder been excited and some other explanation sought. Moreover, my own experience has been increased, and as the result of further observations I have views to advance which will, I hope, produce a useful discussion.

I do not propose to weary the Association with a recital of many cases, a number of which have been reported and can easily be referred to if wanted; but I should like to give what time I have to a brief consideration of the relation between fat ne-

* Read before the meeting of the American Surgical Association, Baltimore, Md., May 1, 1901. Printed from manuscript furnished by the author.

crosis and hemorrhage—to the relation of gall-stones and pancreatic disease and to the treatment of pancreatitis generally.

It is a curious fact that, although surgeons have been removing gall-stones from the common duct for a little over 100 years, i. e., since Courvoisier's first successful choledochotomy, in 1790, and that, although the subject of jaundice dependent on obstructed common duct received great attention from physicians many years ago, yet until comparatively recently, it never seemed to dawn on the minds of clinical observers, that whatever obstructs the common bile duct at its lower end, must also, of necessity, lead to an obstruction in the pancreatic duct; and although, since the description of the disease by Charcot as Intermittent Hepatic Fever, infective and suppurative cholangitis have been well recognized by pathologists, yet infective and suppurative catarrh of the pancreatic ducts even now has received no place in the medical text-books; which means, in reality, that all diseases of the pancreas except those producing gross organic changes, such as cancer, acute pancreatitis, cysts and calculi, have been practically ignored; yet we know, both by post-mortem observation and by surgical experience, that under similar conditions the pancreatic ducts participate in the same inflammatory processes as the bile ducts.

When the common bile duct is obstructed, the objective sign of jaundice at once demonstrates the fact; hitherto, however, no pathognomonic sign has been discovered, which will show conclusively that the pancreatic ducts are occluded, unless it be the extremely rapid loss of weight. As is now well known, the presence of fat necrosis does afford some clue, and a very important one, hitherto only discovered, however, when the abdomen is opened; but even for fat necrosis to take place, there must probably have been some escape of the fat splitting ferment from the gland, and therefore the affection of the pancreas must be somewhat advanced before the sign is evident. Glycosuria, lipuria, and fat in the stools occur too seldom to be of much use in the diagnosis of pancreatic disease, though when present they are of great diagnostic importance. I think that physiological chemistry may, perhaps, help us in the diagnosis, and though our observations are not by any means yet complete, I hope that some researches, at present being conducted on cases under my care, by my friend, Mr. P. J. Cammidge, Pathologist to the West Riding County Council, may prove of practical use, and I have some grounds for hope that by an examination of the urine alone or of the urine, the blood and the feces, we may have some assistance in the diagnosis of these difficult cases.

The pancreas is a racemose gland, well supplied with blood, and, unlike the parotid, the lobules of which are well supported by fibrous partitions, its tissues are comparatively soft in consistence and easily bruised; so that although it is placed in the most favorable position for protection from direct injury, yet a slight injury takes more effect on it than on many other firmer organs, and we have knowledge of pancreatitis resulting from blows in the epigastrium apparently trifling in character. In a case that I saw several years ago, a butler

slipped and fell forward against a knife board projecting from the end of the table at which he was working; the blow was comparatively slight, and the man did not even fall to the ground; but acute, so-called hemorrhagic pancreatitis followed, and the patient died; an exploration for peritonitis followed by an autopsy revealing the true cause of death.

Probably slight injury to the pancreas often occurs in abdominal operations for gall-stones in the common duct, when it is sometimes necessary to manipulate and rather forcibly draw the parts in the neighborhood of the pancreas forward in order to view the common duct when sutures are applied. Such a case has, indeed, been related recently.

When it is borne in mind that the pancreatic duct opens along with the common bile duct into the second part of the duodenum, a channel usually containing septic organisms, especially when it is the seat of catarrh, to which it is especially liable, it is not a matter for surprise that pancreatitis should be met with, but rather that it should not occur more frequently.

As in the liver, we may have simple, infective, and suppurative catarrh of the excretory ducts, as well as inflammation of the interlobular tissues, so in the pancreas, we undoubtedly have similar diseases, which are only awaiting our recognition during life by greater diagnostic skill. As bearing on this, the pathologist of a large hospital has told me that in cases of obstruction of the common duct by gall-stones, he has noticed that pus can usually be expressed from Wirsung's duct, and this has been confirmed by others. I feel sure that, as our means of diagnosis become more perfected, diseases of the pancreas, both functional and organic, will be more frequently recognized and awarded their deserved positions in medicine.

Since my countryman, Mr. Walker, of Peterborough, showed that the absence of the pancreatic secretion from the intestine, even though bile was present in the intestinal canal, led to pale colored motions, very little attention has been paid to this sign, although much has been written about the presence of sugar in the urine in pancreatic disease; yet, glycosuria is, in my experience, a very rare phenomenon in this relationship, and in fact it only occurs when there is great destruction of pancreatic tissues, as in extensive cirrhosis or in extensive malignant disease.

Fat in the stools is more common, but not by any means universal, and lipuria is very uncommon.

I have seen cases of discomfort, with some swelling at the epigastrium, associated with dyspepsia and ague-like attacks, but without jaundice, or with only very slight jaundice, which I thought might be explained on the hypothesis of infective inflammation of the pancreatic duct, the cases having cleared up under general treatment. I have also seen the same symptoms associated with more pain, irregular fever, more marked swelling and tenderness over the pancreas and discharge of pus by the bowel from time to time, but without any collection sufficiently large to form a distinct abscess. I related a case like this in the lecture previously referred to, but the recovery of the patient made the absolute certainty of the diagnosis doubtful, though an examination under an anesthetic enabled a swelling of the pan-

creas to be felt, and this was confirmed by palpitation of the abdomen at a later stage, when tenderness was less marked.

I thought this case was probably a subacute pancreatitis, associated with suppurative catarrh of the pancreatic ducts analogous to suppurative cholangitis.

The essential and immediate cause of the various forms of pancreatitis is bacterial infection, this having been positively proved, both clinically in the human subject, and experimentally in the lower animals; but, as in inflammatory affections of the liver and bile-ducts, we look for extrinsic causes, so in pancreatic diseases we find biliary and pancreatic lithiasis, injury, gastro-duodenal catarrh, ulcer and cancer of the stomach, pylorus, or duodenum, and zymotic diseases, such as typhoid fever and influenza, to be determining factors; though in some cases pancreatitis has come on suddenly in persons in robust health, and the determining cause has been beyond recognition.

Though the infection may arise from the blood, as in pyæmia, or by direct extension from the neighboring tissues, as in ulcer of the stomach, yet the most usual channel is through the duct, as in the cases arising from gall-stones in the common duct and from gastro-duodenal catarrh, that I related in my lecture.

The association of gall-stones with chronic pancreatitis, was absolutely forced on my mind by the frequency with which I found inflammatory enlargement of the head of the pancreas when operating for gall-stones in the common duct: the first instance of the kind having been observed by me in 1892 in a case on which I operated for deep jaundice, supposed to be due to common bile duct obstruction, but in which I found cirrhosis of the head of the pancreas. Since that time I have operated on a considerable number of cases (over 20), and though only one patient has died directly from the operation, in the other two, one a cholecystenterostomy, and the other a cholecystotomy, death occurred within a few months, and the correctness of the diagnosis was verified both by autopsy and by a microscopic section of the diseased pancreas. I am able to show the pancreas from the last case, and also a microscopic section of the specimen. It is a simple matter to infer, that if common duct cholelithiasis can give rise to chronic pancreatitis, it will also be likely to induce the subacute and acute forms of the disease, and this is, I think, now clearly proved. In the *Brit. Med. Jour.* for Nov. 14, 1896, Dr. Kennan described a case of acute pancreatitis, ending fatally on the second day, in a woman of 38, and at the post-mortem examination a large number of gall-stones were found in the common duct, one being partly extruded into the duodenum.

Korte (*Deutsche Chir.*, Stuttgart, 1898) notes that lesions of the pancreas are frequently associated with diseases of the bile ducts. Lancereaux (*Traité des Maladies de la Foie et du Pancréas*, 1898) mentions the possibility that a gall-stone impacted in the diverticulum of Vater may occlude the pancreatic duct and produce conditions favoring the entrance of organisms into that duct. Dr. Opie, in a very instructive and interesting paper in the *American Journal of the Medical Sciences* for Jan., 1901, p. 27, relates

cases, one of Dr. Osler's and several from various sources, showing the relationship between pancreatic and gall-stone troubles. Mr. Gilbert Barling (*B. M. J.*, Dec. 22, 1900) has given several interesting cases bearing out very fully the views expressed above. In some of my cases, gall-stones were not found, but only old and firm adhesions, with an antecedent history of paroxysmal attacks, followed by jaundice, which afforded strong presumptive evidence that cholelithiasis had been present at some time; and it seems quite possible that temporary occlusion of the common duct, with the damming back of infected secretions or with injury to the ducts, may set up a pancreatitis, which may itself then cause compression of the common bile duct and so lead to a perpetuation of the obstructive jaundice and other troubles, started in the first instance by impacted gall-stone.

Fat Necrosis.—By fat necrosis is understood splitting up of the fat into fatty acids and glycerin, the latter is absorbed, but the acids being insoluble remain in the cells and unite with calcium salts, forming yellowish white patches of various sizes in the sub-peritoneal fat and in the omentum, mesentery, etc. It was first described by Balser, in 1882 but has been since investigated by Langerhans, Hildebrand, Dettiner, Milisch, Williams, Flexner, Opie and others. Experiments by Opie, who ligated the pancreatic ducts in the cat, go to show that widespread fat necrosis may be expected to follow very rapidly.

Fat necrosis is commonly found in association with pancreatitis and other diseases of the pancreas, and the relationship between the two conditions has given rise to much speculation; but the facts that fat necrosis is not found in all acute pancreatic diseases, and that it has been noted during abdominal operations for other ailments, and in autopsies where there was no suspicion of pancreatitis, appear to show that the condition giving rise to it is not essentially a pancreatitis, as suggested by certain authors; though these facts do not disprove that fat necrosis is essentially due to interference with the discharge of pancreatic secretion, and so to an escape of pancreatic fluid into the tissues, whence it may be taken up by the lymphatics or blood vessels. Flexner (*Contribution to the Science of Medicine*, Johns Hopkins Press, Baltimore, 1900) and others, regard the fat necrosis as the effect of the fat splitting ferment of the pancreatic fluid, which has in some way escaped from the duct into the surrounding tissues. It is difficult at first sight to explain the patches of fat necrosis occurring at a distance from the pancreas, for instance, in the pericardium, unless it be by absorption of the ferment and its diffusion by means of the lymphatics; though this is easy to understand, and undoubtedly does explain the disintegration of the fatty tissues immediately surrounding the pancreas and extending by continuity first to adjoining, and then even to distant parts in the abdomen and thorax.

Hæmorrhage in the Pancreas.—It is well known that local hæmorrhages into the pancreas may occur apart from injury and apart from any general hæmorrhagic tendency, and that although they may be recovered from, as shown by the remains of extravasated blood in the gland in persons dying from other diseases; yet such spontaneous hæmorrhages

may lead to death from collapse either immediately or after some hours. Curiously, this may occur in persons apparently in good health and without any premonitory signs on which a diagnosis can be based, the only symptoms at the time being those of collapse with dyspnea and feeble pulse. It is also well recognized that a hemorrhagic condition may co-exist with cancer of the head of the pancreas. Some years ago I thought this to be altogether dependent on the cholemia, until increased experience in operations on deeply jaundiced subjects has taught me that there is much less danger of serious hemorrhage in patients jaundiced from gall-stones than in those where the jaundice depends on pancreatic disease. In several cases of cancer of the pancreas on which I have operated, the bleeding has been the immediate cause of death; in one aged subject especially this was well marked, after a cholecystotomy for the relief of jaundice. Death occurred on the third day from collapse, and at the autopsy there was found extensive effusion of blood away from the site of operation and behind the peritoneum, extending into the loins around the kidneys, and into the cellular tissue beneath the diaphragm, the blood being in sufficient quantity to account for death; and though the bleeding had evidently arisen from the pancreas, there was no manifest vascular lesion to account for the hemorrhage. In another case, sent to me in 1888 by Professor Clifford Allbutt, a cholecystotomy was followed by persistent oozing of blood from the interior of the gall-bladder and from the stitch punctures, which resisted all then known remedial measures in the way of styptics, pressure, transfusion, etc., and proved fatal on the 9th day. In neither of these cases was there any peritonitis or cause other than the hemorrhage to account for death. Now, in another patient equally deeply jaundiced, that I saw with my colleague, Dr. Churton, in '89, but in which the disease was dependent on cancer of the common bile duct above the entrance of the pancreatic duct, there was no hemorrhage, although the patient survived several weeks and died from exhaustion due to the disease and to the suppurative cholangitis accompanying it. I could give many similar comparisons showing the difference between the behaviors of the blood in the two classes of cases. Before operating on these cases, I now always administer chloride of calcium in 30 to 60 grain doses thrice daily for from 24 to 48 hours previous to operation, and by enema in 60 grain doses thrice daily for 48 hours afterwards; this is nearly always successful in correcting the hemorrhagic tendency. The following case illustrates as well as any case could, how the failure to give it after operation led to hemorrhage, and how its administration in heroic doses apparently saved the patient:

Cholelithiasis: deep jaundice: chronic pancreatitis: Duodenocholedochotomy: hemorrhage: recovery. Reported by Mr. Gough, House Surgeon. Mrs. M. E. G., aged 38, was admitted to the Leeds General Infirmary on January 23, '01, with the history that she had had typhoid fever in September, 1899, and that she had never been quite well since. Shortly afterwards she began to suffer from biliary colic, though she had never been jaundiced till six months before admission, from which time jaundice had never left her. On December 24th, 1900, she became much worse, and had very severe paroxysmal pain accompanied by shivering and profuse sweats. From that time she lost weight very rapidly and the jaundice deepened. On admission the liver could be felt below the ribs and there was a dis-

tinct fulness on deep palpation in the region of the pancreas. From January 21st to the 31st she took chloride of calcium in 20 gr. doses thrice daily.

January 31st duodenocholedochotomy was performed. There was very little bleeding. A stone nearly as large as a pigeon's egg was removed from the ampulla of Vater, which was laid open over a director introduced through the papilla at its opening into the duodenum. The head of the pancreas was felt to be much enlarged and hard. The incision into the ampulla was not sutured, but through it the common bile duct very much dilated was explored by the finger. The anterior wound in the duodenum was then sutured and the abdominal wound closed. A drainage tube was inserted through a stab wound in the right loin. The patient inadvertently did not have chloride of calcium given in the nutrient enemata as is usual in these cases. She did well till the morning of the 2nd of February, when the nurse noticed at 3 A. M. that the dressings were soaked with bright blood.

The drainage wound was exposed but no hemorrhage was occurring there. On examining the abdominal incision blood was seen to be slowly oozing from it and the stitch punctures. One drachm of chloride of calcium was at once administered by the mouth and three stitches were removed, the surface of the wound was then seen to be oozing all over. It was packed with gauze soaked in tincture of hamamelis and a firm dressing applied. 1 drachm of chloride of calcium was given again in two hours and afterwards repeated in 30 gr. doses every two hours six times, it being then given thrice daily. There was no recurrence of hemorrhage and the patient made an uninterrupted recovery. The drainage tube was removed on February 4th and she returned home within the month.

In this case Mr. Cammidge found the characteristic crystals in the urine and an examination of the blood showed a very marked diminution in the blood plates.

These arguments are brought forward to show that there is some, as yet ill understood, relation between pancreatic disease and serious hemorrhage, but I cannot help thinking that it is a mistake to allow this fact to influence our views on the pathology of inflammation by adopting permanently the name hemorrhagic pancreatitis in cases where there has been no bleeding or no more than occurs frequently in inflammation of other parenchymatous organs, though it may be useful to retain the name for those cases of pancreatitis associated with well marked interstitial hemorrhage, in which the disruption of the gland by the bleeding may be the direct cause of the inflammation.

I have recently read a very interesting paper in the Boston City Hospital Report, for December, 1900, by Dr. F. B. Lund, entitled: "Acute Hemorrhagic Pancreatitis and its Surgical Treatment; with a Report of Six Cases," yet in remarking on the second case, the author says: "This case is notable for the absence of pancreatic hemorrhage." In the fifth case there was the evacuation and drainage of a small abscess of the pancreas and no evidence of hemorrhage, and in the sixth case, also, there was apparently no evidence whatever of hemorrhage. The title of the paper is surely a misnomer; yet other authors adopt the same nomenclature in the same indefinite manner. Dr. Flexner produced an inflammation of the pancreas associated with hemorrhage within 48 hours, by injecting the *Bacillus pyocyaneus* and the *B. diphtheriae* into the pancreatic duct in animals (*Contributions to the Science of Medicine*, Baltimore, 1900, p. 743). Hlava also produced hemorrhagic pancreatitis by injecting the *B. diphtheriae* into the pancreas. Hildebrand (*Centralblatt fuer Chirurgie*, 1894, band 22, p. 297) suggested that the hemorrhage in acute pancreatitis was due to trypsin.

The facts concerning hemorrhage in diseases of

the pancreas and the conclusions we have come to, after carefully considering the whole subject, are: (1) That in certain diseases of the pancreas there is a *general* hemorrhagic tendency which is much intensified by the presence of jaundice. (2) That hemorrhage may apparently occur in the pancreas unassociated with inflammation, or with jaundice, or with a general hemorrhagic tendency. (3) That both acute and chronic pancreatitis can and do frequently occur without hemorrhage. (4) That some cases of pancreatitis are associated with local hemorrhage.

From these conclusions, I think, therefore, that inflammations of the pancreas may be more conveniently and scientifically classified like inflammation of other organs, as acute, subacute, and chronic, and that there is no reason to use the term hemorrhagic pancreatitis, except as a variety of acute pancreatitis, the hemorrhage being merely an accident in the course of the disease.

It seems to me worth while considering if the glycerine set free in the tissues by the fat necrosis may possibly be the real cause of the local hemorrhagic tendency in pancreatic affections, though our observations are not yet sufficiently far advanced to say that this is an adequate explanation of all the cases. While inquiring into the subject, I have become acquainted with certain very important facts bearing on the question. If glycerine in very small amount be injected into mice, it rapidly produces hematuria (Cambridge) or hemoglobinuria, due to destruction of the blood corpuscles; and in certain cases in which glycerine has been used by gynecologists for the purpose of inducing abortion and in others where it has been injected along with iodoform for the treatment of tubercular disease in the human subject, blood has also been noticed in the urine, sometimes in large quantity.

The blood conditions, about to be mentioned, may possibly serve to explain the general hemorrhagic tendency in cases of chronic pancreatitis associated with jaundice, but behind this there must be some other cause not yet discovered. Can it be due to something absorbed from the pancreas into the blood, which only acts when the absorption has been active over a prolonged period of time. This matter seems to me to be worth attention, and it should be possible to prove or disprove it by experimental work.

In discussing these matters with Mr. Cambridge, he suggested that only a small amount of glycerine could obtain access to the blood as the result of fat necrosis. When the glycerine is set free and the fatty acids are saponified, it would become oxidized just like any other alcohol, and the oxidation products for which one would look would be an aldehyde, but the tests employed failed to demonstrate this.

In the course of these investigations, however, it was found that if the urine was boiled for a short time with an oxidizing agent and then the phenyl hydrazine test performed, an abundant crop of delicate yellow needles arranged in sheaves and rosettes was produced. (Specimen shown.)

The untreated urine gave no such result; normal urine, morbid urines from gout, etc., and, most important, bilious urine from patients suffering from simple catarrhal jaundice, also gave negative re-

sults. I may say also that some experiments performed on bile and bile salts yielded none of the crystals.

The number of cases is too few to allow one to more than suggest that it may prove useful as a diagnostic test in this class of cases, but it is also interesting to note that on one day I operated on two patients deeply jaundiced, in one of which there was chronic pancreatitis, whereas in the other, although there was a small gall-stone in the common duct, there was no manifest enlargement or disturbance of the pancreas. Both urines were submitted to Mr. Cambridge, and without his knowing the history of either case he sent me word that the urine in the latter case (where there was no pancreatitis) gave negative results so far as the crystals were concerned, and that in the former case, just described at length, he was able to obtain abundant crystals.

An examination of the blood has also been made in a number of cases, with a view to ascertain if any information can be found to explain the hemorrhagic tendency. Although glycerine may be present, Mr. Cambridge knew of no test sufficiently delicate to demonstrate its presence in the blood.

A histological examination of the blood showed in two of the cases a very striking diminution in the number of blood plates as compared with the normal blood. This diminution of the blood plates, whatever may be its cause, may possibly explain the general hemorrhagic tendency in these cases.

Treatment of Acute Pancreatitis.—In acute infective pancreatitis, treatment practically resolves itself into that of peritonitis, commencing in the superior abdominal region. The pain at the onset is so acute as to necessitate the administration of morphia, and the collapse will probably demand stimulants, which, on account of the associated vomiting, may have to be given by enema. In the early stages the symptoms are usually so indefinite that the indications for surgical treatment are not clear enough to warrant operation, and until the collapse has passed off no surgical procedure would generally be justifiable. The stimulation of intestinal obstruction will probably lead to efforts to secure an evacuation of the bowels and relief of the distension.

Just as in a perforative or gangrenous appendicitis, an early evacuation of the septic matter is necessary to recovery, so in this equally lethal affection, an early exploration from the front through the middle line above the umbilicus, or from behind through the left costo-vertebral angle is demanded, in order to evacuate the septic material and adopt free drainage.

The after treatment should be chiefly directed to combating shock and keeping up the strength until the *materies morbi*, both local and general, can be thrown off.

Even if no pus be found, no harm should accrue by such an exploration, which can be made in a few minutes through a very small incision in the middle line above the umbilicus, if necessary with the aid of cocaine anesthesia. After establishing the diagnosis by the anterior small incision and the introduction of a finger, the posterior incision, which must be a free vertical one in the left costo-vertebral angle, so as to permit the insertion of the whole hand if thought desirable, will enable the diseased

organ to be very freely examined and, if necessary, drained for the evacuation of pus and gangrenous material, thus involving no risk to the general peritoneal cavity and little danger of retained septic matter, as the drainage will be a dependent one.

Treatment of Subacute Pancreatitis.—The subacute form of pancreatitis is more amenable to treatment, as the indications are so much more definite and there is more time for careful consideration; and though it has usually only been attacked when an abscess has formed and is manifestly making its way to the surface, yet there is no reason why in some cases surgical treatment should not be adopted at an earlier stage. As in the acute condition, morphia may be required to relieve the collapse and support the strength.

Distension, if present, may also demand attention, and may have to be relieved by lavage of the stomach and turpentine enemata or by the administration of calomel by the mouth. Calomel is also of benefit by acting as an intestinal antiseptic; for which purpose it may be given in small repeated doses or in doses of five grains, followed by a saline aperient. As soon as the constipation is relieved, diarrhea is apt to supervene, when salol and bismuth with small doses of opium may be given. If surgical treatment is decided on, a median incision above the umbilicus will enable the operator to palpate the pancreas and locate any incipient collection of pus, which, if practicable, should then be evacuated by a posterior incision in the left or right costo-vertebral angle; or, if the posterior incision be thought impracticable, the collection of pus may be aspirated and the cavity opened and packed with gauze, which may be brought forward through a large rubber drainage-tube, that will in the course of from 24 to 48 hours establish a track isolated from the general peritoneal cavity. In one case I was able to do this, but the operation was undertaken at too late a stage to be successful, and though the patient lived two or three days afterwards, the evacuation of the pus seemed to make very little difference in the general septic condition previously existing, and death occurred on the 4th day from increasing debility. The method adopted had, however, been successful from the point of view of drainage, and the track of the gauze and tube had been isolated from the general peritoneal cavity. If a definite abscess forms and approaches the surface in front or in either loin, the treatment will be that of incision and drainage, as in the case of any other abdominal abscess. Of five cases on which I have operated, three recovered completely, one recovered from the operation, but died a few weeks later from chest complications and debility, and the fifth case is the one just referred to. The strength must be maintained by careful feeding and the administration of stimulants, and it will be necessary to keep a sharp lookout for further collections of pus and for subphrenic abscess or empyema, which, on recognition, will need treatment.

The following case of pancreatitis is so exceptional, both with regard to course and treatment, that I think it is worth relating:

Chronic gastric ulcer eroding pancreas; pancreatitis; abscess of pancreas bursting into stomach. Vomiting. Impending death. Posterior gastro-enterostomy. Recovery.

On November 12, 1900, I was asked by Dr. Mercer, of

Bradford, to see Mr. R., who was extremely ill and supposed to be suffering from pancreatic disease.

On arrival I found the patient, aged 35, extremely emaciated, lying in a typhoid condition, vomiting extremely offensive dark-colored pus and mucus mixed with blood. He was extremely feeble and had a rapid weak pulse and a slight icteric tinge in the conjunctivae, a tumor could be felt above the umbilicus which was tender to pressure. On distending the stomach with CO₂ great pain was produced and vomiting followed. The stomach was dilated, reaching on the left side to the level of the umbilicus.

There had been an elevated temperature for a few weeks, but this had become subnormal after the vomiting of pus. Pain after food and indigestion had existed for some months, during which time there had been steady loss of flesh; but recently, especially during the last months, the wasting had been very considerable. There was a little sugar in the urine with a trace of albumen and the feces contained free fat.

No medicine had done any good either for the relief of the vomiting or in controlling the horrible odor, which permeated the whole house. A diagnosis of chronic gastric ulcer of the posterior wall of the stomach with secondary ulcerative pancreatitis and abscess of the pancreas was made, and gastro-enterostomy proposed as the only means likely to produce any chance of relief, but even that seemed almost hopeless.

He was removed to a surgical home by ambulance and the stomach washed out carefully by Dr. Stevens. As showing the nature of the stomach contents, both the attendant nurses were made sick by the odor of the material evacuated by the tube.

On November 18th after enveloping the patient in cotton wool and subcutaneously administering strychnine, posterior gastro-enterostomy was performed, a bone hobbin being used. The operation was done as quickly as possible in order to save shock. The tumor felt before operation was found to be formed by stomach and pancreas firmly fixed together towards the pyloric end, but leaving the dilated portion free at the cardiac end of the stomach, so that no difficulty was found in doing a satisfactory operation, which was completed in 20 minutes. Saline subcutaneous injections and rectal injections were given and strychnine was freely administered, but for two days we had a great fight with death apparently due to poisoning with the foul stomach contents. Hot water was freely given to induce vomiting on the second day, as the patient could not bear the stomach tube being used. This gave relief, and afterwards progress to recovery was uninterrupted. He rapidly gained strength and put on flesh, returning home five weeks after operation. His friends, who had despaired of his recovery, were astonished to find him so well. In April he was in such good health that he married.

The treatment of Chronic Pancreatitis is also by abdominal section and drainage, but in this case the drainage is indirect and obtained by draining the gall-bladder by cholecystotomy, cholecystenterostomy, or duodeno-choledochotomy. The exact line of treatment cannot be determined until the abdomen is opened, and for this purpose I prefer, as in all my gall-bladder operations, a vertical incision through the upper part of the right rectus, splitting that muscle to whatever extent is necessary in order to obtain a good view of the diseased region, and to afford plenty of room for manipulation. If a mere cholecystotomy on a distended gall-bladder is necessary, an incision of one or two inches will usually suffice; but if the gall-bladder is contracted, or if the ducts have to be attacked, an incision of 4 to 6 inches will be required, and if the several layers of the abdominal wall are sutured separately, there is no fear of subsequent hernia; this I can affirm by ample experience. It saves much time and much unnecessary dragging on the parts when operating on the common duct or duodenum, to have a free incision, and there is no retractor equal to the hand of a skilful assistant, who, with a flat sponge, interposed between the spread-out fingers of his

left hand and the viscera, will at the same time afford the operator a good view of the field of operation, and with his right hand help in the further steps of the operation.

If the right costal margin or the edge of the liver obstructs the view, another assistant may with advantage, retract it either by digital manipulation or by means of a wide retractor with a long handle, so that he can stand back a little and avoid embarrassing the operator. As a matter of experience, I seldom find a second assistant necessary. A sponge in the pouch to the right of the common duct and one pushed down over the right kidney, helps to catch all escaping fluids and to keep the peritoneum clear. When the ducts or the duodenum are opened, sterilized gauze pads are employed to mop up the fluid as it escapes, but none of these are allowed to remain even temporarily in the abdomen. When there are gallstones present, they should be removed, unless the patient is too ill to permit of the complete operation; but in every case drainage must be secured, if possible by cholecystotomy, as in nearly all my successful cases; moreover, the drainage must not be stopped before the bile has become healthy and not before the greater amount of bile is being passed by the bowel, which will be certain to occur as soon as the swollen pancreas has subsided, if the duct be otherwise clear of obstruction.

It might be thought that cholecyst enterostomy would be an ideal operation in the treatment of these cases, but experience says it is not. For instance, in one of my cases the operation brought about so much relief that a cure was being anticipated, yet in the third month relapse occurred and death ensued, apparently simply owing to closure of the new opening between the gall-bladder and duodenum. In one of Mr. Barling's cases (*B. M. J.*, Dec. 22, 1900), where the gall-bladder was joined to the duodenum, he states that although the symptoms were relieved, enlargement of the pancreas persisted. The course and treatment of chronic interstitial pancreatitis is exemplified in the cases related in my lecture before the Polyclinic in June of last year. Possibly, in some of these, the manipulation of the indurated tumor may have detached calculi impacted in the pancreatic duct, though I was unconscious of it; but in others, the relief of tension, as the result of draining the bile ducts by cholecystotomy or cholecyst enterostomy, indirectly drained the pancreatic duct and thus led to a subsidence of the pancreatitis, then to an opening of the common duct by the relief of the tension, and so to a cure of the patient. The simulation of malignant disease of the head of the pancreas by chronic interstitial pancreatitis would make me hesitate to decline operation in any case of distended gall-bladder where the patient is in a condition to bear it, or even in any case of chronic jaundice without distention of the gall-bladder where the general health is deteriorating; as, though it should be recognized that if the disease be really malignant, very little good will be done and life may even be shortened or only prolonged for a short time; yet, if the disease prove to be chronic pancreatitis, a real and permanent cure may be brought about. If a calculus be felt imbedded in the head of the pancreas or impacted in the pancreatic duct, it may be reached through

the second part of the duodenum by laying open the papilla and exploring the duct, or by dividing the peritoneum, passing between the duodenum and hepatic flexure of the colon, and then cutting through the overlying pancreas on to the concretion. If the papilla common to the bile and pancreatic ducts be incised in the duodenum it does not require suture, and in the cases in which I have explored the ducts by the duodenal route, there has been no serious hemorrhage; the anterior duodenal opening only requires closing by a mucous and a serous suture. Drainage of the right kidney pouch for from 24 to 48 hours is advisable, though not always necessary, and this is best done by a stab wound at a most dependent part.

The results of treatment in this class of cases have been most encouraging, as out of 22 cases operated on, only one died directly from operation, and in that case the patient's life was only very slightly shortened, since he was reduced to the last stage of exhaustion before a surgical opinion was sought. Of those recovering from operation, with the exception of two that died a few months later, complete and perfect recovery ensued. These results contrast very markedly with the surgical treatment of cancer of the pancreas, where nearly half the cases operated on have died directly as the result of operation, and in those who have survived, life has only been prolonged for a comparatively short time.

Of the three following cases, two have not been previously reported.

CHRONIC PANCREATITIS; CHOLECYSTOTOMY; CURE.

Mr. D., aged 45 years, was brought to see me 19.3.93, the history being that he had been well up to 12 months before, when he began to have painful attacks at the pit of the stomach, ending in vomiting, but not followed by jaundice until an attack on January 1st, 1898, since which time he had been deeply and continuously jaundiced. He had also from that time onward had ague-like attacks, and two days before seeing me he had had within 24 hours three of these seizures, each accompanied by pain. Within a twelvemonth he had lost 2 stone, 8 pounds in weight. On examining him there was some swelling in the gall-bladder region but no tenderness. The liver was a little enlarged but the margins felt smooth. There was decided tenderness in the middle line just above the umbilicus and on deep pressure the pain was considerable and an indefinite fulness could be felt. The diagnosis of gall-stone in the common duct was made, and an operation was advised. The patient was operated on at a surgical home on March 30th, when the gall-bladder was found to be slightly distended and surrounded by adhesions to the pylorus, duodenum, colon, and omentum. No gall-stones could be discovered, but there was a well-marked swelling of the head and the first two inches of the pancreas which though nodular was not very hard. This extended further to the right than normal so as to cover in the lower end of the bile-duct. Cholecystotomy was performed. Within 24 hours of the operation nearly four pints of very offensive bile was discharged through the tube. A specimen was examined by the Clinical Research Association and their report was as follows: "The bile contains both staphylococci and streptococci, but no bacillus coli communis could be found either under the microscope or in the culture." Fearing that the disease might be malignant and the patient being so extremely weak and ill I gave a poor prognosis, but in a few days I was able to write: "The patient is progressing very satisfactorily, although he is still profoundly weak. Bile has appeared in the motions so that the obstruction is evidently overcome. The bowels have been moved naturally and the patient is less deeply jaundiced and looking better generally." On April 5th I was able to report that he was taking food well and that bile was passing freely in the motions. He had had no recurrence of the shivering attacks. The drainage

was continued for 14 days. On the 20th he returned home. The urine was then free from bile and the motions were assuming a natural color; he was taking food well, gaining flesh, and looking better generally. I still, however, gave a guarded prognosis, though I said that I hoped that the tumor would prove to be inflammatory and not malignant. From that time onward his progress to recovery was extremely rapid. A report I had of his condition a few months later said that he was perfectly well in every respect and that he had fully regained his lost weight.

On March 28th of this year I had a letter from Mr. D., on the third anniversary of his operation expressing his gratitude and saying that he was in perfect health.

CHRONIC PANCREATITIS WITH ABSCESS ASSOCIATED WITH GALLSTONES. CHOLECYSTOTOMY, RELIEF. DEATH FOUR MONTHS LATER FROM EXHAUSTION. AUTOPSY.

Mr. H., aged 40, seen by me with Dr. Woods, of Batley, on the 11th of October, 1900. The patient was then deeply jaundiced and extremely ill, suffering from continuous fever with exacerbations, great debility and extreme emaciation. A large tumour in the region of the pancreas could then be felt as well as a distended gall-bladder. He gave the history of failing health for 9 months and a history of gallstone attacks and painful indigestion for some time before that, but although he had frequent attacks of abdominal pain for 3 or 4 months, the jaundice had only supervened a fortnight before my seeing him. At the operation he was too ill to bear a prolonged search and there were numerous adhesions around the tumor, which was made out to be a swelling of the pancreas; the gall-bladder was simply opened and drained of a quantity of muco-pus. A quantity of pus was discharged from the drainage tube several days after operation and this was repeated on two or three occasions, as if it came from a deeply seated abscess. A large drainage tube having been used, there was a free discharge of bile and a considerable number of gallstones were evacuated through it, 33 in all. Previous to the operation the patient was suffering from shivering attacks and a persistently elevated temperature, which subsided immediately after drainage was effected and the temperature kept nearly normal throughout the remainder of his illness, it being normal in the morning, though there was usually a hectic rise each evening. He made a slow though apparently steady recovery from the operation, and the pancreatic tumor diminished so rapidly that it was confidently believed to be entirely disappearing, it being only one third as large as at the time of the operation. He returned home December 14th, but he never really picked up strength, and though there was no further elevation of temperature, he gradually got weaker and died in February.

At the post-mortem examination made by Dr. Woods, a tumor of the pancreas was discovered which was carefully examined by Mr. Cammidge and pronounced to be a chronic inflammatory tumor and not new growth, the center being occupied by pulpy material where the abscess had originally been. Nothing else was discovered and there were no gallstones left, either in the gall-bladder or ducts. I am able to show you the specimen and also a microscopic section of the preparation for both of which I have to thank Mr. Cammidge.

CHRONIC PANCREATITIS, CHOLECYSTOTOMY.

On the 28th of January, 1901, Mr. E. R. H., aged 26, was sent to me from Malvern. He was deeply jaundiced and told me that he had had jaundice since the age of 17, it having supervened upon a severe attack of what appeared to be biliary colic, of which he had had several seizures since the age of 14. For two or three years he had had several ague-like attacks and during that time lost very seriously in weight and strength, but during the past two years there had been no shivers and he had also been free from the severe paroxysms of pain, though he had had slighter seizures, after all of which the jaundice became more intense. The patient was then only weighing 9 stone and all the bile was apparently passing in the urine and none in the motions. There was also some swelling in the region of the pancreas, slight enlargement of the liver, and a very decided enlargement of the spleen.

Four days later, the abdomen was opened by a vertical incision through the right rectus. The gallbladder was found contracted and surrounded by numerous adhesions. After the separation of these, the ducts were carefully ex-

ploded but without discovering any gallstones. The head of the pancreas was found to be enlarged and very hard. As the obstruction appeared to be entirely due to the pressure exercised by the pancreas on the common duct, the gallbladder was drained. For a few days the jaundice was deeper. It then became gradually less until it almost disappeared. In 10 days the stools became bile stained and have since retained their colour, though there has never been complete freedom from a tinge of jaundice in the skin. He returned home on the 16th of April, having gained nearly half a stone in weight. He looked and felt much better and as a small quantity of bile was still coming from the tube it was felt desirable to retain it until the last tinge of jaundice had disappeared. From the first week of operation up to the present he has had no further pain and has been able to take ordinary food and to digest it well.

THE EXAMINATION OF THE BLOOD IN RELATION TO SURGERY OF SCIENTIFIC BUT OFTEN OF NO PRACTICAL VALUE, AND MAY MISGUIDE THE SURGEON.

By JOHN B. DEEVER, M. D.,

of Philadelphia.

Surgeon to the German Hospital, Philadelphia.

The object of this paper is not to decry the value, to the surgeon, of examinations of the blood; for we undoubtedly can, by this means, often obtain valuable information as to the nature and progress of pathological conditions that can be obtained in no other way. Yet valuable as this sign is, its usefulness is confined to quite narrow limits, and even in its proper field its significance is frequently very difficult, and sometimes impossible, to determine.

The blood count is a valuable physical sign, but it is only one sign, and should be kept in its proper perspective. One spot is not sufficient evidence upon which to base a diagnosis of typhoid fever, nor can the presence of pus be asserted or denied from an estimation of the number of leukocytes alone.

In the last few years there has crept into the profession a tendency to replace the bedside by the laboratory as the point from which to make the diagnosis; to substitute the highly magnified but extremely limited field of the microscope for the broader view of the eye of the physician. This we regret, for in the majority of instances the diagnosis must be made at the bedside without the aid of the microscopist, and any man who has no confidence in diagnosis made without the aid of the laboratory limits his usefulness.

The blood count theoretically promises the surgeon more, perhaps, than any other of the lines of laboratory investigation, and is certainly of great practical value, yet the information thus obtained is open to many fallacies, and the surgeon who depends on this means alone to decide for or against operation in any condition, is often acting to the detriment of his patient.

The technique of a blood count is one in which there are opportunities for inaccuracies without number, and the dilution with which it must be made multiplies each error a hundred fold. Therefore, except in the hands of an expert, its evidence is always open to a reasonable doubt, and even with an expert it is only on repeated examinations that absolute dependence can be placed.

*Read before the American Surgical Association in Baltimore, May, 1901.

The secret of life-saving surgery is promptness in diagnosis and operation, and often the time lost in awaiting the confirmation of our opinions by the laboratory can be ill-afforded by the patient.

An effort has been made lately to determine the exact degree of anemia below which it is unwise to attempt a surgical operation. In this we are asking more of a blood count than it will ever be able to give. In medicine we are dealing with living organisms, with widely varying powers of resistance, and therefore the degree of anemia compatible with successful surgery will vary with each patient. Then, too, what the operation promises is another important factor; for we are certainly justified in attempting an operation, which, if successful, will restore our patient to health under conditions that would positively forbid a merely palliative operation.

To illustrate this, let me briefly cite two cases that have recently occurred in my practice:

CASE 1.—Mrs. L. B., 55 years old, was admitted to the German Hospital 12/20/1900, and the following history obtained: Family and previous history negative. Menstruation physiological until three years ago, when she apparently reached the menopause in a perfectly normal manner. After an interval of eight months an excessive metrorrhagia appeared, accompanied by a profuse offensive leukorrhea. One year after a fibro-myoma was expelled from the uterus; this was followed by a temporary improvement, but six months later the symptoms were as bad as ever, and she has steadily and rapidly lost strength and weight ever since.

On admission the patient was extremely emaciated with that bronzing of the skin very suggestive of malignant disease, and so weak that she was hardly able to raise herself in bed. She had a very offensive leukorrhea and an almost constant metrorrhagia. A large, hard mass could be easily made out connected with the uterus and rising above the symphysis pubis.

The cervix was patulous and presenting at the internal os can be felt a large fibroid.

On the day after admission her blood count was: Hemoglobin 27%, erythrocytes 4,070,000, leukocytes 5,200. She was put under appropriate treatment, but showed only the slightest improvement. On 12/31/1900, the blood count was: Hemoglobin 30%, red blood cells 3,980,000, whites 5,400. Despairing of much improvement by delay, she was then operated upon. A large multinodular uterine fibroid was removed by an abdominal panhysterectomy and the wound closed without drainage. Convalescence was uneventful and the patient left the hospital 2/11/1901 in good health. She has been seen within the last two weeks and reports herself to be perfectly well.

CASE 2.—Mrs. M. C., 48 years old, was admitted to the wards of the German Hospital with the following history: A brother died of cancer of the stomach, but the family history was otherwise negative. Previous personal history negative, menstruation always physiological. No metrorrhagia or excessive menorrhagia. For the last six years has been conscious of a mass in the lower abdomen, and during this time has lost about forty pounds in weight. For the last two years has been extremely weak and short of breath.

Examination on admission shows the patient to be a tall thin woman with all the inspection symptoms of carcinoma. A soft blowing murmur was heard at the base of the heart. The blood count on the day of admission was: Hemoglobin 22%, erythrocytes 2,980,000, leukocytes 5,200. A large mass could be felt in the lower abdomen, both by vaginal and supravaginal palpation.

She was operated on the next day and a large fibro-myoma removed by an abdominal pan-hysterectomy, wound closed without drainage. Convalescence was uneventful and the patient left the hospital 2/11/1900 in very good condition.

Grave anemias are, of course, a general contraindication to an anesthetic and operation in the

same way that organic heart lesions and nephritis are, yet we all know how often the severest operations are successfully performed in the presence of these complications.

Sometimes in a patient suffering from prolonged suppuration, frequent hemorrhages or other conditions that would lead us to expect a profound anemia, we find either a normal or abnormally high percentage of hemoglobin and erythrocytes. Such results are often very misleading, as they by no means express the blood condition of the patient. The chief cause leading to this artifact is a transient concentration of the blood due to a lessening of its fluid constituents from purgation, excessive vomiting or free sweating. In addition to this a stasis in the peripheral circulation from either organic heart disease or functional depression from profound toxemia, will raise the blood count above the true measure of the patient's anemia.

The significance of the presence or absence of a leukocytosis is, perhaps, the part of this subject that we, as surgeons, are most often concerned about.

Without going into the discussions that have recently arisen on this subject, we can consider the phenomena of leukocytosis as primarily one of phagocytosis, it making no difference whether the toxic materials are directly taken up by the leukocytes or neutralized by a substance formed in part by their activity.

If poisons of certain kinds are in the general circulation, there is ordinarily a general leukocytosis, its grade depending largely on the resisting powers of the individual and the amount and kind of poison.

Sometimes a sudden and overwhelming dose of septic poison will so depress the patient that there is no phagocytic reaction and a leukocytosis does not appear.

Then, too, in prolonged suppurative processes, with free absorption of the septic poison, at first there is an active phagocytosis with a large leukocytosis, but as the powers of resistance of the patient sink the leukocytosis becomes very insignificant, or as time goes on the focus of suppuration may be shut off by nature from the general circulation, and again the number of leukocytes falls.

In a general way, high grades of leukocytosis are most commonly satisfactory signs; while they are due to severe infection, they usually mean good reaction.

Moderate grades of leukocytosis, if the other signs of infection are severe, are, in themselves, suggestive of a bad result; if the other signs of infection are slight, a mild leukocytosis means nothing of itself.

If the origin of the infection is in a part of the body rich in lymphatics and rapid in absorption, other things being equal, the leukocytosis will be more marked. Thus it is that a peritonitis gives a greater leukocytosis than a pleurisy, and why the upper part of the peritoneal cavity, if infected, gives a quicker and more profound systemic infection than the lower.

Of course, in a streptococcus infection, per se, we should get a higher grade of leukocytosis than in a staphylococcus; yet, as we have shown, the degree of leukocytosis is so dependant on the amount

of poison absorbed and the resistance of the patient, that we can form no judgment as to the character of the infection from the blood count.

For years the text-books have nearly all contained the statement that there is commonly a leukocytosis in cancer. On what this is founded we do not know, for any one with any practical experience in this matter must know that such is not the case, a leukocytosis in this condition being very uncommon and does not seem to be influenced by metastasis. Only nineteen out of forty-nine patients, at the German Hospital, suffering from carcinoma, gave a leukocytic count of over 10,000, and only two of these were above 20,000, these two being respectively an ulcerating carcinoma of the breast, which gave a blood count of 31,500 leukocytes, and a carcinoma of the liver with 40,800 leukocytes.

In cases of appendicitis, we cannot depend on the blood count for our indication for operation, for the favorable time for this operation is in the first hours of the attack, when the chief symptoms are those of appendiceal colic and before severe systemic infection has taken place. In these cases we often have rupture of the appendix, or transmigration of organisms so suddenly infecting, in an overwhelming manner, the entire peritoneal cavity, that a leukocytosis is not established, or is very evanescent, owing to the rapid paralysis of the resisting powers of the individual. Or, as the symptoms improve and the leukocytosis falls, we might think that the appendix was becoming normal again, when the truth was that an abscess had only become localized, and no more septic material was being absorbed. If acting on this supposition, we should decline to operate, we should leave our patient exposed to the greatest risk of a secondary outbreak that would be very likely to cost him his life.

We shall be doing much better surgery if we promptly operate on our appendicitis cases, than if we waste time over a blood count that, as is shown by Dr. Da Costa's paper, read before you, is of very little value. In the experience of the author, in cases of salpingitis, even quite moderate grades of leukocytosis (14,000 to 17,000), are indicative of the presence of pus. Yet this is by no means constant, for nature is so well able to care for these cases, that often large collections of pus are present without a leukocytosis, much to the embarrassment of the surgeon who depends upon the blood count alone to show the presence of suppuration.

In cases of obstructive jaundice a leukocytosis is usually, but not always, present, and in our experience seems to be most often due to a local peritonitis around the gall-bladder. In eight out of fourteen cases of obstructive jaundice, due to gallstones, a leukocytosis was present.

Although I have not the data at hand to verify this statement, I will venture the opinion that the most virulent of micro-organisms may inhabit the altered bile of an occluded gall-bladder without giving systemic signs, thus explaining many cases of peritonitis after gall-stone operations, in which the operator, thinking the bile sterile, has allowed it to soil the general abdominal cavity.

Pohl (1), Wilkinson (2) and Boland (3) have done some very interesting work in regard to drug leukocytosis. These investigators have found that

many drugs have the power of producing a quite marked leukocytosis; among these, quinine, the silicylates, antipyrine, phenacetine, pilocarpine, Dover's powder and morphine; all drugs that our patients may have been taking at the time we are called upon to make a diagnosis.

We might go on showing many other instances of surgical conditions in which the blood count is of doubtful value, or, at any rate, disappointing, but we have, we think, said enough to define our position.

We believe that if we have a decided leukocytosis (20,000 or over), after excluding pneumonia, leukemia, etc., we can safely infer the presence of pus. Yet without a leukocytosis we cannot be sure that pus does not exist. We also consider exquisite tenderness, temperature, pulse, and the general appearance of the patient as much more reliable guides than blood count.

Therefore, gentlemen, I wish to say in conclusion: let us have blood counts made on our patients; we have already learned valuable lessons from them and undoubtedly will learn more in the future; but let us not be drawn aside by their still uncertain evidence from the lessons learned by practical experience at the bedside.

COMPLICATED FRACTURES, THEIR DIAGNOSIS AND TREATMENT.*

By THOMAS H. MANLEY, Ph. D., M. D.

of New York

Gentlemen: When requested by my colleagues to participate in this series of evening lectures, I cast about for something on which, from an ample experience, I might be permitted to speak with some emphasis. Therefore, now after nearly twenty years as an interne and assistant surgeon and surgeon to a hospital service in which grave traumas predominate, and wherein I had seen several thousand mechanical disorganizations of the osseous parts, and every conceivable type of fracture, I decided to select for this evening's discourse the consideration of a theme always of dominating interest and importance to practitioners, for of all the serious traumatisms, there are none so common as fractures, broken bones. It has been well said that there is no class of injuries which are approached with greater misgivings, hesitation and doubt, and no one which calls forth a greater degree of knowledge, skill, discernment and judgment, than the diagnosis and correct management of obscure or serious fractures. Time will not permit of a brief survey of the traumatisms of the irregular bones, of the carpus and tarsus, the vertebrae and bones of the face, or the flat bones of the cranium and pelvis; and hence only fractures involving the extremities can be touched on this evening. As a preliminary step, let us glance cursorily at the osseous abode of man, the skeleton, that we may ap-

preciate its mechanism and purposes, and the special functions of its members. We will observe as a preliminary step the position and functions of the extremities. We see that the lower consist of doubly jointed levers, that they stand as double pillars or columns to support the whole body in the standing attitude, and when in action, raise, lower, move or project it. Though these members subservise a highly important purpose, this is insignificant as contrasted with the hands and arms, the mechanism of which, their strength, action, and marvelous execution, stamp man as the monarch of all animal creation. These administer to our every want, provide us with the necessities of life, and enable us to maintain ourselves and others. We need not wonder, then, why a comprehensive and practical knowledge of the traumatic lesions of these appendages of the body is expected of all who exercise the healing art.

Diagnosis.—Now, let us, in this brief study, first consider the symptoms and signs of fracture, in this instance the art of detecting fracture. But I am sure that some may submit, that in a post-graduate course, like this, it will be largely labor lost, as any tyro can have no difficulty in this direction, if he observe a few rules of the text-books, if he note that in every fracture there is loss of function in the limb, that there is visible deformity and a false point of motion when a shaft is involved. The practitioner called upon to deal with this class of injuries, will soon learn that in a considerable number it is a delusion, and occasionally we will encounter instances in which, by no means short of an operative incision, by no way known to art, can some fractures be detected with certainty. It is fortunate that, as a rule, in these obscure cases, accurate, definite diagnosis is not imperative in order to institute appropriate treatment; however, that we may safeguard our reputation, and, besides, for medico-legal reasons, in cases liable to be followed by a civil action, we must exhaust every resource to attain definite information here, which will not inflict injury or be to the detriment of our patient. We proceed to diagnosticate the case of suspected fracture by availing ourselves of the following:

- 1st. A history of the case.
- 2nd. Inspection of our patient.
- 3rd. Posture, attitude, or position.
- 4th. Manipulation, palpation, pressure, torsion, and traction.
- 5th. Narcotic relaxation of the muscular system.
- 6th. The Roentgen Rays, transillumination.
- 7th. The exploratory incision.
- 8th. A consultation.

Now, let us hastily recapitulate, and first, we will begin with an inquiry. A searching history of a case is a most helpful aid; for example, if an elderly person, more particularly a female, has suffered a fall on the hand with resulting loss of power and great pain, we are quite certain of a Colles' fracture, and if, again, one, as the former in age, has suffered a fall on the hip, with loss of power following, we suspect a fracture through the neck of the femur. But we must be cautious here, that the patient, in detailing his case, has not deceived himself, or is striving to deceive us for fraudulent purposes. Not long since a man came to me with a bandage on his

wrist, stating that in the morning he was injured through the neglect of a car conductor in dismounting a street car. The silver-spoon deformity of Colles' was well-marked, but on a very superficial examination, it was evident that the deformity was an old one. The fellow was shown the door. Again, many suffer so little that they suspect nothing more than a sprain, but they have, besides a sprain, fracture, something not uncommon at the wrist and ankle joints.

Inspection.—A critical examination of the limb or body should never be overlooked in any dubious case; by it alone we may frequently differentiate a fracture from a dislocation in thin subjects; before swelling sets in the deformity in displaced fractures is something plainly discernible, though of itself inspection weighs for little.

Posture.—The attitude of the limb or body when injured, with a view of relieving tension, is a great help. In fractures of the non-displaced character, its value is the greatest, notably so when these involve the shoulder-girdle, the neck of the scapula or its apophyses, the outer third of the clavicle, or are in close proximity to, or pass through the anatomical neck of the humerus. In order to be effective, our patient must always be placed on a hard, flat surface, a table if possible. For suspected fractures about the shoulder joint, the head and shoulders are raised, and the arm carried well upward. When the hip joint is the site near which fracture is suspected, we flex the knee on the thigh and the thigh on the trunk. Many times we will succeed in bringing out well-defined crepitus and movement of the fragments by change of posture, something always available, and all the more desirable, as it rarely provokes suffering.

Manipulation, with all that this term implies, gently, skillfully and perseveringly applied in closed fractures, is the most valuable of all aids in their elucidation. It will rarely fail us, if judiciously employed. In some cases, however, its results are not definite at the first examination, but if we flex the limb and let it rest for 24 hours or more, when muscular spasm has passed off, it may often then clearly expose the character of the injury. In all instances, giving a history of a severe sprain, let us search for a fracture, and critically manipulate the nude parts, lest we commit an oversight and damage our reputation by incomplete, superficial work. Five years ago a malpractice suit arose in this city, in which the first physician called was the defendant. The patient, a young actress, summoned the doctor for what she said was a bruise of the knee, from a fall on the floor. The doctor hesitated to expose and critically examine the parts injured. After a week she dismissed him and called another physician, who at once stripped the parts and discovered a fractured patella with three inches of separation. Again it would seem that manipulation will mislead in inexperienced hands. Several instances have come under my notice in which limbs had been braced or splinted for fractures which did not exist; one case being a woman, who was being treated for an intracapsular fracture of the femur. On examination I could find no trace of fracture, but a dislocation onto the dorsum of the ileum. This was easily reduced, and the poor woman spared from being left a helpless cripple. One case in a man, Dr.

Sayre's harness for fracture of the clavicle, the bone being found perfectly normal; and another, the case of a boy, whose foot and leg were bound up in a plaster of Paris dressing for a fracture of both bones; but not the slightest trace of osseous lesion could be found. These were illustrated instances of inexcusable carelessness at the time of examination.

Narcotic relaxation of the muscles we must sometimes resort to, in hyperesthetic conditions of the limb, in children or hysterical women, or in many obscure or doubtful cases, when a diagnosis is urgently called for. When other measures fail, and muscular spasm is extreme, pulmonary anesthesia carried just far enough to obliterate the pain sense will slacken the grip of the muscles quite enough to allow motion of the locked up fragments. In some cases a critical precise examination of a doubtful case is impossible, without this precious resource. A little over a year ago a case came under my care which proved its great value. A gentleman of 40 years sustained a severe injury to his hip joint from a fall. The family practitioner being in doubt as to the character of the injury, called in one of our best-known surgeons for a consultation. It was then decided that the injury was a severe contusion with a resulting arthritis. But the man continued from bad to worse, suffering the greatest torture on any movement of the limb or body. A week after the first consultation, the case was seen by me with the doctor. Now, on a strong table he was placed, and under an anesthetic, creptitus with displacement was clearly obvious. The Roentgen ray, all must concede as one of the most useful diagnostic agents of modern times. Yet in osseous traumatism this mode of photography is by no means free from errors and uncertainties. Except in the hands of an expert, it is quite useless, and even then, the shadowgraph is not infallible. No two of them are quite alike; one may exhibit a sound limb as sundered, and in another, perfect continuity, where the evidence of fracture is unequivocal. With a method so full of vagaries, errors and ambiguities, we must necessarily accept with reserve its revelations, a diagnosis on which alone, in very obscure cases, is certainly not indefensible. The *open incision* involves a surgical operation and has been recently advocated as a means of diagnosis. It is certain that the scalpel will remove all possible doubt, but in the greater number of cases of closed fracture, their recognition is possible by simple methods. Moreover, should infection with suppuration follow, unless special conditions justified it, this sequence might involve us in serious troubles. From my own very limited experience with it, however, under proper precautions, it seems to be a perfectly harmless procedure. Here before you are two patients, who came into my service within the past month, on whom it was employed. You will observe that one is a young man and the other a man advanced in years. The former, ten days before he entered, sustained an injury at the ankle in a brawl. He was first treated for a sprain; having no improvement, he consulted another physician, who was in doubt, and who sent him to my clinic for a diagnosis. At that time the ankle and foot were swollen and edematous, the joint stiff and parts highly sensitive. An incision

three inches long, four inches above the head of the fibula, readily exposed an oblique non-displaced fracture. There was a free discharge of venous blood. The incision was immediately completely closed, and a plaster dressing applied. In the other, though only treated three weeks ago, you will observe that the incision is completely healed. He sustained an injury to the forearm six weeks since. Went to a dispensary and was given a liniment, the arm was bathed and massaged. He was advised to keep up free motion in the wrist and elbow to overcome the rigidity, but this he found was impossible because of the great pain it provoked. On a very thorough examination, we believed that there was a probable fracture near the round head of the radius. Here, again, a free incision was made, when another non-displaced fracture of the radial shaft was discovered. The wound was hermetically sealed and a support applied. In both of these cases the results have been very gratifying, and it would certainly seem that the division of the tense indurated soft-parts exercised a most salutary influence by relieving pressure, by local depletion and favoring reparative processes in the osseous parts, as you will find on examination perfect consolidation of the fragments. We now turn to the last, or, perhaps, what should be the first step, a *consultation* with a practitioner whose knowledge is greater than our own in this type of traumatism. In all severe or doubtful fractures, one should not neglect this; both for the patient's advantage, to divide the responsibility and protect ourselves. If circumstances prevent it, one may send the case to a hospital where his responsibility ends. Having decided on diagnosis, we proceed to the consideration, in outline of the treatment of complicated fractures. And let us, at the outset, distinctly bear in mind that in all fractures, the result of direct violence, the lesion of the bone is but one, and sometimes the least one, sustained by the crippled limb, the main blood-vessels, which sustain the vitality, maintain its nutrition and provide the regenerative elements, may have been mortally crushed, or have sustained various degrees of damage; the nerve cords which animate the limb may have been contused or torn; the muscles never entirely escape, nor the ligaments, in breaks contiguous to the articulations, and hence we may say, in a measure, all severe fractures are more or less complicated. We broadly divide the injuries to bones into two classes, the closed and the open. This nomenclature is much more accurate than the older, of "simple and compound fracture," because, as has been noted, every fracture is compounded, i. e., the so-called simple with the skin unbroken, sometimes is a more serious traumatism than the one attended with exposure by laceration of the skin and displacement of the fragments. Reduced to a brief summary of basic rules, the principles of all fractures involve: 1st, the placing of the limb in a comfortable position. 2nd, we must look well to an unhampered circulation. 3rd, we will reduce the fragments and support the limb. These directions are certainly simple enough, but I am sure you will regard them as inadequate, inasmuch, as I have not emphasized the importance of enforcing the time-honored maxim, to, in all fractures immediately, reduce the fragments and immobilize them. Now, in closed fractures we have

essentially three types: 1st, the displaced; 2nd, the non-displaced; and 3rd, the impacted. This being the fact, it should give us the *raison d'être*, or explain why we should observe this antiquated vicious dictum, in the two latter, or, how can we reduce fragments which are not displaced? And again explain how, in those fractures, followed by impaction, in brittle, articular heads of bones of old people, we can improve on Nature's mode, of at once reducing and firmly impacting the fragments? In the displaced variety there is rarely any urgency for the application of great force, or even immediate reduction. We will note that in some cases of fractures of the leg, the tibial fragment so far resists traction immediately after injury, that Achilles-tendon must be divided to overcome it, and the limb thereby left weak for the remainder of life; but if we simply flex the knee to a right angle, and let the limb rest on a pillow, in 24 hours the spasm will have passed off, the gastrocnemius will have relaxed, and with the greatest ease the end of the fragments will fall into place by slight pressure and there remain. If rest and relaxation are helpful aids in diagnosis, they are especially so in treatment. Can we, or should we, attempt early firm fixation in all fractures? Yes, if we would expose the limb to the peril of gangrene, if we would retard the circulation, delay or arrest repair. Mechanically, we can fix or immobilize anything, but here we are dealing with living parts; moreover, prompt or effective repair is only possible when the circulation is unhampered. Supports we must utilize not so much always to steady the fragments as to prevent joint action when the fragments tend to displacement. Splints are mechanical adjustments; when shall we apply them, and which are the best? In order to answer this question, we may recall, that the osseous frame is made up of connective tissue, and that when traumatized or disorganized, its mode of repair is precisely the same as we witness in connective tissue elsewhere; on division it unites by primary union. For what possible reason then should we employ any description of restraining agent in a non-displaced fracture, when the best splint is none at all, when there is no need of a splint at any time? Several years ago the late Sampson Gamgee demonstrated that when a fracture was non-displaced, or a displaced one was unhampered in approximation, union often occurred in from one to two weeks, and in all these cases there was no callus formation of any description. More recently, Lucas Championniere, of Paris, has entirely dispensed with splints in fractures not attended with marked displacement. This had been his rule in the treatment of a very large number. By this mode, pain is reduced and speedy solid union follows. I may say that this has been my line of practice for several years, the general results being most satisfactory. Prejudice and custom die hard, imitation becomes a habit slow to outgrow. So habituated to mechanical adjustment has the practitioner become, that almost instinctively, as soon as a fracture is detected, he reaches out for a splint, and the people not being educated up to modern advances, will certainly regard him as careless or incompetent, if the limb is not immediately set and bound up with braces. Last autumn a devoted

mother came to me and begged that the house staff would splint her boy's broken leg, as he had been in the hospital ten days, and this was not yet done. She was assured that he would not be neglected. Two weeks later, when he walked out without a limp, the poor woman was amazed, and declared that the lad could not have done so if the limb had been broken, and that we must have imposed on her. Many times after grave injuries to a limb multiple fractures occur, and the parts are so crushed that we are not so much concerned about reduction and complete fixation, as we are as to how we shall preserve the limb at all. We bolster up the fractured limb, relax the flexor muscles, leach, bathe and swathe the parts, we wait the subsidence of inflammation, of plastic union of the fragments, and then splint, not so much to splice the fragments as to hold the joints and support the enfeebled parts. The *open incision*, the operative treatment of closed fractures, has been recommended of late years. Mr. Arbuthnot Lane, of London, has been a warm advocate of it, but the English surgeons do not share his enthusiasm. Recently, Rothschild, of Germany, and Hatch, of Massachusetts, have published brochures on this means of treating fractures, and appear to have had satisfactory results. However, view it in any way we may, the primary incision in closed fracture is full of peril. The traumatized parts possess an enfeebled circulation, their vitality is diminished, and hence are susceptible to septic infection. This radical measure is highly praised by Dr. Hatch, who claims for it that it lessens pain and shortens convalescence. The fracture is first made compound, the fragments adjusted, then closed by suture, and rendered simple again. It would seem an ideal means in femoral fracture, which so generally unite with over-riding of the fragments and shortening of the limb. In two cases of this fracture so treated by myself seven years ago, both patients narrowly escaped death; in one union failed absolutely; ankylosis of the knee with great muscular wasting followed in both. While the greater number of closed fractures yield to safe and simple measures, the cases must, indeed, be few which warrant this sanguineous and dangerous resort. As a conservative measure, after all inflammatory changes have abated, to correct a deflection or deformity, the open incision combined with osteotomy and osteoclasis is utilized with great advantage. This young man's limb illustrates the happy results succeeding, when we divide the non-inflammable parts. Six months ago, it appears, he suffered a very bad fracture of the lower third of the tibia and fibula, the fragments united with so much distortion that the inverted foot presented the sole up and the dorsum resting on the ground, left a hopeless, helpless cripple, with great atrophy of the muscles of the leg, an ankylosed ankle joint, and a swollen sensitive foot. By the free open incision, a complete refracture and osteosection, after two months' treatment, you will observe that he readily walks up and down the aisle without any support, and can stand on one foot quite as well as on the other. But here let it be noted that we operated in healthy tissues, we employed no drain, and secured practically primary union. We hear much about the *ambulant treatment of fractures*, which means moving about daily, to take advantage of exercise, fresh air

and change of surroundings. No one will dispute the advantages of early locomotion, but in practically all fractures of the lower limb, at the time of injury, the body has simultaneously sustained great shock. Here composure and rest in bed are indispensable. In the early stages of fracture of the lower extremities, the horizontal position of the body is essential, but after the first or second week the osseous repair is much facilitated and hastened in the vertical position; the venous turgescence and marked swelling seem rather to accelerate consolidation, and in these fractures we will often observe how union is generally hastened when we remove all splinting, and place the patient on crutches. Of *compound or closed* fractures, time will only permit of a very brief reference. These, with few exceptions, are formidable injuries, often endangering life, or leading up to an amputation. In former times they filled the practitioner with the greatest apprehension, infection frequently occurred, intense inflammation set in, erysipelas developed, or gangrene seized on the parts, destroyed the limb, and often life with it. But of late, it has become quite the established rule to save all these cases in which the circulatory current has not suffered mortal damage at the time of injury. By the aid of antiseptics, anesthetics, and aseptic precaution, we first endeavor to preserve the limb in the best shape we can. By resorting to modern osteoplastic methods, as taught by the late, great Ollier, we now restore to usefulness thousands of limbs which formerly went to the amputating table. Our next lecture will be devoted to a consideration of this class of fractures.

In conclusion, gentlemen, permit me to make a plea for practitioners treating more fractures at home; keep them at home. They constitute an interesting class, and are amply remunerative. Stop this demoralization of the people, of forcing on them your service for nothing. If you feel you are incompetent, then take a post-graduate course or several of them in some institution where this important branch of surgery provides ample opportunities and facilities for instruction.

PITYRIASIS VERSICOLOR, WITH SPECIAL REFERENCE TO ALLEN'S IODINE TEST.

By JACOB SOBEL, M. D.,

of New York.

Dermatological Assistant at the Good Samaritan Dispensary;
Member of the Manhattan Dermatological Society, etc., New York.

Among the cutaneous parasitic diseases of the adult, none is more frequent and yet none more overlooked than that of pityriasis versicolor or chromophytosis. Owing its existence to the lodgment and proliferation in the superficial cutaneous layers of the microsporon furfur, it appears mainly on the surfaces hidden by the clothing—chest, back and abdomen—in the form of yellowish, brownish, reddish, or chamois-colored furfureous patches of various shapes and sizes, which produce but slight subjective disturbance, and which give a very characteristic reaction when painted with various iodine solutions, particularly Lugol's solution. It is mainly because these patches are so small and so light in color in the very early stages, that they es-

cape the notice of both patient and physician. Apart from a mild degree of itching, the constitutional disturbance is *nil* or in inverse proportion to the amount of fungus present. These patients seek treatment mainly for esthetic reasons or because they fear that the spots are indicative of liver disease, and, indeed, they are frequently referred to as "liver spots." From one text-book to the other various premises have been handed down with regard to the parts of the body involved and the predisposition of certain patients. The most common statement met with is that the disease spares the parts exposed to light—that is, the face, hands and neck. On this fact all authors practically agree. Closer observation, however, and the aid of Lugol's solution have served to disprove these time-honored "axioms." Time and again have I been able to demonstrate the existence of the eruption upon the front and back of the neck, at the angle of the jaw and even upon the side of the face as high as the forehead. It is quite true that in many cases only a preliminary staining with Lugol's solution served to bring into relief the seemingly hidden lesions. These areas when painted with the solution appear of a deep mahogany or very dark brown color, which shows itself in marked contrast to the surrounding tissue. We may note from this test not only the existence of the disease, but also its severity and retrogression, for the more active the disease the darker will be the stain; in the declining stages the lesions take up the stain but faintly. This test is of such marked value for class-room demonstration, that it is surprising it has not been more generally adopted by teachers. I cannot say that the test would be of especial value in differentiating this disease from others of a truly or presumably parasitic nature, viz.: disseminated ringworm, pityriasis rosea, mycotic eczema, because they all react to the iodine applications, but it certainly excites a marked suspicion of the parasitic nature of the disease under diagnosis; for if the test be applied to other conditions of a desquamative character, such as seborrheal eczema, dermatitis, scaly syphilide, exanthemata, etc., it will invariably fail, in that while the cast-off epithelium will take up the stain to a mild degree, *there is no markedly positive reaction.* Though Gottheil, in his "Illustrated Skin Diseases," joined the majority in saying that the "face, palms and soles are always free," he at the same time gave the death blow to the statement that the palms are never affected, in the publication of a very typical and unique case (*Medical Record*, July, 1899). For a long time it was supposed that the disease bore some relation to phthisis on account of the great number of cases found in subjects of this disease. That they are frequently attacked is quite true, but that pityriasis versicolor occurs chiefly in such patients is very questionable. Its more frequent discovery in phthisical subjects is due to the fact that this class expose their chest for examination more frequently than others, and the chromophytosis is discovered incidentally. No class or age is exempt, though children and very old people are rarely attacked. I have never seen an instance in those over 55 and children under 15 years. Such cases have been recorded, however. Any disease or condition which produces hyperidrosis offers by reason of this symptom a predisposition to the growth of the fun-

gus. Though parasitic in its nature, it is generally conceded that the disease is not hetero-inoculable, no positive case to my knowledge having thus far been recorded. Max Joseph reports an instance in which it appears that the husband using the same bath-tub, towel and soap, infected his wife. Only recently I observed six cases in one family, a condition strongly suggestive of contagion. The treatment of the disease is apparently simple, any desquamating and penetrating agent, such as hypsulphite of sodium, B naphthol, sulphur, resorcin, salicylic acid, etc., effecting a cure. Treatment must be thorough and persistent; to limit one's self to the use of exfoliating measures, which simply remove the uppermost layers, will result in dismal failures. As the origin "of each patch is peri- and perhaps intra-follicular," the penetrating agents must be added if we will prevent recurrences. To prevent renewed outbreaks is not always an easy matter. As long as any vestige of the disease remains another attack is assured. There can be no question that one important cause of recurrence will be found in the failure to treat a region hitherto overlooked—the suprapubic region. Here, as Dr. Allen has pointed out, numerous patches may exist in their efflorescence, and yet owing to the covering of hair entirely escape recognition and treatment. These patches serve as sources of renewed contagion and the disease breaks out afresh. In men as well as women, these patches are often so small as to be brought into view only by the application of the iodine test. It has seemed to me that pityriasis versicolor in the suprapubic region is at times attended with more itching than that of the rest of the body. This circumstance gives rise to scratching and the carrying of the causative agent to other parts of the body—autoinoculation, as it were. As a result of experience my conclusions are: (1) The old theory that only hidden parts are affected is no longer tenable. (2) Allen's iodine test is of marked value not only for class-room demonstration and for bringing into relief pale and hidden lesions of pityriasis versicolor, but also for differentiating parasitic or presumably parasitic skin affections from those of a non-parasitic nature. (3) Recurrences are in the main due to the overlooking and non-treatment of the suprapubic region and to the use of desquamative agents to the exclusion of penetrating ones. Both must be combined if a cure is desired. (4) Phthisical subjects, while affected in great measure on account of the hypersecretion of sweat, do not form the greater part of these patients. It occurs in all degrees of health and disease, a marked hyperidrosis, however, predisposing towards it. (5) Children and the very old are occasionally, though rarely, attacked. (6) It may occur in all shades from a very light pink to almost coal black (pityriasis nigra), the color being influenced by the condition of cleanliness, the circulation of the skin, the occupation of the patient, and the color of the underclothing.

THE BICEPS TENDON JERK IN LOCOMOTOR ATAXIA

By MOSES BEHREND, M. D.,

At the suggestion of Dr. Burr and under his guidance, I have studied the biceps tendon jerk in 29 cases of tabes. Frenkel, in the July, 1900, number

of the "Deutsche Zeitschrift fuer Nervenheilkunde" states that he has come to the important conclusion that the absence of the tendon reflexes in the upper extremities is a constant symptom of tabes; and that this is even more constant than the absence of the patellar reflex. He says that it is not only constant in the medium and severer cases of the disease, but also forms one of the earliest signs of tabes in the severest, less severe and medium cases, where the ataxia shows itself in its various grades; not one case has been observed in which the reflexes were present in the upper extremities. The above conclusions were reached by him from an examination of several hundred cases.

A table of 23 cases is given by him in which the triceps reflex was present in 5 cases and 3 in which it was present in one arm and absent in the other. This appears to be a contradiction to the paragraph above quoted in full. It is hard to realize that such statements should be made, and especially since he repeats the statement in various parts of his paper that the reflexes are constantly absent in the upper extremities.

Out of 29 cases of undoubted tabes which I examined, the biceps tendon jerk was present in nine and the triceps tendon jerk was present on both sides in two patients and present on one side only in two others. In the two cases in which the triceps tendon jerks were present on both sides, the biceps tendon jerks were absent on both sides in one and preserved on both sides in the other. In one case the biceps tendon jerk was present on both sides with the triceps tendon jerk present on one side only; in another the triceps tendon jerk was present and the biceps tendon jerk was absent on the same side; the reverse was true in the other arm.

The muscle jerks of the arms were present in all the cases and in various degrees of excitability. The muscle "hump" always appeared upon percussing the muscle. The duration of the cases ranged from one to 25 years.

Some interesting results were obtained in examining these cases for sensibility to all forms of stimuli; the relation of the reflexes to the degree of ataxia and the severity of the shooting pains. Generally, it may be said that in those cases in which the biceps tendon jerk was absent ataxia was more marked in the arms, but there were a few exceptions. Of 17 cases in which the biceps tendon jerk was absent, marked ataxia existed in the arms of 11, while in the remaining six ataxia of the arms was only slight. Of the latter two were of the ocular form of tabes. In this variety we have as a rule the ataxia lessened, therefore I believe they should be considered as a separate class. One case of ocular tabes is in a colored man; he is not, however, a full-blooded negro. One of the six above referred to has had locomotor ataxia for the past 25 years and the ataxia of the legs is very marked, the patient being unable to walk.

For the sake of comparison let us consider the relation of the arm to the leg ataxia. In three of the six cases in which there was slight ataxia in the arms, ataxia of the legs was marked, while in the 11 cases referred to above in which the legs was

marked in 10 and slight in one. The latter illustrates the occurrence of hemiplegia in tabes. The history of the case is as follows:

Patient is Frederick F. Age 62. Denies syphilis. In 1892 patient had shooting pains, some disturbance when walking in the dark, followed by a sensation of velvet on the soles of his feet while walking. A couple of years later he complained of girdle pains which were not constant. In 1897 after his symptoms had slowly progressed he was suddenly unable to open his left eye. The patient did not have any other paralyses. At the present time the right foot is dragged a little in walking and the gait is somewhat staggering. The patient is a well-nourished male, average height, iron gray hair and beard. Sensation for all forms entirely normal. The knee jerks are present on both sides, more marked on the right leg. The biceps tendon jerks are absent in both arms. The triceps tendon jerks are present in both arms. Achilles tendon jerks are marked on both sides. The Babinski reflex is present as is shown by stroking the sole of the right foot, the great toe extends, the others flex with separation. On the left foot there is marked flexion of the small toes with no movement of the great toe. The patient sways some with eyes shut. Pupils do not react to either light, convergence or accommodation.

The Babinski reflex was present on both sides in another case in which the knee jerks were lost in the absence of the hemiplegic state. The history of the case is as follows:

Patient is Ludwig. Age 61. He is so dull and stupid that we are compelled to rely solely on the physical examination. He is somewhat emaciated, skin is bronzed; gait is ataxic: sways considerably with eyes closed. Argyl-Robertson pupil is present. Knee jerks are absent. Biceps tendon jerks are present on both sides as are also the triceps tendon jerks. Achilles jerks are absent. Ataxia of the arms and legs is marked. Upon stroking the soles of the feet marked extension of all the toes occurs.

In nine cases the biceps tendon jerk was present. Ataxia of the arms was very marked in two. In one of the latter atrophy of the muscles of the hand was seen, with changes in the joints similar to those found in rheumatoid arthritis. The right knee jerk was absent, the left was lightly present. In the remaining seven ataxia of the arms was very slight. One has had tabes for 22 years. He has marked ataxia of the legs, relaxation of the ligaments around the knee joints, causing retroflexion. Of the nine cases in which the biceps tendon was present, ataxia of the legs was marked in five.

Absent biceps tendon and knee jerks were constant in those cases having arthropathies. The trophic changes comprised three dislocated hips, one dislocated shoulder, two retroflexed knee joints and a tabetic foot. The patient having the latter has never been reported. Her history is as follows:

Alice B. Aged 59. Syphilis denied. Her family and past medical history are unimportant. The patient says she was perfectly well until five years ago, when after exposure she had a chill. Since then she has been subject to pain in the joints. She was afraid to walk; she would stagger and fall if unsupported. Two years ago her right shoulder and left hip were dislocated without the history of an accident. The patient is a very well-nourished female, very nervous disposition, very irritable, becomes easily flustered upon slight provocation. The left pupil is greatly dilated, eyes are prominent and convergent. Irides do not react to light, accommodation or convergence. A condition of double ophthalmoplegia is present. She sees very little and cannot distinguish objects. The right shoulder is very prominent, not painful and can be protruded at will in various directions. Marked lordosis of the spine is also present. The reflexes are all absent, ataxia of arms and legs is well marked. Sensation is impaired; pain, tactile and thermal losses being found only in areas on the legs. After-sensations are found in the legs. A feeling of pricking and sticking is felt from three to five minutes after the aesthesiometer is used; the discomfort being greater than

when the stimulus is applied. The left foot is swollen and edematous, the toes are turned slightly downward and there is complete foot drop.

Sensation was normal in six of the nine cases in which the biceps tendon jerk was present on both sides, and in eight of the seventeen cases with the biceps tendon jerk absent.

Two of the eight cases above mentioned were of the ocular type. Sensation was also normal in two of the three cases in which the biceps tendon jerk was present on one side and absent on the other; while in the remaining one pain and thermic sense were diminished on the side in which the biceps tendon jerk was lost. As is usual in locomotor ataxia, deranged pain sense was almost constant. In one case hyperaesthesia existed in the arms with a large biceps tendon jerk.

Astereognosis was complete in four cases and partial in three others. The biceps tendon jerk was absent and all were markedly ataxia in the arms.

The sense of position is lost only in those cases showing marked ataxia. One exception is found in an advanced case. He is a blind colored man, in whom the left hip is dislocated, together with such relaxation of the ligaments of both hips as to enable him to throw his feet far above his head and with the knees touch his chest. The loss of the sense of position occurred in 11 cases in only one of these is it lost in both arms and legs.

The shooting pains of locomotor ataxia do not seem to have any relation to the degree of ataxia. Nine cases in which the biceps tendon jerk was absent, were devoid of shooting pains in the arms; of these five showed marked ataxia, while the pains were present in nine others, with the biceps tendon jerk lost. Marked ataxia was found in eight of these. In the nine cases in which the biceps tendon jerk was present on both sides the characteristic pains were found in two, while one had slight shooting pains in the arm in which the biceps tendon jerk was present and severe pains on the side in which the jerk was absent.

The loss of weight sense was present in the most advanced cases and occurred in only two cases. Ataxia was very marked in both of these. One of the patients was unable to recognize a weight below eight ounces in either hand. The most advanced, and naturally the most ataxic case in the hospital was unable to recognize a weight below one pound in the left hand and two pounds in the right hand. This patient has had the symptoms of tabes for ten years. He is unable to walk and he has also lost nearly all of his teeth since the onset of the disease. The conclusions to be drawn from these observations are:

1. That the ataxia in the arms is, as a rule, more marked when the biceps tendon jerk is absent.
2. That the ataxia of the arms is usually marked when the same is found in the legs. In these the biceps tendon jerk is absent.
3. That in the presence of the biceps tendon jerk with slight ataxia in the arms, ataxia in the legs is invariably well-marked.
4. That sensation is usually normal in those cases with normal biceps tendon jerk.
5. That the sensory losses are usually found when the biceps tendon jerk is absent.

6. That arthropathies are only found in the advanced cases.
7. That astereognosis is only present in the markedly ataxic.
8. That the loss of the sense of position is almost constant in the advanced cases of tabes.
9. That the shooting pains in the arms do not bear any relation to the degree of ataxia.
10. That the marked ataxics seldom show the loss of weight sense.

11. That the intensity of the symptoms are not dependent on the duration of the case, but rather upon the extent of the sclerotic process. For example, I saw one of my patients who has had tabes for the past 22 years sitting on a railing with the feet resting on a bench and balancing himself well. Another striking point is the selective power of the pathological lesions. We find that the biceps tendon jerks are present in three patients on one side and absent in the other. We can explain this by assuming that the degeneration has limited itself to one side of the cord. In those cases in which the biceps tendon jerks are absent, the sclerosis probably extended to the cervical region, but it is not to be forgotten that this reflex may be absent in normal individuals.

BERLINER KLINISCHE WOCHENSCHRIFT.

February 25, 1914.

1. A Hitherto Unknown Form of Atresia of the Uterus. LANDAU.
2. Demonstration of an Aortic Aneurism Which Gave Rise to the Symptoms of a Mediastinal Tumor. EWALD.
3. The Application of the Phonograph in the Pathology and Treatment of the Voice. FLATAU.
4. The Disposal of City Sewage. GAERTNER.

1.—Landau reports several interesting cases. A woman of 40 had had menstrual disturbances every four weeks from her 12th year, without, however, any loss of blood. Operations performed in the 18th and 23rd years were without result. She had suffered from frequent attacks of inflammation in the abdomen, that had rendered her incapable of working. A vaginal examination showed a huge fornix and cervix with the evidences of a tumor. At the operation this was found to be an enlarged uterus filled with blood, and there were also hematosalpinx of both sides, and alterations in the ovaries. The cervix of the uterus was found to be replaced and the canal occluded by a large tumor, that, upon histological examination, proved to be a mesonephron form of obstruction of the cervix that has not hitherto been described. The second case, a woman 30 years of age, had had similar symptoms and at the operation both tubes were discovered distended with blood, and there were changes in the ovaries. As the pains were not relieved by a bilateral oophorectomy the uterus was opened and some blood evacuated. In discussion of the pathogenesis of this condition, Landau believes that it is due to an embryonal hyperplasia of the lower portion of the Wolffian duct; although he admits that it is possible that there was a bacteriological element in the production of the hematosalpinx. [J. S.]

2.—Ewald reports the case of a woman 43 years of age, who shortly before examination noticed shortness of breath, swelling of the face, and of the right shoulder. At the same time there was distension of the veins on the whole right side of the upper part of the body, some difficulty in swallowing solid food, and as a result almost complete anorexia and loss of flesh. When examined it was found that the face, neck and hands were dark blue in color, the head was held to one side, and upon the thorax and abdomen the veins were prominent. Upon examination with the Roentgen ray a tumor was discovered lying above and to one side of the heart. It did not appear to pulsate, nor have any of the other characteristic signs of aortic aneurism. The heart was not enlarged. There was no murmur over it, nor over any of the large vessels. The

pulse was apparently normal. Dullness was found over the sternum, and from the right clavicle to the 3rd rib. Otherwise the lungs were normal. The patient died about 3 weeks later in an attack of severe dyspnea. At the autopsy a sacular aneurism, about the size of a fist, arising from the ascending portion of the aortic arch and filled with clots, occupied the position of dullness. This had almost occluded the superior vena cava. It had also compressed the trachea, causing partial erosion of its wall, and slightly compressed the esophagus. The inferior vena cava was not involved. In regard to the distension of the superficial veins of the thorax and abdomen, Ewald believes that a collateral circulation with the current downward is necessarily established whenever the superior vena cava is occluded. He does not believe that it is clinically possible to distinguish the direction of the blood current. [J. S.]

3.—Flatau believes that the phonograph is valuable for the study of the pathology of the disturbances of speech, for the demonstration and control of the results of therapy, and for the purpose of clinical and physiological instruction. He demonstrated in the lecture different phonograms from the voice of the same person taken before and after the removal of various swellings in the naso-laryngeal tract. He calls attention to the fidelity with which the curious forcing tone due to slight stenosis of the larynx, is reproduced. The ordinary apparatus requires few modifications. The cylinder may be driven by clock-work or by an electric motor. The best cylinders are probably derived from America and those that have been used several times give the clearest records. On account of the fragility of these records it is desirable to take as many as possible of each interesting case. The maximum number is probably six. Copying is unfortunately at present impossible. [J. S.]

REVUE MEDICALE DE L'EST.

March 15, 1914. (Volume 33, No. 6.)

1. The Treatment of Congenital Dislocation of the Hip. R. FROELICH.

1.—In the past five years, Froelich has treated 31 cases of congenital dislocation of the hip. Successful treatment depends upon radiography. Dislocation of both hips occurred in 15 of his cases: on the right side alone in 10; and on the left side alone, in 6. 26 cases were found in girls. Congenital dislocation of the hip had already appeared in the family in 5 cases; and 3 of these children were tubercular. Hernia existed only in two cases, for one of which the operation for radical cure was done four times, with success at last. In all but four cases the congenital dislocation was due to a congenital malformation. In 4 cases Froelich believes that it followed infantile paralysis. This was confirmed by radiographs in 13 cases, whose measurements have been tabulated. As a rule they grew less lame during 10 years, but the limping became aggravated after 15 years, and was always worse after an illness. In boys it grows rapidly worse, much worse than in girls. The treatment will depend upon the condition seen in the radiograph. Operation will be indicated in most cases, however. Exceptionally, a new joint will form by itself, and should not be disturbed. Operation is most successful between the second and fourth years. Over nine years the bloodless operation will not be possible. Froelich employs the bloodless Paci-Lorenz operation, with the Lorenz after-treatment. The result in 8 cases, out of 28 cases operated, was perfect. Fracture of the upper third of the femur occurred once. Froelich advises operation, but the good results from operation will only become apparent from two to three years afterward. [M. O.]

Orthostatic Albuminuria.—Nivière, before the Medical Society of the Paris Hospitals, (*Bulletins et Memoires de la Société Médicale des Hôpitaux*, 1914, No. 6) reported a case of albuminuria which lasted six months, in a young man of 20. For 5 years he had been troubled with dyspepsia. He had scarlet fever when 7 years old. Examination showed a movable right kidney. There was one gram of albumin to the liter of urine. A flannel binder was applied at once, after which neither morning nor evening urine contained albumin. When, however, the binder was forgotten or not tightly applied, albumin reappeared. He has wholly recovered, and is in better health than ever. Nivière believes that the albuminuria was due to mechanical causes, which disappeared when the abdominal viscera were kept in place. [M. O.]

\$3.00 PER ANNUM

Mr. Rockefeller's Gift.—We learn that Mr. John D. Rockefeller is about to establish in New York City an institute for the promotion of original medical research. It is reported that he has placed at its disposal the sum of \$200,000. This is not an endowment, but rather for immediate expenditure. It is announced that the institute is to furnish facilities for original investigation, particularly in such problems in medicine as hygiene and the treatment of disease. While it is to be established in New York City, it is apparently not to be a purely local affair. The Board of Directors includes the names of well-known pathologists and medical scientists not only of New York, but of Philadelphia, Boston and Baltimore. It seems that this institute is to be without any organic affiliation with existing medical schools. At least we judge this from statements which we have read in the newspapers. Thus, the names of specialists connected with the University of Pennsylvania, Johns Hopkins University, Columbia University, Harvard University and the Bellevue Hospital Medical School are mentioned. This feature of the plan strikes us as being not without its advantage. There is no reason why an institute for original research in medicine should not be entirely independent of any existing medical school. The idea is, of course, somewhat of a novelty, but with money to back it, it can no doubt be embodied in a successful way. It seems that the new institute is to be somewhat on the model of such establishments as the Koch Institute in Berlin and the Pasteur Institute in Paris. If it is well endowed and its scientific work conducted by learned experts and scientists drawn from various parts of this country, it doubtless will have a great future, and the fact that it can draw upon the best workers and teachers without regard to the schools in which they teach will, perhaps, be an advantage. The difficulty, we should think, would be to secure active work in New York City from men who are located in other places. This, perhaps, may not be entirely within the design, as the names announced are simply of those who will constitute the Board of Directors. It is doubtless true that in an ordinary college routine too much valuable time is taken up in teaching that might be

spent, and must be spent, upon original work. In other words, the two interests, teaching and original work, do not by any means necessarily go together, as seems too often to be the idea in this country.

The Study of Tropical Diseases in the Philippine Islands.—We have received a copy of the medical circular on tropical diseases issued from the office of the Chief Surgeon of the Division of the Philippines. Under the authority of the Surgeon General of the Army, this circular was ordered to be prepared by First Lieutenant R. P. Strong, Assistant Surgeon, U. S. A., with a view of presenting to the medical officers on duty in those islands a concise report of the diseases with which they have to deal. This is a most satisfactory evidence of the care now being taken by the United States Government to advance not only the cause of medical science, but also the welfare of the troops in those distant possessions. Dr. Strong has prepared a series of interesting reports, or tracts, on some of the infections which cause intestinal disorders especially. These disorders, we judge, are particularly rife in all tropical countries.

The ameba dysenteriae is described minutely. It was encountered in the stools of nearly 500 cases of dysentery. The lesions were such as are usually described in amebic dysentery. The parasite was found in the mucosa, sub-mucosa, and intermuscular septa. These amebæ were also found in 18 abscesses of the liver; on two occasions these abscesses had penetrated the lung cavity, and the parasites were found there. They are pathogenic for cats, which can readily be inoculated with them through the rectum. Great stress is laid upon the importance of amebic dysentery as a tropical disease. It may be overlooked until it has established a firm hold upon the victim. Repeated attacks of diarrhea and intestinal catarrh should excite suspicion, and the case should be treated radically. Dr. Strong appears to rely upon the local treatment with high quinine enemata. He also distinguishes between this ameba and the ameba coli, the latter of which, he thinks, is apparently harmless.

We cannot dwell in detail on all the parasitic dis-

eases mentioned by Surgeon Strong. In an interesting paper on the infusoria, he describes the *balantidium coli*, which is also a cause of intestinal disease. The flagellates are also described. These papers show clearly how important it is nowadays for the physician to be also a naturalist. The cestodes, or worms, are about the same in the Philippine Islands as here at home. The common forms are the *tænia saginata* and the *tænia solium*. The *echinococcus* is not common. The troops have been much infested with the common lumbricoid worm. One of the most interesting of Dr. Strong's papers is the one on filaria. He shows the relation of this infection to the mosquito, which may act as intermediate host. Not the least of the soldiers' troubles in the Philippines is caused by a small leech, which works its way into the skin even through the shoe laces. As we have already said, this paper is an interesting evidence of the good medical work being done in the Philippine Islands under the auspices of the United States Government.

The Relation of the Art and Science of Surgery.—

An interesting paper has been written by Dr. John A. Wyeth, of New York, on "The Value of Clinical Microscopy, Bacteriology, and Chemistry in Surgical Practice," being his oration on surgery before the American Medical Association at St. Paul. In this address, Dr. Wyeth shows the great advantage, in fact, the absolute necessity, for every one who does surgical work to understand thoroughly the science as well as the art of his branch, and he reviews very carefully what bacteriology, chemistry and the microscope have done to make surgery an exact science. He points out very clearly how impossible it is for one to be a thorough surgeon who does not understand and appreciate the work done in the laboratory, and tells us that this knowledge is as necessary as the practice of a perfect aseptic technique. The author shows a wonderful familiarity with the various methods of examining the blood, urine, sputum, etc., when it is remembered that his life as a surgeon and teacher is a very busy one, and what he has also done to advance the practical side of surgery. Although all good surgeons are not agreed on these subjects, one has but to refer to what the blood count alone has done to aid in surgical diagnosis and to direct surgical treatment, to concur with Wyeth that it is the duty of every surgeon, it matters not how busy he may be in the operating room, to familiarize himself with the science of surgery and to keep himself informed of the great advances made in laboratory methods. These advances all have a very practical bearing on his success as a life saver. Too often are operations recommended and performed when, if we had been

more careful in our examination of the supposed healthy organs as well as those diseased, the operation might have been avoided and perchance an operative death prevented. Not infrequently do we discover after operation that our patient is suffering from some lesion of the kidney or condition of the blood, which, if known previously, might have greatly altered our treatment. The wise and thoughtful advice of Wyeth cannot be too heartily commended to those doing surgical work.

The Treatment of Chronic Ulcer of the Stomach.

—Those of our readers who are interested in either general medicine or surgery must have read with pleasure and profit the excellent paper by Mayo Robson, in a recent issue of the *Journal*, on the surgical treatment of chronic gastric ulcer. One who is familiar with the work done by Mr. Robson, feels that what he writes on this subject must be authoritative, for few individual surgeons have had the extensive experience in operations upon the stomach and neighboring viscera which he has enjoyed. Although one cannot always agree with some of his statements, and occasionally may feel that the author is too radical, yet on the whole his article on this interesting condition impresses the reader as being from the pen of one who thoroughly understands the subject and who has given it the most careful thought and consideration. He urges upon the practitioner the great necessity of instituting early the most rigid medical treatment for acute gastric ulcer and of keeping this treatment up for a number of weeks after pain and other symptoms have subsided. He shows us very plainly that subsidence of symptoms does not mean that the ulcer has entirely healed, but only that the healing process has become established. Chronic ulcer usually follows a number of relapses after lax and ineffectual medical treatment. Robson shows, too, the greatly lessening mortality brought about in all surgical work upon the stomach during the past few years, and proves that in the treatment of gastric ulcer this mortality is much less than in cases in which medical treatment alone is depended upon. The paper is a long one, but every general practitioner, as well as every surgeon, can derive benefit from its perusal.

The Proposed Removal of the Almshouse.—

The city of Philadelphia erected the present buildings occupied as Almshouse, Hospital, and Asylum for the Insane, in the early thirties, and five wards only have been added to the structure in all these years. The city in the meantime has grown from a provincial town to be one of the great cities of the world, and the original plan of grouping the sick, the paupers, and the insane beneath the same roof and

jurisdiction, has proven sadly inadequate. Despite the best energies of a judicious management and an able medical staff, the death-rate in the institution is admittedly unnecessarily high, owing to the unfavorable conditions, such as the overcrowding and the old infected buildings which were built before the day when sanitary construction became so important a factor. There is no division of opinion among the profession or among those interested in public charities as to what should be done. There must be a speedy separation of these three great departments of city charities. Modern treatment of the insane exacts the proper conditions under which these unfortunates shall be treated. In the light of present-day knowledge, an almshouse must be built with due regard to light and air, and there must surround it a number of acres of land, the tilling of which may occupy the minds and bodies of these unfortunates. The Philadelphia Hospital should be a representative institution of its kind, built with properly constructed buildings, and of sufficient size to prevent the lamentable overcrowding which at present exists, and to enable its patients to secure the most improved hygienic surroundings, as well as the best medical treatment. There is also great need that the Philadelphia Hospital be separated entirely from the Almshouse, so that the stigma of pauperism may not fall upon its patients. On last Monday evening the Council Committee on Charities and Correction held a public meeting to discuss this subject, which was attended by a large and representative gathering. There was a consensus of opinion as to the necessity of making the changes mentioned above, and a resolution was offered and passed unanimously directing the Board of Charities and Correction to decide upon suitable sites and to present their report to the City Council. We trust that every medical man will interest himself personally in emphasizing the great necessity for these proposed changes.

Hygiene and Sanitary Science.—Dr. George M. Kober, Professor of Hygiene in the Georgetown University, delivered before the 52d annual meeting of the American Medical Association at St. Paul this week, the annual oration in State Medicine on "The Problem and Tendency of Hygiene and Sanitary Science in the Nineteenth Century." In view of the fact, as Dr. Kober has pointed out, that hygiene is not an independent science, but a correlation of the teachings of physiology, chemistry, physics, meteorology, pathology, sociology, epidemiology, and bacteriology, it is not surprising that the progress of this branch has been phenomenal. To emphasize that this science is not of modern origin, he alludes to the hygiene of the Greeks and Romans—the care

they paid to their water-supplies and bathing facilities, and the special attention paid to the physical culture of their youth.

The greater portion of his address is confined to the discussion of the progress of sanitation in the United States, referring to the duties of health boards, quarantine regulations, the results derived from improved water-supplies, the value of pure food and drug legislation, industrial, rural, and school hygiene, and the management and control of infectious diseases. The enactment of proper sanitary legislation and the education of the public in regard to the nature and causation of infectious diseases, will be important advances in the solution of the problem of prevention. In this connection of special interest is the statement that enteric fever, a so-called preventable disease, causes an annual total loss in the United States of \$185,000,000. Dr. Evans has estimated that the annual loss sustained from tuberculosis in the United States is \$574,000,000. However, the mortality statistics of 1890 and 1900 show a marked decrease in the death-rate from typhoid fever and consumption, and the American medical profession has much to be proud of in the century's progress in preventive medicine.

In this important contribution to medical literature we cannot fail to be struck with the development of modern hygiene, especially when we reflect upon the ignorance and superstition that prevailed in former times. With the ever-increasing means of observation and the more intimate co-operation of the profession throughout the civilized world, further progress and perfection in hygiene are to be expected with confidence.

The Cause of Cancer.—In view of the great interest that has recently been excited by Gaylord's article regarding the parasite of cancer, some recent work performed in the laboratory of Professor Wyszokowitsch may be of interest. De Meser, having observed some lycopodium spores in the interior of a cancer of the skin, which had evidently been derived from the powder that had been used in dressing it, called attention to the extreme difficulty of distinguishing between parasitic bodies and particles of foreign material absorbed from the surface. Konstantinowitsch having become interested in these cases, endeavored to determine just what effects different bodies, such as the spores of lycopodium, would produce when injected into the skin. He found that, as a matter of fact, they produced growths not dissimilar from ordinary granuloma, containing epithelioid and giant cells. This is only an additional illustration of the very important part that mechanical conditions play in the development of tumors, an element that was recognized nearly half a century ago by Virchow, and which, in the

eagerness to discover a parasite or to explain their origin as a result of some disturbance of the embryological mechanism, has been again and again forgotten. The experimental work to be done with regard to tumor formation is very considerable, and it is strange that pathologists have neglected it so much.

A Judge's Opinion on Osteopathy.—We fail to see of what use it is to pass a law for the regulation of the practice of medicine and surgery when any country judge can deliberately misinterpret the act so as to render it inoperative. Recently, in Venango County, Pennsylvania, the judge in the Common Pleas Court rendered an extraordinary decision in a case involving the legal status of osteopathy; and the grounds upon which his decision was based were as fair a sample of judicial sophistry or word-splitting as it has been our lot to see. Judge Criswell declared that the "practice of medicine," as defined by the act of Legislature, means the treatment of disease by the use merely of drugs, and that any other kind of treatment is not the "practice of medicine." Therefore, as osteopathy does not treat disease by the use of drugs, it is not a practice of medicine within the meaning of the law, and its practitioners can have full swing in the State of Pennsylvania without a license and without let or hindrance.

It is difficult to characterize such judicial wisdom as this. The respect which we owe the bench is severely tested by the utterance of such Dogberry opinions. According to Judge Criswell, a physician is simply a drug dispenser. What a surgeon is, in his opinion, we do not pretend to know. To keep within the meaning of the law, the doctor must prescribe pellets. If he attempts to practice in the broad field of preventive medicine, of hygiene, of dietetics, of hydrotherapy, of climatology, of suggestive therapeutics, of psychiatry, of obstetrics, of ophthalmology, and of three-fourths of the whole field of surgery (i. e., so far as he practises in these fields without drugs) he is no doctor. Ergo, any ignorant charlatan can enter these fields, and, so long as he gives no drugs, he is not required to have a license under the laws of Pennsylvania! Fortunately, it is sufficient merely to present Judge Criswell's opinion in order to show its foolishness. We trust the Supreme Court will reverse his decision and save the Commonwealth from such stultification.

A Mayor's Objection to Vaccination.—The Honorable Tom Johnson, of Cleveland, Ohio, announces to the world that he does not believe in "contaminating a man's blood with poison," and he declares that "no doctor shall pump any virus" into him. These bellicose utterances of the Honorable Tom Johnson, Mayor of Cleveland, were called forth, ac-

cording to the *Plain Dealer*, by the prevailing epidemic of small-pox in that city. We do not know what power the Mayor of Cleveland has to control the vaccination problem in the State of Ohio, but we call attention to the figures supplied by the *Public Health Reports*. From January 1st to May 11th there had been 899 cases of smallpox in Cleveland and its neighborhood. According to these figures an adverse fate has been "pumping the virus" of smallpox into the citizens of Cleveland at a high rate of speed. If the Honorable Tom Johnson is to have his way in that town, it is highly probable that a great many more Clevelanders will have their blood contaminated with the poison of smallpox before the epidemic is ended. It is deplorable that in this country a street car magnate who happens to get himself elected Mayor, should thus assume to speak upon a subject which does not properly fall within his jurisdiction. The *Buffalo Medical Journal* accuses Mayor Johnson of neglecting to enforce the methods of sanitary science, and holds him responsible in part for the situation. We are apt in this country to commiserate other countries in which an ignorant populace, as in India, resists the progress of sanitary science—but we should reflect that we, too, have our troubles of this kind, and they are not confined to Cleveland. That city is a very progressive and enlightened one, and we do not believe for a moment that it will follow the lead of its Mayor in this matter. Its many able physicians can doubtless lead public opinion even against the influence of the Honorable Tom Johnson.

Continuous Sneezing for Seven Months.—We strongly suspect that the interesting case of sternutation reported by Massé (*Revue Heb. de Laryngologie, d' Otologie et de Rhinologie*, Feb. 2, 1901) was of hysterical origin. This seems all the more probable from the fact that the affection was promptly cured by the use of an orthopedic apparatus on the spine, for which there seems to have been but little indication. The case occurred in a neurotic girl, aged 16. She had had dyspeptic symptoms, with frequent headaches and facial neuralgia. After a severe attack of influenza she had a dry cough, which ceased rather suddenly and was replaced by paroxysms of sneezing. These paroxysms began on the patient's awakening and continued seven or eight times a minute until she went to sleep. There was a sense of irritation in the nose, and the paroxysms were worse after eating. All treatment was ineffectual until Massé noticed that the spinal column was bent slightly forward. This suggested the use of a corset or supporting apparatus, and the adjustment of this was promptly followed by a cure. All this, we say, looks suspiciously hysterical. There is, in fact, no end to the symptoms of hysteria, and

some of the most interesting and obscure of these stigmata are associated with the respiratory tract. Sneezing has not been frequently observed, but bouts of yawning, and various forms of rapid respiration and other affections of respiration have not infrequently been noted. The use of a simple apparatus or spinal brace would be just the kind of a thing to favorably influence the mind of an hysterical patient and effect a cure. In other words, the use of such an apparatus would be simply a resort to suggestive therapeutics.

Reviews.

"A Handbook of Genito-Urinary Surgery and Venereal Diseases," by Dr. G. M. Phillips, Professor of Genito-Urinary Surgery and Venereal Diseases, Barnes Medical College. Illustrated with half-tone cuts and special drawings by Dr. L. Crusius. St. Louis, Lewis S. Matthews & Co., 1900.

Although a "handbook" it would seem to a reader of this volume that the author might have treated certain important subjects with more consideration than he has done. The portion devoted to venereal diseases is thoroughly practical and relates the author's experience. The portion devoted to genito-urinary surgery, particularly the chapters on the Prostate Gland and on the Surgical Diseases of the Kidney, is markedly deficient. Seven pages are devoted to the diseases of the kidney, and, although some of the diseases of this organ are described, yet others, such as tuberculosis and cystic degeneration, are passed over without a word as to their diagnosis and little more as to their treatment. The only symptoms ascribed to floating kidney "are pain and nervousness, either, or both of which may be paroxysmal or constant." To these indefinite symptoms are added the statement that a twist of the ureter may occur and hydronephrosis may result. But one method of operative treatment is described for the relief of this condition, and this description is hardly sufficient to guide one in the performance of the operation. In describing the operation for varicocele the author makes no mention of the more recent "high" operation for this condition. One can hardly speak of the author's style without criticising it, many of his sentences being entirely unintelligible. The following quotation will give some idea of the difficulty one has in understanding exactly what the author means to convey: "No doubt much of the trouble associated with varicocele is psychic, and largely due to the literature of the advertising quack: for the majority of my patients have shown unmistakable evidence of having seriously studied this free literature, and many times fallen victims to their proposals and become hypochondriacs, either on account of the disease or the treatment: it would be difficult to decide."

Some of the illustrations, particularly the photographs, in this book, are very good. [J. H. G.]

An Index of Symptoms and a Key to Diagnoses. By Ralph Winnington Leftwich, M. D., Late Assistant-Physician to the East London Children's Hospital. Second Edition. New York: William Wood & Co., 1901.

"An Index of Symptoms" is a small book in which the various symptoms of disease are enumerated and beneath each symptom there is a list of all the diseases in which that symptom may occur. As examples, taken at random, delirium is a symptom of 43 diseases, and pale urine, is a symptom of 16. It is to be supposed that if a physician has a patient who passes pale urine, he turns to the list of diseases of which pale urine is a symptom and determines from what diseases his patient may be suffering and then by exclusion arrives at his diagnosis. The book is one of those short-cuts to successful diagnosis which are often so popular with the busy practitioner.

[J. M. S.]

Syphilis of Children.—George Carpenter, M. D., Lond. William Wood & Co. New York. 1901.

It is rare that a busy practitioner has either the time or inclination to give to the profession the minutely observed results of his own large experience in a particular class of patients. This has been done by George Carpenter, who has had exceptional facilities for the study of syphilis in children in several hundred cases in his private practice and in work at the Evelina Hospital for Sick Children.

The book is illustrated by sketches made on the spot to illustrate the clinical memoranda from which the monograph has been compiled. The cutaneous manifestations, the lymphatic glands, mucous membranes, larynx, anal orifice, lungs, spleen, liver, kidneys, heart, pancreas, thymus, thyroid, testicles, and the blood are considered under separate headings. There is a chapter devoted to clinical history and a brief summary. There is a short section on prognosis, and one on treatment. Mercury and chalk is preferred, of which one grain is given three times daily to an infant. Intolerance of the drug is not shown in infants by salivation, because the function is not properly established, but by diarrhea. Intramuscular injections are also advised.

This brochure of 110 pages can be read in an hour, and should prove profitable and helpful to those whose experience has been limited in this class of affections. [E. M.]

A Text-Book of Gynecology—Edited by Charles A. L. Reed.

A. M. M. D., President of the American Medical Association (1900-1901); Gynecologist in the Cincinnati Hospital, etc. New York. D. Appleton & Co. 1901. Pages 900, cloth, \$5.00.

To the preparation of this work the editor has brought the experience of many years of active labor in his chosen field of surgery. He has been ably seconded by some of the best writers in their lines of work, including such well-known names as Hobart Amory Hare, Dercum, Ballantyne, McMurtry, Newman, Sinclair, Mann and Coe. While open to some of the objectionable features of composite works of this kind, such as overlapping of subjects and multiplicity of views, this has largely been overcome by the judicious and truly excellent editorial efforts of Dr. Reed. If composite work should be written at all we heartily endorse the practice that has been adopted in this case of securing the cooperation of men in the various departments of medical science in their synthetic relation to gynecology, whereby the best and most recent views of the various subjects may be obtained in the most succinct form. The confining of the contributors to those who had already acquired considerable reputation as writers and authorities in their various lines has tended also to the same desirable end. A gratifying feature of the book is the retaining of the names of the contributors in the table of contents, whereby, if it be desired, the reader may know whose views he is noting and to whom tribute may be paid. The system adopted throughout the work is a rational one beginning with a thorough review of the history of gynecology and of the general topics bearing on pelvis surgery, such as its nomenclature and radicalism and conservatism in gynecology. A chapter on the general etiology of diseases of women is of special interest, and is from the pen of the editor. The general pathology of the female generative organs includes a study of the pelvic functions of menstruation, ovulation, and pregnancy, and the bacterial origin of inflammatory diseases of the female genitalia, as well as trophic and neoplastic changes. The general therapeutics of gynecology, instruments, and methods of diagnosis are ably discussed by Reed, Herzog, Robb and Potter, while the editor gives a *resume* of the modern methods of antiseptics and of the management of sepsis, shock and hemorrhage. In the presentation of the pathologic conditions of the pelvis an anatomical basis is adopted, proceeding from the external genitalia through the vagina, perineum, uterus, tubes, ovaries, and broad ligaments. Interesting features are the chapters on Cesarean Section and ectopic gestation. We regret that the more recent suggestion of Fritsch fails to find mention in the section on the performance of Cesarean Section: in a certain class of cases it may claim a limited use. The rarer forms of ectopic pregnancy do not find a place in the book, nor do

the curious accidents to which that complication is subject receive extensive mention. The chapter on infections of the Fallopian tubes is well written and shows careful investigation; the illustrations are somewhat idealized, but no doubt will be of value from the standpoint of the student. The literature of malignant deciduoma is by no means complete, nor do we altogether accord with the statement that this condition is a "degenerative malignant disease of the sarcomatous type;" there are undoubted cases of this growth of fetal origin which show true carcinomatous degeneration. The section treating of the pathology of the female urinary apparatus deserves special mention. It comprises a most admirable series of chapters from the pen of Harris, of Chicago, and enters exhaustively into the subject; we fail to find any omission even of the newer phases of this comparatively recently developed branch of surgery. The section on neoplasms of the uterus, tubes, and ovaries is complete. We note with interest that the ovulogenous theory of Wilms in the production of pelvic dermoids is endorsed by the author (Rothrock). Unfortunately the important subject of degenerative changes in uterine fibromyomata is disposed of within the space of less than one page, while the valuable operation of ventral suspension, valuable in the proper cases, is placed very materially in the background to favor the Alexander operation, which it is claimed "unquestionably fulfils the indications in a large majority of simple cases." We do not endorse the suggestion in fixed cases of freeing adhesions through an incision in the vaginal vault with a subsequent Alexander operation to hold the uterus forward. On the whole, however, the book that Dr. Reed has presented the profession is a most admirable exposé of modern gynecology, from which, here and there, the individual gynecologist will differ as to certain methods of treatment and technic according as he has been taught by his experience. The entire subject has been excellently grouped and ably treated. The mechanical work is of the best and the illustrations are instructive and not merely introduced for the purpose of padding. [W. A. N. D.]

Correspondence.

ANTHRAX IN PHILADELPHIA.

By John H. Jopson, M. D., of Philadelphia.

To the Editor of the Philadelphia Medical Journal.
Dear Sir:

The report of two cases of anthrax by Dr. L. H. Mutchler before the Philadelphia Academy of Surgery on May 6th, again brings to the attention of the medical profession of this city, the presence, and apparently increasing numbers of cases of this malignant infection in the community. In December, 1899, Dr. A. A. Ghiskey and myself reported a fatal case before the Philadelphia Pathological Society, and referred to four cases that had been reported or related to us verbally as having previously occurred in Philadelphia, and also remarked on the possible occurrence of other cases which had passed unrecognized or unrecorded. Our case was observed in the Surgical Dispensary service of the Episcopal Hospital. In the eighteen months which have elapsed since that time three other cases have been encountered in the same hospital, two studied by Dr. Mutchler, and one by Dr. E. E. W. Ziven, and Dr. Mutchler was able to refer to ten cases in all as having been observed in Philadelphia in a period of about ten years. It seems highly probable that many more have occurred in that time which have not been reported or recognized. The disease is often so obscure in its symptomatology especially in the pulmonic form, that it might easily be mistaken for something else when occurring sporadically, and the external form might also be confounded with cellulitis, carbuncle or erysipelas, when not seen in its earlier stages. At least fifty percent. of these ten cases were first seen at the Episcopal Hospital, which being situated in the center of an enormous manufacturing district, would naturally attract the cases from the tanneries and morocco factories where most of the patients were employed. Dr. Mutchler proposes to notify the Agricultural Department of his cases, and it would certainly seem to be the duty of every physician who encounters other cases to do the same. Ravenel has pointed out the fact that the present methods of curing hides are notoriously unsafe, and that many of those imported are liable to be infected is well known. Until those trustworthy methods

shall come into general use the employers of those exposed should be urged to guard the health of their workmen as far as possible. Many, if not all of these men, seem ignorant of their danger. Scratches or abrasions of the exposed epidermis are the usual avenues of infection in tanners, and the men should be warned of this source of danger. Other measures for protection would suggest themselves. The problem has been skilfully dealt with in the Bradford Woolen Mills in England, as Bell describes in his article in Allbutt's System, and it would seem to be a good time to suggest an attempt to solve it here.

INSTANTANEOUS DRY HEAT FOR EXTERNAL APPLICATION; ELECTRIC SUBSTITUTE FOR HOT WATER BAG.

By De Forrest Willard, M. D., of Philadelphia.

To the Editor of the Philadelphia Medical Journal.

Electricity being now in use in nearly all of our hospitals and in many private homes, I have found the following use of the current very helpful. It has the advantage of being instantly applicable, and especially at night it saves much trouble and time in the securing of a hot water bag.

The ordinary electric bulb attached to a long wire, which is in common use, can be wrapped in one or two layers of cloth and applied directly to the part affected, the heat being readily regulated by the thickness of the folds. At the first symptoms of a chill, during the premonitory creeps down the spine, such a bulb applied directly between the scapulae is of the greatest comfort, and will often prevent a rigor. It has the advantage, too, that the patient lying in bed can quickly seize it himself as it hangs by his side, and make himself comfortable even before the nurse reaches him.

To the physician also who returns to his office cold and wet, this bulb dropped in beneath his coat between the shoulders, while he sits at his desk, will be the speediest means of making him comfortable. Once tried, it is certain to be repeated.

For local pains in abdomen or chest, and neuralgic pains in the head, it has all the advantages of the hot water bag and never grows cold.

The bare bulb used as a flat iron is also very helpful in rheumatic pains of muscles, in sciatica, etc. Try it!

As a heat producer after operation: as an application for cold feet, etc., it has the special advantage of quick and continuous service.

A QUESTION OF PRIORITY.

By James F. E. Colgan, M. D., of Philadelphia.

To the Editor of the Philadelphia Medical Journal.

Professor Schlatter in his article published in the Philadelphia Medical Journal, April 13th, on "Ligation of the Carotid Artery as a Preliminary Operation to Resection of the Superior Maxilla," states that the first report concerning the ligation of the common carotid as a preliminary operation in operative procedure on the head is from the clinic of Professor C. Reyher, of St. Petersburg. Is not this an error? In the American Medical Recorder for April, 1821, is the report of an operation by Horatio G. Jameson, of Baltimore, Md., in which previous to removing a large tumor of the superior maxilla he ligated the common carotid with an animal ligature. As the patient was alive several years after and in enjoyment of perfect health, the credit of the first successful operation in my opinion belongs to America, and not, as stated in the article, to Russia.

A Case of Poisoning from Hair Dye.—Dr. George Petit (*Independent Medicalist*, 1901, No. 18) reports the case of a woman of 33 who, while confined to her bed after having injured her foot, had her hair cut short. Later, in Budapest, she bought a hair dye, which she used for three years. She grew thin and weak, and showed all the signs of dyspepsia. During the three years she had 16 successive attacks of erysipelas, for which no cause could be found. Petit finally came to the conclusion that the hair dye must be the cause of all these symptoms of systemic intoxication. Examination showed that it contained resorcin. Since she has stopped using the dye, she has grown gradually well. Oddly enough she had herself come to the conclusion that the hair dye was the cause of all her trouble, but tried to hide the fact from her physician.

[M. O.]

Society Reports.

Meeting of the American Pediatric Society.—The twentieth annual meeting was held at Niagara Falls, Greater Buffalo, May 27-29, 1901, at the International Hotel, Monday, May 27. President's address, Dr. Wm. D. Booker, Baltimore. After alluding to the death of Dr. J. H. Fruitnight, the president proceeded to a thorough discussion of the history of summer diarrhea of infants. Its first appearance in this country was in the middle of the eighteenth century, when the colonists had become collected in towns and villages. It had been unknown among the aborigines and was supposed by the American physicians not to have occurred in Europe. The first noteworthy description was by Dr. Benjamin Rush, 1777, under the term cholera infantum. Auretius, however, in the second century, mentioned an epidemic diarrhea of children, occurring in the summer months. Harris, 1650, described it as occurring in England and Claghorn, 1744, as in Minorca. Rosenstein, of Stockholm, 1750, devoted 40 pages to this disease. There followed an exhaustive review, especially of the early American literature, up to about 1830. Dr. Allen Baines of Toronto, reported a case of general arterio-sclerosis in a boy aged ten years, with specimen and microscopic mounts. The case had been observed for about a year before death, but no cause was discovered. Drs. T. M. Rotch and Maynard Ladd, of Boston, reported a case of pernicious Anemia in infancy, emphasizing the value of inhalations of oxygen. As the case was reported as apparently recovering, considerable doubt was expressed in the discussion, as to the diagnosis.

Dr. Frank Spooner Churchill, of Chicago, made a preliminary report of a case of so-called "cyclic albuminuria." He considered the term objectionable as the condition was merely a symptom. A review of the literature had impressed him with two facts, the superficial examinations of the urine made the short length of time that the cases were under observation. No one knows whether these cases would develop into recognizable organic disease or not. The women might develop puerperal eclampsia, the men an interstitial process. His case, that of a boy aged 11, was distinctly one of chronic parenchymatous nephritis, as shown by casts, blood, renal epithelium, and pus in the sediment. Eighty examinations of single specimens had been made, with absence of albumin night and morning and presence in the middle of the day, albumin being increased after exercise in the gymnasium, diminished after rest in bed. The urea percentage was uniformly high but not excessive, considering the age. Phosphates were increased, chlorids low. No generalizations could be drawn from these observations but the case would be reported later and it was worth inquiring whether the conditions leading to these chemic states were immediately or remotely causes of nephritis.

Dr. Rowland G. Freeman, of New York, reported a curious epidemic occurring in the Foundling Hospital. In June, 1899, 82 cases developed either simultaneously or within a few days. These included all of 77 children who spent the day in a certain play room and five of thirty children in an adjoining play room, isolated on account of ringworm. No other cases occurred in the total of 700 inmates. Drowsiness, loss of appetite and fever from 101° to 105°, were symptoms common to all. A digestive disorder was at first suspected but no symptoms developed to justify this diagnosis. One case had marked malarial signs and the plasmodium was found. In seven mild cases, no parasite was demonstrable. The other cases were treated with quinine so successfully that a cure resulted before the order to examine the blood was carried out. In many cases, two grains daily were insufficient, but six grains produced a cure. Celli and Koch and the English Expedition to Sierra Leone, were quoted to establish the susceptibility of young children to malaria. As to etiology some structural changes in the hospital had allowed some pools of stagnant water to form near the play room windows. There had not been time for mosquito larvae to develop since cold weather and there were no indications of bites on the children, so that, if the fever were malarial, inoculation must have occurred in some other manner. In the discussion, influenza was suggested as an explanation. Amaurotic Family Idocy. A. C. Cotton, Chicago. 36 cases had been collected from the literature and the author added one more. The spastic symptoms resembled infantile birth pal-

sy but the diagnosis was established by the Tay-Kingdon spot in the retina. The author expressed the belief, on account of the liability of error in diagnosis, that many cases were overlooked and urged the routine examination of the fundus in all suspicious cases. Note on the Little Finger of the Mongolian Imbecile and of Normal Children. Dr. J. Park West, Bellaire, Ohio. Eight cases were reported, and radiographs exhibited which showed a characteristic curve of the phalanges toward the ring finger. Dr. B. K. Rachford, of Cincinnati, reported a Case of Maternal Impression. The mother was operated on for appendicitis in the third month of pregnancy. The child, when six months old, showed a corresponding line with stitch marks, in the right inguinal region, but no scar tissue was apparent. Drs. Frederick A. Packard and Alfred Hand, Jr., of Philadelphia, made a report on the "Pathologic Anatomy of Cretinism, Showing Specimens of the Atrophied Thyroid and Large Thymus." The discussion branched off into a consideration of the thyroid extract. While the general opinion was favorable to its place in therapy, it was held that its success in cretinism had not been marked and that the improvement had been in all instances thus far known, merely temporary. Drs. Henry Koplick and I. Lichtenstein, of New York, contributed to the "Symptomatology of Cretinism, an Observation, Illustrated by Casts," that the hypothyrenar Eminence of Cretins rises abruptly from the line of the wrist instead of gradually, as in normal individuals.

Dr. J. P. Crozer Griffiths, of Philadelphia, reported the case of a child (colored) aged three months, which was first seen in a moribund condition. On autopsy, it was found that the appendix was gangrenous. He appended an exhaustive review of the literature of appendicitis in infancy. Among 97 cases, the appendix was perforated in 15. In 4, it had descended into the scrotum. Nine cases had been subjected to operation with seven recoveries. In two of the nine cases, operation was undertaken with the diagnosis of intussusception. He also reported a case of Long Continued Laryngeal Stenosis in a child of 20 months. The child began to suffer with dyspnea on February 15 and continued, with some remissions, to grow worse till April 9, when intubation was practiced. The tube was coughed up several times and was left out for a couple of hours on one occasion, otherwise it was retained till April 27. On May 4, the child was doing well but still had stridor or coughing or swallowing. May 5, pneumonia developed. By May 20, the child was well except for a husky voice. The mother insisted that the child had had a similar attack in August and September previous, lasting four weeks and that five of the child's brothers and sisters had suffered similarly while teething or undergoing analogous disturbances, the attack lasting a couple of weeks in each instance. The condition differed from ordinary croup in being persistent, night and day. Diphtheria was excluded by bacteriologic examinations, pressure by enlarged lymphatics, the thymus, etc. on the trachea was excluded by the relief afforded by intubation which located the trouble in the larynx. Pressure of a lymph node on a branch of the pneumogastric has been assigned as a cause of laryngeal spasm, but as Marfan points out, unilateral pressure should not cause bilateral spasm. Edema and papilloma were excluded by examination. The symptoms did not accord at all with laryngismus stridulus. Rhachitis was present and was probably a predisposing cause. Evidently, some family tendency to laryngeal spasm existed. In the discussion, the opinion was expressed that the case was really diphtheritic, the bacilli having been absent at the time of the examination, but the previous attack having been of this nature. Dr. Griffiths did not agree with this theory.

Dr. Wm. F. Northrup, of New York, read a paper, with illustrations, on Glass Sun Rooms on City Roofs, or Winter Playhouses.

Tuesday, May 28. Dr. Charles Gilmore Kerley, of the Davis Hospital, O. P. D., New York, read a paper entitled: "A Study of 551 Cases of Summer Diarrhea." Only 6% of his cases were nursed. 472 were fed on cow's milk, in whole or in part. He considered the expense of proprietary infants' foods a fortunate circumstance. When first seen, his cases had lasted from one to ten days or more. 80 cases recovered in three days, 168 in 4-7 days, the remainder in longer times, for instance, 11 recovered during the third week, 58 in the fourth and fifth weeks, 11 during the sixth and seventh, 6 in the eighth to tenth week. 499 patients were treated to the conclusion of the sickness, 10 resulting fatally. One invariable rule was to stop the milk, on the

ground that it favored the growth of the various bacteria involved. Clinically, it was impossible to differentiate the bacteria causing the disease, nor could the extent of lesions be determined by the apparent severity of the case. In 218 autopsies, in which gross lesions were expected, slight troubles were found and, on the other hand, extensive ulcerations had been found in cases from which little mucus and no blood had been passed. In patients dying within a few hours, a pale, washed-out gut, with enlarged lymph follicles, was found, but no ulcers. Most cases begin gradually, as an intestinal dyspepsia, neither the colon bacillus nor the streptococci being of much importance at first. Milk is recommended only, when the stools become approximately normal. In one instance, 5 months elapsed before it was given and in fifty per cent. of the cases, relapses occurred after beginning milk diet. For the most part, cereal waters were administered, 4 or 5 ounces of barley water being combined with one or two ounces of various broths, or two tablespoonfuls of beef juice, changing from one preparation to another to avoid flagging of the appetite. Brandy should not be given. White of egg mixture has been discarded as not being digested, and as favoring putrefaction as much as milk. It is impossible to give for any length of time a stronger barley water than that containing two tablespoonfuls to the pint. By dextrinizing the barley, the strength may be doubled. Dextrinization must not be carried out at a higher temperature than 100 F. or a disagreeable malty taste will develop. After trying the newer tannin compounds, eudoxin, etc., he had limited the drugs used to four—calomel, castor oil, bismuth subnitrate and opium. The production of bismuth sulphid was necessary, hence if the stools did not become colored, sulphur was added, one grain to ten of bismuth, every hour or two while the patient was awake. Four or five passages a day should be considered normal as maintaining drainage. Irrigation of the colon has been much overdone, it should never be practiced oftener than once in eight hours and not at all without a positive indication. Dr. J. P. Crozer Griffith alluded to experiments showing the lack of value of tannin, opiates, antiseptics, etc. Dr. Henry Koplik advocated albumin water for the acute period and regarded irrigation with salt solution as positively nutrient, on account of the absorption of the salt. The stimulant action of heat should also be considered. Dr. Buckingham objected to the wholesale condemnation of brandy. Dr. L. Emmett Holt said that babies were too often fatigued by having too much done for them. He cited a case in which irrigation had been maintained for seven months, twice daily, to cure a discharge of mucus that ceased, as soon as the irrigations were stopped. However, he believed thoroughly in irrigation at the beginning of an attack. He would add one drug to the list of Dr. Kerley, magnesium sulphate, ten to fifteen grains every hour or two until the stools are practically pure water, usually 120 grains being necessary. Dr. Chapin alluded to the danger of irrigation by kinking of a long tube and thought that, for most cases, it was better to rely on the ordinary rectal tip, elevating the hips. He did not believe in continuing cereals long, quoting a Boston writer: "If cereals are not good for well babies, how can they be good for sick babies?" Otherwise, he agreed with Dr. Kerley. Dr. Adams did not take so favorable view as the author of the possibility of controlling dispensary cases. He cited a case in which irrigation had been carried on from summer into the winter, to relieve a discharge of mucus from the bowel, which was due to adenoids in the pharynx. Dr. Cotton emphasized that a sharp distinction must be drawn between cleansing irrigations, the use of hot water in the bowel for stimulation and the cool sedative flushing in fever. He could not see that there was anything objectionable in the use of egg albumin except the bad odor of sulphuretted hydrogen produced. A long discussion followed, in which many points were reiterated and combatted. Dr. Rotch objected to the term "summer diarrhea," but Dr. Kerley insisted that it was impossible to follow out a proper classification clinically or even to distinguish sharply between functional and organic troubles.

"The Feeding of an Incubator Baby," was the title of a paper read by Dr. Charles W. Townsend, of Boston. The child which was apparently only two weeks premature weighing 2 pounds, 12 ounces. The placenta contained numerous areas of necrosis and, as is usually the case, the infarcts were associated with maternal albuminuria. The heat of the incubator was maintained by a pan of water at 85 F. The birth weight was doubled in two weeks, more than quadrupled in six months and at one year, the child

weighed 17 pounds. He detailed his method of modifying milk, which he preferred to use raw, whenever possible. Each ounce of 10% cream, obtained by skimming off the upper quarter of a bottle of milk after standing five hours, added to a twenty ounce mixture represents 5-10% of fat, 2-10% sugar, 2-10% proteids. Each even tablespoonful of sugar of milk raises the percentage of sugar 2%. The white of one or two eggs may be added, the egg albumin resembling lactalbumin. The infant's progress was uninterrupted and the first tooth was cut at the age of six months and one week. When three months old, the baby was taken into the country and Jersey milk was used. This produced more frequent stools and some gas and Holstein milk was substituted with good results. After the eighth month, a cereal in the form of oatmeal or barley water was added. Usually, he believes in employing the cereal at or before this time, especially if pallor develops. He alluded to a similar case occurring in an infant born at the seventh month.

"The Place of Cereals in Infant Feeding," Dr. Henry D. Chapin, of New York. Believing that their use is well established clinically, he attacked the problem from the scientific standpoint. Our methods of analyzing milk are not sufficiently perfect to warrant too strong insistence on percentage modification of cow's milk, to imitate mother's milk. Ordinarily, we do not distinguish clearly enough between soluble albumin and globulin on the one hand and nucleo-albumin, mainly caseinogen, which contains phosphorus, on the other. Neither is it correct to call everything fat that is extracted by ether. Albumin, globulin, albumose, sugar, etc., could be absorbed after little digestive effort while nucleo-albumin represented in the curds, required a tedious process of digestion. Mammals may be divided into carnivorae, and non-ruminants, for convenience. The milk of each division is similar, a high percentage of proteids being found in carnivorae with short intestines, a high percentage of nucleo-albumin—and hence relative coarseness of curds—in ruminants. Carnivorae double in weight in about ten days after birth, ruminants only after sixty days. During the first days of life, all mammals are nourished by colostrum, which is rich in soluble albumins and sugar and hardly coagulates at all on the addition of rennet. In practice, it is found necessary to begin with 1-8 to 1-4 of the proteid found in human milk and by furnishing additional amounts of carbohydrates, proteid metabolism is diminished, more readily than by increasing the fats. Hence, a modified milk which contains only the percentage of sugar found in mother's milk, is inadequate. Maltose saccharose and lactose all have the same formula $C_{12}H_{22}O_{11}$, and all rotate light to the right. Saccharose is eliminated if introduced into the blood, the other two are assimilated, oxidation depending on enzymes of the blood. Cow's milk contains two sugars, one of which, at least, is different from that of mother's milk and it is impossible to modify cow's milk so as to imitate human milk, physiologically, even if the percentage composition seems to agree perfectly. Both by diminishing the size of curds and by furnishing readily oxidizable nutriment, he believed that the use of cereals was useful and he thought it better to use a simple cereal gruel as a basis rather than let the baby be turned over to a mercenary manufacturer.

In the discussion of these two papers, considerable opposition was manifested toward Dr. Chapin's theory and the general feeling seemed to be that his advocacy of cereal gruels would tend to the use of proprietary preparations. Dr. Rotch criticized his tables of milk analysis as incorrect and alluded to the popular belief, in which he shared, that it would be difficult to get a sample of mule's milk. He acknowledged that barley would favor curdling in smaller particles than plain water as a diluent, but he did not recognize the necessity of securing this end and he preferred to use whey, as containing the more digestible albumin and globulin and sugar of milk. Dr. Koplik favored the general use of modified milk but thought that dextrinized foods were of value in certain cases, especially chronic ones in which the child was poisoned from within its own alimentary tract. Melitose or malt would render the case in more digestible. Dr. Griffith believed that a perfect imitation of human milk was impossible and that good results might be obtained from diverse methods. Dr. Rotch objected to any attempt to harmonize the conflicting theories. Dr. Holt believed that in healthy children, there was no advantage in adding cereals but he favored an occasional change of diet. Dr. Winters had tried cereals and had abandoned them. Dr. Saunders had had good results from

wey and had used cereals to advantage in sick children but did not dvocate them in health. The afternoon session was shortened in order to visit the Pan-American Exposition, where the members were entertained by Dr. Irving M. Snow, of Buffalo. Wednesday morning, May 29. Dr. A. C. Cotton, of Chicago, showed a monster born at the seventh month, although not much larger than a normal fetus of five months, which was passed around with it, for comparison. The principal abnormalities were: webbing and clubbing of the fingers, deficiency of some of the limb bones, as shown by radiographs, ophthalmocoele, deficiency of the cranial bones superiorly, hernia containing intestine and left lobe of liver. The celosomia would locate the disturbance early in the second month or earlier. Hydrocephalus existed but must have developed later or the monster would have been anencephalic.

Dr. Saunders, of Cincinnati, showed a specimen of congenital hypertrophic stenosis of the pylorus, with thickening of the stomach wall but without dilatation. The child was born of healthy parents, without lesion at birth. Vomiting had been frequent and, often, of two nursings at once, so that the diagnosis was made before death and operation advised but refused. The child had died when five weeks old. The stomach, prepared with formalin, was exhibited in contrast with a normal child's stomach similarly prepared. Dr. Holt disputed the diagnosis, calling attention to the suspiciously large number of cases reported lately. He considered the absence of dilatation as against the diagnosis. Various contractions and even hour-glass contraction of the stomach are often diagnosed when the appearance is due to muscular rigidity. Dr. A. L. Benedict, of Buffalo, a guest, while agreeing with the diagnosis, spoke of a fact that he had recently observed, namely that embalming with formalin sometimes caused hardening and fixation of muscularly contracted hollow viscera, to such a degree that mistakes of diagnosis might occur. Dr. Freeman spoke of the differences occurring in normal cases, according to dilatation with gas or contraction. The author referred to the history as establishing the diagnosis and also pointed out the characteristic appearance of the pylorus as seen from the duodenum, resembling the portio vaginalis cervicis uteri. Dr. John Lovett Morse, of Boston, reported a case of a premature infant that was put into a basket lined with blue silk, in order to maintain warmth. A regular incubator was considered unnecessary on account of the warm weather. The child was slightly blue at birth and, after a few weeks, a systolic cardiac murmur was heard intermittently. At six months, slight albuminuria and hematuria and increase of blueness led to a more thorough examination and finally, arsenic was detected in the urine. The blue silk lining of the basket was the only object that could be found containing arsenic. Except for an exacerbation due to an epidemic coryza, the case progressed favorably. Dr. Samuel S. Adams, of Washington, showed eight temperature charts of children from two to eleven years old with pulmonary tuberculosis in the third stage, most of them having cavities. The temperature fluctuated widely between 95 and 105.6 with no correspondence in other symptoms, the children having neither chill, sweat, loss of appetite, nervousness, malaise, etc., at the time of the fluctuation. Dr. Holt thought that there must be some other cause than tuberculosis, for example a streptococcal process in the lungs, to account for the fluctuation. Dr. L. Emmett Holt, of New York, reported a case of diphtheria of the conjunctiva, yielding promptly to antitoxin. General symptoms were slight, the local lesion conspicuous. He also reported a case of gastric hemorrhage without obvious escape of blood by the stools, occurring on the second day after birth and promptly relieved by suprarenal extract, one grain every hour for twelve doses. The last few doses were taken with difficulty on account of the puckering of the esophagus. The child subsequently did well, there being no hemorrhage when the cord came away. A child of the same parents had previously died of similar hemorrhage. A friend of his had used the same method successfully, so far as the gastro-intestinal hemorrhage was concerned, but the child died later, apparently from internal hemorrhage. He also reported a case of protracted high temperature, from January 10 to May 5, when death ensued. For several days, the temperature was very high, reaching 106 and pneumonia was diagnosed from the physical signs. For the most part, however, only a few rales, feeble breathing and slight dullness, bilaterally, were noted. Examination for the plasmodium, five Widal tests, attempted cultures

from the blood, examination of sputum, etc., were negative. There were gastro-enteric symptoms with discharge of mucus. At the autopsy, broncho-pneumonia, universal adhesions of the lungs, a pocket of 15 c.c. of pus in the right lower lobe and a sacculated empyema containing 60 c.c. on the diaphragmatic surface of the left lung were found. In the middle of the sickness, the leucocytes amounted to 22,000, falling to 14,000 and 11,000. Dr. Morse reported a case of oozing from forceps wounds, in which suprarenal powder applied locally had no effect. Finally Monssel's solution and digital pressure for twelve hours were resorted to, successfully. Drs. Rotch and Buckingham reported a case of prolonged fever in which the pathologic diagnosis was lymphogenous pneumonia, the pneumococcus being present. Dr. Chapin reported a case of elevation of temperature, recurring regularly every fifth day, unexplainable and not yielding to antimalarial treatment, but gradually recovering. He had seen four or five cases of ocular diphtheria in which antitoxin was used but he believed the cure had been due rather to local treatment. Dr. Carr, in regard to suprarenal extract, quoted Bates's experiments which show that an aqueous solution must be used. Dr. J. P. Wilson, of Philadelphia, spoke of the usefulness of suprarenal extract in adult cases, mentioning one of purpura hemorrhagica, with filling of the bladder with blood, occurring in the course of gonorrhea. He urged examination of the heart in all protracted fevers, without obvious explanation, for some form of endocarditis, not necessarily ulcerative, might be the cause. Dr. Rotch mentioned the case of an oculist's child, suffering from conjunctival diphtheria, in which local measures had been unavailing but which yielded promptly to antitoxin. Dr. Holt emphasized the difference between hemorrhages in the new born and hemophilia, in that infants either die or recover without further hemorrhagic tendency. Dr. Chapin disagreed with this, alluding to Dr. Holt's case and to one of his own in which two children of the same family had hemorrhages within a day or two after birth and the mother herself suffered from hemophilia. Dr. Holt mentioned a method of obtaining sputum in young children, by the passage of the tube into the esophagus, while the stomach was empty. Dr. Harold Williams, of Boston, reported a case of Appendicitis occurring with Measles. The signs pointing to the appendix were obscure though there was a history of gastro-enteric disturbances. Measles had previously occurred so that the case was considered from the side of the bowel till the eruption made the one diagnosis positive. The next day after the appearance of the eruption, however, it became evident that measles was not the only condition present and operation was performed, resulting in finding a slightly gangrenous appendix. Temperature fell to normal the next day and convalescence was rapid. Dr. W. S. Christopher, of Chicago, read a paper on Physical Measurements at Puberty, their Significance, Variation and Applications, based on studies made for the Educational Department of Chicago. Tables of weight, height, rapidity of growth, vital capacity and hand grip were shown, giving both averages and a "belt" of normal variations from the average. Immediately before puberty, there is a decline of the life processes, followed by an exaltation for a couple of years or thereabouts, of all the life processes enumerated. This wave begins earlier and lasts a shorter time in girls. As compared with boys, this exaltation in girls is more marked in weight and height, less so in the other aspects. At puberty mortality is low and morbidity high, neuroses, psychoses, neurasthenia, deformities and anemias being the chief diseases noted. There is a wider "belt" of normal deviation from the average at puberty, and a corresponding accentuation of individualism, as compared with other periods of childhood. He had noted that the inmates of a school to which boys are committed by the criminal courts, fell below the averages of boys of corresponding ages at other schools, the difference being more and more marked with advancing age. The following officers were elected: President, Dr. W. S. Christopher, Chicago; first vice-president, Dr. John Dornung, New York; second vice-president, Dr. Charles W. Townsend, Boston; secretary, Dr. Samuel S. Adams, Washington; treasurer, Dr. J. Park West, Bellaire, O.; editor and recorder, Dr. Walter Lester Carr, New York; council, Dr. A. D. Blackader, Wm. Osler, C. P. Putnum, F. Forchheimer, J. C. Wilson, F. M. Crandall, T. M. Rotch.

The next meeting will be held in Boston.

American Laryngological Association.

The twenty-third annual Congress of the American Laryngological Association opened in Dwight Hall, Yale College, Monday morning, May 27th. President Henry L. Swain in the chair. After the roll call and reception of guests, President Hadley, of Yale College, welcomed the members in the name of the college in a few well-chosen and felicitous remarks.

President Swain then delivered his address, in which he took for his text the education of the medical man of the future. The first paper that was read after the meeting was formally opened was by Jonathan Wright, M. D., of Brooklyn, N. Y., entitled, "A Leaf From the Ancient History of the Anatomy of Nasal Catarrh."

Then Dr. A. Coolidge, Jr., Boston, Mass., discussed Asymmetry of the Nasal Cavities.

In this community at least, asymmetry of the nasal passages, to a greater or less degree, is so common that it might almost be considered the rule and not the exception. It is commonly observed that in cases of deflection of the septum the turbinate body opposite a concavity is enlarged, and the one opposite the convexity is small. The causes assigned for this condition come under three heads: First, that the deviation of the septum is primary, and that the accompanying changes in the turbinates are due either to changes brought about by the inspired air current, or to pressure on the turbinate. Second, that deviations of the septum are secondarily caused by a primary change in the shape of the turbinates, and third, that both the deflected septum and the asymmetrical turbinates and outer wall are due to a common asymmetrical development.

Reflex Epilepsy from Nasal Disease Successfully Treated by the Removal of the Intra-nasal Cause," was the subject of a paper read by Dr. John O. Roe, of Rochester, N. Y., in which, after saying that the pathology of epilepsy is as yet an unwritten chapter in the history of the disease, and that the exciting cause generally resides in some part of the body outside of the brain, he reports several cases which had come under his observation in which the removal of an intra-nasal cause had caused a cessation of the seizures.

Dr. Arthur Ames Bliss, of Philadelphia, read a paper on the Supra-Lubal Operation (Dr. Harrison Allen's) for deflection of the nasal septum. The cases peculiarly adapted to this operation, are those in which there is a straight or but slightly curved deflection of the nasal septum above the anterior nasal spine with no overhang, with an actual bend of the spine itself to the narrower side of the nose.

Henry L. Wagner, M. D., of San Francisco, Cal., presented a radiograph, showing a large metallic disc in the esophagus. The home remedy of inverting the boy had been tried, with no result, and the boy, five years old, had been brought to the clinic. A suitable diet had been ordered in hopes that the telephone check, as his mother said, should take the orthodox course through an alimentary canal. This was tried, but the boy constantly complained of a metallic taste, and an incessant pain in the neck, and in the stomach (reflex) and had at last vomited, not the telephone check, but a brass disc considerably larger. The disc was shown. The narrator also presented a case of Epipharyngeal Lympho-sarcoma in a boy. This is rarely found in children. The growth was neither lobulated or soft to the touch of the probe, as sarcomata are said to be in this region, but its surface was perfectly round and smooth, and its texture very dense. The growth was removed, with some alleviation of symptoms. Soon after there was paralysis and ptosis of the left eye, showing that the morbid process had invaded the brain. An otitis media purulenta afterwards set in, and the patient died about four months after being first seen.

Dr. John Henry Rhodes, of Chicago, read a paper on "Chancre of the Tonsil," with report on four cases under his own observation, and a table of 31 others. He is of the opinion that there are many of these cases that are acquired innocently. He is also of the opinion that there are many of such cases that are not properly diagnosed, being taken for a recurrent tonsillitis. He arrives at the following conclusions: (1) Chancre of the tonsil is often unrecognized because hypertrophy and inflammation are so frequent, and are so closely simulated in the earlier symptoms, which often differ little from an ordinary sore throat. (2) An enlarged and indurated tonsil with a superficial ulcer

on its surface, accompanied by enlargement and induration of the continuous submaxillary gland, and which is unchanged by a long course of treatment renders a diagnosis of chancre probable. (3) The character of the chancre depends upon the original condition of the tonsil as to size, density, the amount of follicular inflammation and the coincidence of a mixed infection. (4) A certain diagnosis cannot usually be made until the general eruption of the disease. (5) The explosion of the disease is no more severe than in chancre elsewhere. (6) The disease is contracted by direct contact or by various media carrying the virus. (7) When we consider the frightful contagiousness of syphilis, and the frequency with which it is conveyed to innocent persons, the most careful use of throat, nose, dental and other surgical instruments, clinical thermometers, etc., is necessary. (8) Separate instruments should be used for examination and treatment of known syphilitics, but the possibility of contamination before the existence of the lues has been recognized make it imperative that every operator should employ a rapid and efficient disinfection or sterilization of instruments after the examination or treatment of every patient. (9) Most careful instructions should be given patients as to the necessity of sufficient isolation, the methods of infection, and the period of danger, and the use of individual household and other utensils should be enjoined.
